Speaking only of recent American writers, I may allude to a very able discussion on "The Borderline Between Sanity and Insanity," in 1898, by our lately deceased confrère, Dr. E. C. Runge,[3] before the American Medico-Psychological Association, in which he uses the following language: "When we admit that a case of so-called cerebral neurasthenia may at times simulate the profound psychic changes of the prodromal phase of dementia paralytica so closely as to render an error of diagnosis not only possible but excusable, we put neurasthenia at once in its proper place. Every neurasthenic is, to a variable degree, a psychoasthenic. The question is one of degree only, the varying intensity of the disease can not possibly affect its fundamental character." Runge also shows that the only difference between delirium and postfebrile insanity is often simply one of duration. The conclusion which he formulated seems to me irresistible, namely, that "insanity is the symptom of any pathologic process implicating the psychic centers of the brain, hence the borderline between sanity and insanity lies at the point where brain disease parts ways with brain health; by brain being meant its psychic centers."

In this connection I may be pardoned an allusion to a discussion of this point by myself before this Section two years ago.[4] In writing on "Hospitals for the Neuropathic and Psychopathic," I said: "Either the two classes belong together to a great extent or their separate needs have been largely ignored." I then showed how a large proportion of the "neurotic" are really insane, and are found among the inmates of public asylums, while "nervous prostration" is often a polite misnomer for insanity, the only distinction between a large number of patients in any private sanitarium and those in public hospitals for insane being that the former are blessed with longer purses. The phobias, the obsessions, hysterias, hypochondrias, the confirmed drug and drink victims are certainly cases of mental as distinguished from nervous disease. No definition could be framed which would include insanity and exclude these cases. It is also true that the hemiplegias, the apoplexies, the toxemias and even the heart, kidney and arterial diseases, accompanied by disordered brain function, have insanity as a complication. Nevertheless, these cases are not generally regarded as insanities, either by the profession or the public, though technically they are such, for they are "a seriously [and persistently] impaired condition of the mental functions involving the intellect, emotions or will or one or more of these faculties, exclusive of temporary states produced by and accompanying acute intoxications or acute febrile diseases.[5]

And here the fact is strongly brought out that the word "insanity" means everything or nothing, according to the use made of it by different persons. Insanity is very generally accepted as a generic term for all abnormal mental action produced by disease or defect or disorder of brain. In another sense it is applied only to offensive or dangerous mental states, which causes a natural and nearly universal feeling that we do not wish it applied to ourselves or our friends, however appropriate it may be for others. It has, in a lesser degree, the suggestion about it of the older word "lunacy," which in its day was equivalent to possession by the devil. Hence, it is abhorrent to call neurasthenia and hysteria *et id genus omne*—"insanity." This confusion will, in my opinion, ultimately result in the abandonment of the word. Its meaning in law, in medicine, in common parlance and in psychology is variable and confused to the last degree. No complete nor generally acceptable definition of it has been or can be formulated. It is, we often remind ourselves, only a symptom of brain disease still more or less obscure in its nature, and yet we must, in a practical way, consider and treat it as a disease in and of itself. Psychosis is a preferable term. It is less objectionable and more indefinite, and I submit that an indefinite word is better calculated to define an indefinite thing. The meaning of insanity can not be properly limited to offensive or dangerous cases. The neurasthenias are, all will admit, psychoses, but the insanities are psychoses in precisely the same sense and it seems inaccurate to call one psychosis insane and another sane simply to please the ear unless there be some radical difference in fundamental nature. If "major" and "minor" are acceptable, no alienist would object, even though the word "psychosis," like "hysteria," may be mildly objected to. There are many patients who do not care to be told they have hysteria, either "major" or "minor,' and of course nothing will overcome the objection felt by wounded pride to acknowledging infirmity in the highest faculties. If, however, psychosis be accepted, a gain in clearness will have been won and the unnecessarily painful associations of "lunacy" and "insanity" will be avoided. Furthermore, along with the passing of neurasthenia, there should be a passing of the word insanity and with it an unnecessary opprobrium will also have disappeared.

[5] Century Dictionary (["and persistently"] is added from the "Standard Dictionary").

I may advert here to another utterance showing the obscurity of the word insanity. In an ingenious article in a recent issue of the *Alienist and Neurologist,*[6] Dr. J. W. Wherry proposes that the word insanity shall be applied only to delusional states, but as insanity is fully as much a symptom of emotional and volitional, as of intellectual states, the proposal seems impracticable. Furthermore, all the phobias and obsessions belonging to conditions not generally regarded as insanity would have to be renamed.

The delirium of fever differs from insanity only in duration and not in kind. If it is insanity when continued three months, it is insanity when continued three hours, at least there is nothing to show at what point a dividing line exists, and to give widely different names to stages of the same disease leads only to confusion. We may correctly say a psychosis complicates a fever, whether the complication be of three hours' or of three months' duration. The phobias of the neurasthenic, the obsessions of the hysteric, the illusions of the hypochondriac differ only from the wildest delusions of the maniac in degree; at least, if they differ in kind, we are not yet prepared to demonstrate the fact. The "phobia" of the neurasthenic which transforms *muscæ volitantes* into threatened blindness or creates cancer or heart disease out of nothing is insanity, even though it has been unrecognized by our neurologic brethren.

I can agree, from my own experience, with Dr. Dana's statement that very many cases of so-called climacteric insanity have always been psychopathic and have had attacks of mania or severe neurasthenia in early life from which they have never fully recovered.

One further reflection and I am done. The last idea I wish to advance is that the progress made in classification in nervous and mental diseases of late has largely been in the direction of obliterating lines rather than in drawing new or closer ones.

In the classification of insanity, the views of Kraepelin which meet with general favor have been characterized by throwing together cases formerly classified separately. If there was formerly any agreement as to species of insanity, certainly "mania," "melancholia" and "dementia" were considered stable and well defined, but the line between the two first has been erased by forming one group, embracing largely the acquired insanities and terming them the "manic-depressive insanities" or "mania-melancholias," while dementia has been applied to another great group of the primary insanities with the prefix "precocious" and subdivisions into "hebephrenic," "catatonic" and "paranoid," thus leaving "paranoia," while in the differentiating stage, somewhat suspended in midair. This conception of "dementia precox" modifies greatly the meaning of "dementia" as formerly understood and includes an extensive class of cases formerly not classified as dementia, and, indeed, not possessing the character formerly attributed to dementia by English writers.

Now turning to Dr. Dana's proposal that the neurasthenias shall largely be classified as psycho-neuroses or "phrenasthenia," thus bringing them under the category of mental diseases—or, as one may say, with bated breath, "the insanities"—we see an opinion expressed by the neurologist with which the alienist can heartily concur and in fact a proposition which is not new to the latter. At the same time this means the destruction of lines formerly rather generally agreed on of distinction between insanity and various so-called neuroses (hysteria, neurasthenia, hypochondria, the various phobias and obsessions), and the transfer of a large group from the field of neurology to that of psychiatry.

On the whole, I fear I may be accused, in writing on this subject, of writing on something non-existent, or at least on a most vague and indefinite subject, and this I must admit, only urging in my own defense that we are not yet in a position to secure scientific accuracy and will not be until the changes from health to disease going on in the brain, of which insanity is the symptom, can be localized and qualitatively and quantitatively understood. We may appear at present to be going backward, changing and undoing the work of our predecessors, rather than advancing; nevertheless, true progress frequently requires such a process as new lines of investigation are discovered and new working hypotheses are adopted.

MEDICAL PRACTICE IN SIBERIA.

G. B. HASSIN, M.D.
CHICAGO.

REQUIREMENTS FOR MEDICAL PRACTICE.

The rules of medical practice in Siberia are the same as in European Russia; that is, for the whole Russian Empire, from the Baltic Sea and the German-Austrian frontier up to the Pacific Ocean—Vladivostok and Port Arthur—there is one medical law: For the right of practicing medicine one must be graduated from one of the ten imperial universities of Russia. The university can be attended only by those graduated from a classical high school (eight years' studies), the so-called gymnasium, while the time of study in the university is not less than five years. After graduation, each student is permitted to take the state examinations, always oral. If the student be successful in these "final" examinations, he gets his diploma, and the right to practice medicine throughout the Russian empire and to fill any medical position in the army, navy or civil services, etc. For the higher medical positions, as well as for professorships, the physician must take new examinations on certain subjects, prepare a scientific work and defend the same openly. Then he gets the second, highest medical degree, *doctor medicinæ* (doctor of medicine).

Thus the medical practice in Siberia is in the hands of people who have received a complete preliminary general education and a special medical one from a university.

UNIVERSITY EDUCATIONAL DISTRICTS.

The Russian government decreed in 1899 that each university should accept only students belonging to the educational district in which the university is located, so that a graduate from the Siberian gymnasium can attend only the University of Tomsk, but by no means the University of Kazan or Moscow. These universities can be attended only by students from their respective educational districts. A graduate from the gymnasium in Odessa, for instance, can study medicine only in Odessa, but not in Moscow or Petersburg.

The majority of young physicians in Siberia are thus graduates from the University of Tomsk, although there are very many physicians in active practice who were graduated from other universities.

---

[6] Alienist and Neurologist, April, 1904, p. 147.

GENERAL PRACTITIONERS AND MEDICAL OFFICIALS.

When a young physician in Russia gets his diploma, he has in view either to practice in some city as a general practitioner or specialist ("voluntary" practitioner), or to get a position as a district or county physician, military physician, etc. All these positions are more or less paid, so that the Russian physician is in very many cases practically independent of private practice, forming the class of so-called "serving" physicians. The latter class is in Russia quite numerous, especially in the small cities of central, north and east Russia, being comparatively less numerous in the larger cities. In Siberia, where the population is sparse, the acting physicians mainly belong to this class. For instance, to take the city where I was practicing (Yenisseysk, with a population of 10,000), there were seven physicians for the whole city. Three were general practitioners, and five held salaried positions as follows: One was a physician in the gold mines of the Yenisseysk district; one was city physician; one physician in the city hospital and for the prisoners; one was district physician, and one in the city dispensary. The same comparative proportion between these two classes of medical men exists in other cities of Siberia. Thus in Krasnoyarsk, the capital of the province of Yenisseysk, with a population of 30,000, there were in my time (1898-1901) twenty-four physicians, and all except one occupied some official medical position.

SALARIES OF MEDICAL OFFICERS.

Regarding the material part of the latter, I will give here the amount of salaries of my colleagues of the city Yenisseysk: The doctor of the gold mines received 2,500-4,000 roubles a year (about $1,250-$2,000), depending on the number of workmen in the mines, counting 1 rouble—50 cents—per capita; the city physician received 1,000 roubles a year; the physician of the city hospital and jail, 1,000 roubles (with a flat, heating and light); the district physician, 1,200 roubles; the dispensary physician (two hours daily), 600 roubles. It is obvious that the salary alone can not always secure a good living, therefore, some physicians also resort to private practice which, however, is entirely in the hands of the "voluntary" physicians.

SUPPLY OF PHYSICIANS IN THE CITIES.

From what was said above, it will be seen that a city of 10,000 population, with eight physicians, is quite sufficiently supplied with medical assistance. Generally speaking, the cities of Siberia, and still more so those in Russia, feel no lack of medical aid, while in some parts of Russia there is even an abundance of physicians.

SUPPLY OF PHYSICIANS IN RURAL DISTRICTS.

The same can not be said regarding the rural population. Siberia mostly consists of villages; there are but few cities. The villages are scattered at great distances from each other, the usual distance being 13 to 15 versts, or about 10 miles. In places remote from the populous districts the villages are 30 to 50 miles apart (so is it, for instance, in the province of Yenisseysk on the rivers of Chuna and Mura). It is evident that a physician can not live from private practice in a village, and the government can not afford to have even one physician for each three villages; therefore, each Siberian province is divided into medical districts.

THE DISTRICT PHYSICIAN.

Before the year 1898 the province Yenisseysk, which contains about 1,000,000 square miles, was divided into six districts. For each district there were two physicians—one for purely medical purposes, the other one for medicolegal ones. Both physicians used to live in the capital of the district. In case of need, as, for instance, an epidemic, the physician was notified by the authorities through a special messenger or mail which visits the villages once a week and the cities twice or three times a week (where the train passes through a village or town the mail may be obtained every day). The physician then started to the corresponding place on his *povoska* (traveling sleigh). On account of the long distances between the villages and the obsolete methods of communication, much time is lost before the necessary point is reached. It is obvious that good and prompt medical services are, under such conditions, entirely impossible.

OFFICIAL VISITATIONS OF THE DISTRICT PHYSICIAN.

The district was officially visited by the physicians once a year, usually during the summer time. Some parts of his district were visited oftener, depending on the distance, but practically the population was all the time without any medical assistance, as in urgent cases it was impossible to get the doctor. During epidemics, when many villages needed the doctor at the same time, he traveled from one village to another, merely recording the fact that such or such an epidemic exists, the number of the sick, and, finally, making a corresponding report to the medical authorities of the province. So it was with me.

PERSONAL EXPERIENCES.

In December, 1897, the medical board of the province of Yenisseysk sent me to one of the remote districts of this province to help out the district physician on account of an epidemic of typhoid fever. The district physician was busy in other parts of his vast district, and, therefore, could not himself visit the place where I was sent. I started immediately from Krasnoyarsk, traveled more than 800 miles, passed through numerous villages, having found but one case of acute tuberculosis, and very many cases of measles. Of course, I could not do anything good for the unhappy children, as I had to visit during one month a large district, and one or two hours on an average was all the time I could spend in each village; otherwise I would be unable to return to my medical duties at the necessary time.

UNHYGIENIC CONDITIONS.

The hygienic conditions of peasant life in Siberia are extremely bad. The whole dwelling often consists of a single large room, which is ventilated in the winter time by opening the door for a few seconds. A flood of cold air thus fills the room, so that the ventilation brings cold simultaneously with fresh air. The more well-to-do peasants have two or three rooms; one is kept always clean for occasional guests or officials. The crowded, dirty conditions of life, together with the absence of good and proper nourishment, are the cause why epidemic diseases prevail among the peasants in Siberian villages with high mortality and frequent complications.

MEDICAL AID.

The physician during his official trips carries a small "drug store," distributing medicines *gratis*, of course, to the patients. It is obvious that a patient with a chronic disease, waiting about a year for the doctor's call, can not be even a little bit improved from taking a few powders or a tincture. The chronic diseases which prevail most are rheumatism, bronchitis, and all kinds of gastro-intestinal and venereal troubles. The existence of such a system of medical services was too absurd, and was recognized as such by every physician in charge of a district practice. When I returned from my trip, I asked my colleague, the district physician for about twelve years, what was the aim of his useless services for so many years. He answered: "The necessity to feed my family." Even if there were some dose of usefulness in this system of medical practice, it could in no way justify the immense expenses of government and the population.

Since 1898 some reforms have been made in the medical practice of Siberia, namely, each of the six districts was divided into smaller portions with one physician in each. The physician was given an assistant and one midwife. The Yenisseysk district, for instance, was divided into three smaller districts with three physicians, and the latter had to live, not in the capital of the district, but in the villages, according to the number of inhabitants. The office of a separate coroner physician was abolished, the medicolegal duties being placed in the hands of the district physician.

THE "FELDSHER" ASSISTANT.

The physician's assistant, the so-called "feldsher," is something like a trained nurse, but with a broader medical education. Each feldsher, according to the present laws of Russia, must have a fair preliminary education, attend three or four years a medical school, which is usually connected with some large hospital, and having passed successfully the examinations gets certain rights to practice medicine, namely, in localities where there are no physicians. The feldshers have, in the majority of cases, a good practical training, can sometimes make correct diagnosis and successfully carry out the corresponding treatment. They are very numerous in Russia, playing an important part in the medical life of the rural population, not only of Siberia, but even of Russia, as they supply the lack of physicians and medical assistance which is felt to such an extent in Siberia.

MEDICAL FACILITIES.

The reforms of medical practice in Siberia have been carried out, but the aim was not reached, as three physicians instead of one for a district larger than the State of Illinois and with obsolete methods of communication, can not be of much avail to the population. The latter does not benefit much, from the fact that the doctor instead of ten days or more has to travel (with horses) only three days, so that the result is an immense increase of the expenses with no practical good results. The physician in such circumstances passes most of his time in his traveling sleigh, has very little rest and no moral satisfaction. Therefore, more or less conscientious physicians, with good intentions, try to abandon such an useless play and to establish themselves in some city or not far from even a very small town. Some of the district or county physicians possess small hospitals with a few beds, but such hospitals are not of much use, as they lack proper accommodations and sufficient size.

THE DISTRICT PHYSICIAN AND MEDICAL SCIENCE.

The physician being entirely alone, far from his colleagues of the town, must work successfully in all branches of medical science, be, so to say, a specialist in all branches of medicine, so that there is absolutely no possibility or chance of becoming in time a useful contributor to the science.

THE ZEMSTVO OR PROVINCIAL COUNCIL.

In European Russia a similar system of medical practice in the villages exists, but in more perfect conditions, thanks to the fact that it is not in the hands of the government, but in those of the *zemstvos*, the provincial councils. The conditions of medical practice there are much better, and the so-called *zemstvo* physicians play in Russia a great rôle, not only in the medical or sanitary life of the country, but also in civilizing the population, as well as in contributing to medical science. Some of the zemstvo doctors have appeared as great physicians, as, for instance, Vladimiroff (the author of the so-called Mikulicz-Vladimiroff operation), Razumovsky (professor of surgery in the University of Kazan), Komarovich, Yakovenko, etc., but in Siberia medicine, one may say, exists as yet in an embryonic state, this largely depending on the ignorance and rarity of the population as well as on the lack of means.

THE HOSPITALS.

I would like to say a few words regarding the condition of Siberian hospitals. These may be divided into private (i. e., founded from private donations) and governmental ones. The latter are in the hands of an obsolete institution, "the department of public health." The private hospitals are conducted most satisfactorily and correspond completely to all needs of science, but such hospitals are very few, almost exclusively in Irkutsk and Tomsk, the two largest cities of Siberia. The governmental hospitals, which exist in every town of Siberia, are in such a horrible condition that I would like better to give here the description of one of them by Dr. Ssalishtcheff, late professor of clinical surgery in the Imperial University of Tomsk,[1] made by him in an article published in 1897.

DESCRIPTION OF A PUBLIC HOSPITAL.

"The surgical clinic," says Ssalishtcheff, "is, together with the hospital clinic for internal diseases, under the supervision of the Department of Public Health. This hospital consists of two one-story buildings—one for males, the other for females. For the male surgical patients there are three rooms in the former, while patients with internal diseases are also occasionally placed in the same rooms. The fourth room serves for surgical operations. In the female department there are no separate rooms for surgical patients, who are there placed together with patients suffering with other diseases—for instance, syphilis, internal diseases, etc. The hospital has no separate rooms for infectious diseases, so that patients with ulcerations, suppurations, erysipelas, gangrene and inoperable cancers and those who are going to be operated on are all accumulated in one large ward 'for the sake of isolation.' This ward opens into a corridor about six and a half feet wide, into which open also the other wards of the surgical department. This hall is 'ventilated' at both ends through the exits into the anterooms, while at the same time mephitic fumes pour in from the most primitive privies.

"Beside this, in this corridor there meet every morning a great many new patients, who gradually abandon this place toward 12 or 1 p. m., leaving their *aroma.* These patients are usually dressed in dirty sheepskin coats and dirty, wet felt boots. It is obvious that the isolation of patients in the large ward can not even be thought of. The best room, the so-called 'paradise,' serves for operations as well as for examination of new patients, but the room is far from corresponding to the rules of hygiene. In this room there are eight patients; each of them has about 25 cubic yards of air and about 7 square yards of floor space, with the ceiling about 10.5 feet high—i. e., one-half the minimum required by hygiene. In the large ward the patients have considerably less cubic feet of air and floor space. The air is in all the rooms reeking with CO_2; according to Timasheff, the average proportion is about 2 per thousand. Such a horrible antihygienic condition of the hospitals is not encountered in the zemstvo (provincial council) hospitals of even the smallest towns of European Russia.

---

[1] Arch. für klinische Chirurgie, 1897, liv, No. 1, p. 135, etc.

"On account of lack of beds, the patients often have to lie on the floor. The rooms are poorly lighted through small, frost-covered windows. The wards are cold during the winter time, while the nurses live constantly there with all their household effects. Near the beds of the patients there are placed the most primitive, malodorous night-stools, and everywhere there naturally reigns an unavoidable but yet tremendous dirt. Dr. Timasheff found that about 20,000 to 89,000 bacteria fall on the surface of each square meter, and in the surgical room, during operations, 295 bacteria fall on one square decimeter in the course of five minutes, and 600 bacteria in ten minutes. Despite the fact that it was so hazardous." Ssalishtcheff continues, "to operate among such circumstances, we gradually succeeded in performing the most difficult and complicated operations, and, in the great majority of cases, with the best results.

In the above-described sad conditions are the hospitals in the majority of small Siberian cities, although lately new hospitals have been erected, as, for instance, in Yenissevsk, but with such inadequate equipment and facilities that one can not even think of carrying out any scientific treatment, and still less any scientific researches.

CLINICAL AND HISTOLOGIC OBSERVATIONS ON SYMPATHETIC OPHTHALMIA.*

C. A. VEASEY, A.M., M.D.
Chief of Ophthalmic Clinic and Assistant Ophthalmic Surgeon, Jefferson Medical College Hospital; Ophthalmic Surgeon, Methodist Episcopal Hospital, etc.
PHILADELPHIA.

At a meeting of this Section five years ago, Gifford, of Omaha, advocated the employment of large doses of salicylate of sodium in the treatment of sympathetic ophthalmia, his experience with the remedy having been such that he said, "I do not hesitate to recommend it as the most important remedy that I know for the disease." His method of employing the drug is to administer from "10 to 13 grains in the course of 16 to 18 hours for each 10 pounds of the patient's weight," preferably in brandy, 15 grains to the teaspoonful, followed by a copious draught of water. If there is any indication of heart disease, it is, of course, necessary to begin with smaller doses. In the general discussion which followed, but one of the members present reported any experience in the use of the drug in this class of cases; and, as the number of cases of sympathetic ophthalmia observed by any ophthalmic surgeon during the course of the disease must be relatively small, I venture to report, in some detail, the histories of two cases treated within the past few years, with the hope that in the discussion, which I trust will follow, will be brought out the experience of the members regarding the best methods of dealing with this much-dreaded affection.

Case 1.—F. S., male, aged 24 years, was first examined June 19, 1902.

History.—Eight years before he had been struck on the left eye, in the ciliary region, by a piece of glass which he thought had penetrated the eyeball. He was at once taken to a hospital, where an operation was performed, but the nature of the operation he does not know. The piece of glass was not found. The inflammatory symptoms continued for many months before the eye became white and quiet, and no vision remained. From this time on, at varied intervals, sometimes occurring as frequently as every two or three months, there appeared attacks of redness in the right eye, together with slight dread of light and inability to use the eye for continued near-work, always preceded by one or two days of redness and tenderness of the left eye. For this condition he had consulted ophthalmic surgeons at different hospitals, always being advised to have the left eye enucleated, and always declining to follow the advice. Four weeks before my examination he was struck by a baseball on the affected eye. At the time of the accident both eyes were perfectly quiet, but on the following day severe inflammatory symptoms appeared in the left, the eye being very red and painful on pressure. Three days before I was consulted, the vision of the right eye began to fail rapidly, and when I saw the patient was equal only to 6/45. It had commenced without any premonition, and there had been no symptoms of redness or irritation of any character in that eye, with the exception of a desire to avoid very bright light.

Examination.—There was found in the right eye a somewhat hazy cornea with numerous punctate spots on the posterior surface, especially in the lower part, a very sluggish moderately contracted pupil, scarcely any reaction to light being detected; more spots, or deposit, on the anterior lens capsule in the pupillary space, and a very hazy vitreous with only a red glare from the fundus There was slight ciliary injection and considerable photophobia, though no point of special tenderness could be detected in the ciliary region. In the left eye there was also moderate ciliary injection, considerable tenderness on pressure, especially over one point in the ciliary region and the tension was markedly diminished. The cornea was normal, and the pupil was entirely closed, the iris being drawn into a corneo-scleral wound below.

Evidently the piece of glass had entered the eye in the neighborhood of the corneal limbus below, involving the cornea and sclera, the iris had prolapsed and had been excised at the hospital, a portion of the prolapse had remained in the wound, a long siege of uveal inflammation had ensued, and this, in turn, followed by repeated attacks of sympathetic irritation for eight years. At the expiration of this time a severe blow had been received on the eyeball, followed immediately by a recurrence of the old uveitis, and three and a half weeks later by a typical attack of sympathetic uveitis in the other eye, the latter having appeared without any previous symptoms of irritation.

Treatment.—The offending eye was at once enucleated, atropin instilled in the right eye, and the patient given mercurial inunctions and potassium iodid to the point of tolerance. In spite of this, vision became rapidly worse. Subconjunctival injections of cyanid of mercury and pilocarpin sweats were now employed, but also without appreciable effect. Vision was now only 1/45 of normal. Salicylate of sodium in 20-grain doses four times a day was now ordered, and as no improvement was noted after four days' use, the dose was increased to 30 grains every three hours, or 150 grains during the twenty-four hours.

Result.—Within a week after beginning this amount the vitreous began to clear and the aqueous to become less turbid. The patient continued this amount daily for three weeks, the vision improving gradually all the time, and after this for four days only in each week. At the expiration of two months from the time of beginning the administration of the salicylate of sodium, the cornea was clear, except a slight stippling in the lower part; a few minute spots of opacity remained on the anterior lens capsule, the pupil was somewhat more sluggish than normal, the vitreous was slightly hazy, the margin of the optic nerve was decidedly veiled, and vision equaled 6/9. For some weeks afterward the patient continued to take 150 grains of the drug one day in each week, and there had not been any relapse in a year and a half. Since this time the patient has not been seen.

---

*Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

CASE 2.—W. B., a boy aged 8 years, on July 3, 1903, exploded a dynamite cartridge which he had found around some quarries, several pieces of the shell striking him in the face and eyes. He was at once seen by a physician, who ordered some cleansing lotion. On July 6, three days later, he was brought to the Jefferson Medical College Hospital.

Examination.—An examination showed numerous cuts and burns on both sides of face and eyelids, a few pieces of shell being buried beneath the skin surface. In the right eye the ocular conjunctiva was somewhat chemotic, the anterior chamber entirely filled with blood and 3 mm. down and in from the corneal limbus, directly through the ciliary body, was a circular opening 2 mm. in diameter, through which a small prolapse of the ciliary body and choroid protruded. Tension was —2, and vision equaled the counting of fingers at 3 feet. In the left eye, 4 mm. down and out from the corneal limbus, directly through the ciliary body, was a circular opening 1 mm. in diameter. The cornea and aqueous were clear, the vitreous was very slightly hazy, down and in, but the fundus was normal in all respects. Atropin was instilled, and a later examination through the dilated pupil revealed two small pieces of brass, which could be seen not only with the ophthalmoscope, but by means of oblique illumination. One of the pieces was located just behind the lens, near the lower margin, and to the left of a vertical axis; the other, somewhat deeper in the vitreous, to the right of and somewhat below the optic axis. Both pieces were small, gave the bright reflex of brass, and were slightly mobile in the vitreous immediately surrounding them, the latter being the only portion of the vitreous that presented any haziness. The tension was —1, and vision equaled 15/LXXX. The prolapsed portion of iris and choroid in the right eye was excised, the wound cauterized, atropin instilled, the constant application of cold compresses employed, and mercury administered internally.

A skiagraphic examination of the right eye was now made, and showed one large and possibly two very small doubtful shadows. We were, therefore, confronted with a most difficult problem. Both eyes contained foreign bodies, both had useful vision, and the right had suffered from a prolapse of the uvea, which had been excised. Should we, therefore, enucleate the right eye (by far the worse) in an effort to prevent sympathetic trouble in the left, or should we permit it to remain and watch for symptoms, inasmuch as the left eye also contained two foreign bodies? Dr. Howard F. Hansell, in whose service at the hospital the patient was seen, very kindly examined the patient with me, and agreed that the latter was the better plan to be pursued.

On July 27, three weeks from the time of admission to the hospital, the patient was discharged with instructions to return to the dispensary every other day for examination. At this time the right eye was still slightly red, but not painful. The anterior chamber was free from blood, but no view of the fundus could be obtained. Tension was normal. In the left, which was perfectly white and quiet, a slight cloudiness of the vitreous was noted in the immediate neighborhood of the foreign bodies (less than at the time of admission), but otherwise the vitreous was clear and the fundus normal, vision equaling 15/XX. On August 3, a week later, the patient was brought to the dispensary for the first time since being discharged. Examination showed a distinct optic neuritis in the left eye, with very minute deposits on the posterior corneal layer and on the anterior lens capsule. The vision was not so good as it was a week before, there was some dread of light, the eyeball was slightly congested, and the right eye also appeared more red and tender than when he had left the hospital.

Treatment.—It was believed that we were in the beginning of an attack of sympathetic ophthalmia, so the patient was again admitted to the house, the right eye enucleated, and the administration of mercurial inunctions and iodid of potassium begun at once. The eye had been under the influence of a mydriatic, and hot fomentations had been employed since leaving the hospital. On the following day the nerve was much swollen, the vitreous seemed to be filled with powder-like opacities, and there were many more spots on the cornea and lens capsule. On the latter the spots were arranged in a circle just within the border of the moderately dilated pupil. Vision was now 15/C, and in a few days more equaled only the counting of fingers at a few feet. No details of the fundus could be determined. As the eye had been growing rapidly worse under the use of mercury and the iodid, the patient was now ordered 80 grains of salicylate of sodium in the twenty-four hours, which was increased to 100 grains in a few days. Except for some dyspnea, this dose produced no disturbance, and in ten days' time the vitreous became sufficiently clear to permit a vessel to be seen here and there. This dose of salicylate was continued daily for about three weeks, the vision gradually improving as the vitreous cleared and the spots on the cornea and lens disappeared, at the end of which he was discharged from the hospital with a perfectly quiet eye and visual acuity of 15/L. The two pieces of brass could now be distinctly seen, and occupied relatively the same positions that they did at the time of the first examination. The salicylate was discontinued, but on the fourth day after leaving the hospital, the patient returned with a congested tender eyeball, a more hazy vitreous and vision again reduced. Within a week after resuming the use of the salicylate, the congestion disappeared, and the vitreous assumed the condition it had at the time of the patient's discharge; still somewhat hazy, but with vision equaling 15/L, and a subsidence of the neuritis. Between this time and January 12, a period of about four months, the administration of the drug was discontinued six times, and on each occasion the eye became worse, and immediately regained its former condition on resuming the use of the remedy. Toward the end of this period, the length of time the eye remained free from trouble when the salicylate was not being employed gradually increased, the last being of three weeks' duration. During one of the interims when salicylate was not being employed, pilocarpin sweats were tried, but without any appreciable effect. The remedy was now given in full doses on four days of each week for six weeks, and then one day of each week for a month, when it was discontinued.

Result.—Since this time there has been no recurrence. The vitreous is still somewhat hazy and there are some deposits on the cornea and lens capsule, but the neuritis has entirely subsided and the patient has a quiet eye with useful vision of 6/12. Whether further attacks will recur subsequently, or whether the pieces of brass will in course of time produce some intraocular reaction, it is impossible to say.[1]

Macroscopic Examination of Both Eyes.—When the eye of Case 1 was opened, a piece of glass was found which had broken loose partially from an extensive mass of exudate in the ciliary region, the latter extending forward to the original point of entrance. I regret that no inoculations of culture media were made from the end of the optic nerve at the time of enucleation, but, unfortunately, no facilities were at hand for doing so.

On opening the eye of Case 2, three pieces of brass were located; a very small piece in the cornea, another minute particle in the tissues surrounding the optic nerve which had probably been carried there at the time of bisecting the globe, and a third and large piece in the choroid just posterior to the equator of the eyeball. This last piece had entered through the ciliary body, and had ploughed a furrow from the point of entrance to its resting place, through which the sclera was distinctly visible.

---

[1] Six months after presenting this paper there had been no further recurrence and the visual acuity was maintained.

Microscopic Findings in Both Eyes.—Microscopically, each eye showed a dense infiltration with leucocytes of iris, ciliary body and choroid, all of these membranes being greatly thickened. The pupil in Case 2 was closed with exudate, between which and the iris it was almost impossible to differentiate. The retinæ were slightly infiltrated, very edematous and thickened, much more marked in the posterior portion of the eye. All the penetrating vessels and nerves showed marked increase in leucocytes and connective tissue cells. The vitreous was also filled with leucocytes. The optic nerve of Case 2 showed a slight degree of papillitis, and the central vessel, as far back as sections were obtained, also showed evidence of inflammation by the increase of leucocytes. Some leucocytes were also noted in the intervaginal space.

Cross-sections of the optic nerve of Case 2 showed a most peculiar condition. Scattered throughout the sections were areas of degenerated fibers, most marked in the immediate neighborhood of the trabeculæ, but occasionally involving a complete bundle of fibers, and more rarely two or three adjoining bundles. In none of the sections was the degeneration found in the center of a bundle alone. It always seemed to begin at the trabecula and pass inward toward the center. In some of the sections the degenerative areas were most marked in the immediate neighborhood of the central vessels, and from these similar areas spread outward in different directions. These sections were examined by Dr. William G. Spiller, professor of neuropathology in the University of Pennsylvania, who believed that the condition was due to the passage of toxins along the trabeculæ of the nerve, as is seen in nervous tissue elsewhere in the body.

As soon as the optic nerve of Case 2 was severed and the eyeball rotated forward, inoculations of culture media were made from the severed end and sent to the laboratory of the Jefferson Medical College for a report. In forty-eight hours a culture developed, which was composed of cocci, and which, morphologically, tinctorially and biologically, corresponded to the *Staphylococcus pyogenes aureus*. This same micro-organism has been found inside of some of the blood vessels adjoining the optic nerve.

REMARKS.

In these two cases there is a wide difference in the time of appearance of the disease in the sympathizing eye. In the first case the inflammation did not become manifest until eight years after the injury, the piece of glass remaining in the eye during this period. It seems quite plausible, however, that the blow on the eye, which was received three and a half weeks before the onset of the affection, disturbed the position of the piece of glass, that had remained quiescent for so long probably because it had been encysted, and brought about a recurrence of the old uveitis, which was followed by the sympathetic attack in the other eye. In the second case, the inflammation appeared at the end of the fourth week. It may be urged by some that the piece of brass in the affected eye may have had something to do with the subsequent symptoms as they presented themselves, but, beyond a slight localized inflammation of the vitreous immediately surrounding the foreign bodies, I do not believe that this was true. It is not likely that foreign bodies in the vitreous would give rise to the chain of symptoms above described, exactly simulating those of sympathetic ophthalmia, continuing the course of the latter disease and finally terminating in recovery. Besides, it is a well-known fact that pieces of brass may lie dormant in the vitreous indefinitely, and that when they do set up inflammatory reaction the symptoms are not like those of sympathetic uveitis.

The onset of the disease in both cases without any premonitory symptoms agrees with the experience of others on this point. In the first case there had been repeated attacks of irritation for several years, but when the typical sympathetic inflammation manifested itself, it did so suddenly, with no other symptoms observable to the patient than rapidly failing vision. This would indicate, as pointed out by Gifford, that the vision should be carefully ascertained each day, as its failure would seem to be among the first noticeable signs of the advent of the disease.

The value of the administration of large doses of salicylate of sodium demands especial mention, and corroborates the experience of Gifford and others who have given the remedy a trial. In both cases, mercurial inunctions, the iodids, subconjunctival injections and pilocarpin sweats not only failed to ameliorate, but even to check the progress of the affection. In the first case, the symptoms promptly abated after the administration of the remedy was commenced, and in the second case the symptoms were not only abated, but rapidly returned on each occasion that the use of the drug was discontinued during a period of several months. My experience fully concurs with that of Gifford, that the drug must be administered in large doses to be of value, and, should I have under my care a patient whose stomach would not tolerate such doses, I would attempt, as he has suggested, its administration by rectum, or perhaps by inunction. Should there be any heart or nephritic disease, smaller doses must be given at first and the effect carefully noted, but it is my belief that these small doses will not be found sufficient to control the sympathetic affection. The addition of a teaspoonful of brandy, as suggested by Gifford, or of a few drops of the tincture of nux vomica, or aromatic spirits of ammonia, to each dose has appeared of value, not only in increasing the tolerance of the stomach to the drug, but in relieving, to some extent, the more or less depressant effect on the heart.

As to the theory of the production of the affection, these cases, unfortunately, like so many others, do not throw much light on the subject. Both cases would seem to indicate that the disease is an infectious process arising in the primarily affected eye, and by some means of exit leaving that eye to obtain a resting place and a good breeding ground in the other. As to the manner of exit, the first case gives no information; but it seems to me that in the second case the condition of the optic nerve and the central vessels would indicate that at least some of the infectious material passed outward in this way.

THE GENESIS OF SYMPATHETIC OPHTHALMITIS.*

SAMUEL THEOBALD, M.D.

Clinical Professor of Ophthalmology and Otology, Johns Hopkins University; Ophthalmic and Aural Surgeon to the Johns Hopkins Hospital and to the Baltimore Eye, Ear and Throat Charity Hospital.

BALTIMORE.

Thirty years ago, it is safe to say, there was but one view held as to the genesis of sympathetic ophthalmitis. The doctrine of Mackenzie that the optic nerve played the chief rôle in the transference of the inflammation from the exciting to the sympathizing eye, had been universally abandoned, and the view that the pathologic changes in the secondarily affected eye were the product of an *influence—an influence* of a reflex character—transmitted to it through the ciliary nerves, was as universally accepted. This view, which had been suggested by Mackenzie as an alternative but improbable explanation of the phenomena of sympathetic inflammation, and had been advanced previously by Tavignol, in 1845, was first brought prominently forward by Heinrich Müller, who published his conclusions —based on pathologico-anatomic observations—in 1858. His theory gained converts rapidly, and among those who accepted it, and who soon became its ardent advocates, were von Graefe, Donders, Arlt and Bowman. To them it seemed all sufficient, and through their labors it was fortified and strengthened. Numerous pathologic observations by Donders and many other competent observers, based on careful dissections of eyes enucleated because of sympathetic irritation or inflammation of the fellow-eye, and innumerable clinical facts were brought forward to sustain it, and, before long, it seemed if there was one question in ophthalmology settled beyond peradventure, that question was the genesis of sympathetic ophthalmitis. But time works many changes, and now, after the lapse of thirty years, it may be truthfully said, if there is one question in ophthalmology, seemingly, farthest from determination, and as to which least definite views are held, that question is the genesis of sympathetic ophthalmitis.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

When pathology declared that an irritation transmitted through sensory nerves, or even through nerves containing sympathetic as well as sensory fibers, could not produce inflammation—could, at most, but cause vasomotor paralysis—and when it further told us that an inflammation such as occurs in a sympathetically affected eye must, almost of necessity, be the product, direct or indirect, of bacterial action, "something," to use a slang phrase, "had to give way," and that something, so far, at all events, as those were concerned who felt it incumbent on them to accept without question Pathology's dicta, was the doctrine of Heinrich Müller, of von Graefe, Donders and Bowman that sympathetic ophthalmitis was a neuropathic affection, and that the influence which brought it about was transmitted through the ciliary nerves.

And now it became the duty of the ophthalmologists who were pathologists as well, to construct a new theory of the origin of sympathetic ophthalmitis, which should take the place of the one that had been dethroned so unceremoniously. The first to undertake this task was Dr. Adolf Alt,[1] who, in a paper "On the Anatomical Causes and the Nature of Sympathetic Ophthalmia," argued in favor of the older view—the doctrine of Mackenzie—that the optic nerve furnishes the chief route by which the inflammation proceeds from the exciting to the sympathizing eye. His paper, which showed painstaking and laborious research, gave an account of the pathologic changes found in 112 eyes enucleated because of sympathetic disease of the fellow-eye; and his conclusion, in favor of the optic-nerve theory, was based mainly on the large percentage of pathologic changes in the retina and optic nerve, and the small percentage of changes in the ciliary nerves, which these eyes exhibited. His views attracted wide attention and gained many adherents. When, however, it was pointed out[2] that the "changes" in the retina and optic nerve, to which he attached so much significance, consisted in a large measure of detachment of the former and atrophy of the latter[3]—retinitis and neuritis being conspicuous by the infrequency of their mention—and, further, that in the whole series of 112 eyes there was but one instance (this single exception being a doubtful one, and probably due simply to the scantiness of the information supplied regarding it) in which it was not manifest that the uveal tract, as well as the optic nerve and retina, was the seat of pathologic changes, the inconclusive character of the evidence which he had brought forward, and its irrelevancy so far as the question of the etiology of sympathetic inflammation was concerned, became apparent; and, before long, his views received less consideration and his data were less frequently cited.

The next doctrine advanced, and the one still commonly in vogue, was that sympathetic ophthalmitis was a septic affection, and that it was caused by a hypothetical micro-organism, which traveled from the exciting to the sympathizing eye along the lymph spaces of the optic nerve. Leber and Snellen, in 1881, were among the first to advocate this view, a variant of which was suggested by Berlin, who thought it more probable that the infection of the second eye occurred through the general circulation, and, to account for the absence of pathologic manifestations in other organs, assumed for the hypothetical micro-organism a hypothetical affinity for the ocular tissues.

Schmidt-Rimpler later, in 1892, proposed a modification of Berlin's theory—which has the merit, it seems to me, of being less radically hypothetical—that the micro-organism, after reaching the second eye by way of the general circulation, attacked its tissues, rather than those of other organs, because they had been rendered less resistant in consequence of the congestion produced in them by the vasomotor reflex from the exciting eye, a view which had previously (1887) been advanced by Gifford.[4] The latest modification—for the rather fascinating cytotoxin idea of Brown Pusey[5] can not be classed under this head—of the germ theory, also first suggested by Gifford, but more formally put forth by Bellarminoff and Selenkowsky, is that it is the toxins produced by the bacteria in the exciting eye that pass over to the fellow-eye and cause the mischief with which we are all so familiar.

The experiments of Deutschmann, in which he endeavored to produce sympathetic ophthalmitis in rabbits by introducing into the eye a pyogenic micro-organism, attracted wide attention and, for a time, were regarded as affording strong evidence in favor of the germ theory of the disease; but, as is well known, Gifford, Randolph and others who repeated his experiments failed absolutely to confirm his results. Apart from this lack of confirmation, however, the result which he claimed to have obtained—an infection of the second eye as part of a general systemic infection, of which the rabbits soon died—was so wholly unlike true sympathetic ophthalmitis as we know it in man, that even had his experiments been confirmed at the hands of other investigators they really would have thrown little or no light on the etiology of the disease.

It is hardly necessary to point out that, although nearly a quarter of a century has elapsed since the germ theory of sympathetic ophthalmitis was first propounded, no positive evidence has been adduced to sustain it, and that to-day it must still be regarded as a mere hypothesis, resting on a far from substantial basis. As Gifford, one of its ablest supporters, has well expressed it[6]: "The most ardent advocates of the germ theory of the disease admit, on their part, that the nature of the germ which causes the disease, and the path which it takes in reaching the second eye, are as yet unknown. . . ." Not only is this true, but it is also true that only in rare instances have micro-organisms of any kind been found in eyes enucleated because of sympathetic disease of the fellow-eye.

[2] "Some Recent Theories Regarding the Pathogeny of Sympathetic Ophthalmia, Viewed from a Macroscopic Standpoint." S. Theobald, Archives of Ophthal., vol. xiii, No. 1.

[3] H. Müller had already expressed the view that an atrophied optic nerve "could hardly have the power of transmitting an irritation or any other process from the eye." Indeed, one of the arguments which he adduced in favor of his theory was that the ciliary nerves are less liable than the optic nerve to undergo atrophy.

[4] Trans. International Med. Congress, 1887, vol. iii, p. 769.

[5] Archives of Ophthal., vol. xxxii, No. 4, 1903.

But, beside this lack of positive evidence in favor of the view that sympathetic ophthalmitis is caused by a specific micro-organism, there are many clinical and pathologic facts which seem to weigh strongly against this doctrine. Among them may be mentioned the beginning of sympathetic inflammation so much oftener in the anterior than in the posterior structures of the eye; the extremely variable period of incubation of the disease; notwithstanding Alt's data to the contrary, its much more frequent occurrence as a result of injuries and disease of the iris and ciliary body than of affections of the retina and optic nerve; its development in consequence of non-penetrating wounds of the eye—burns of the cornea, for example[7]—and of loss of the eye from herpes zoster ophthalmicus (Noyes),[8] from non-traumatic iridocyclitis, etc.; and the well-established fact that enucleation of the exciting eye not very infrequently stops the progress of the disease in the sympathizing eye, a result which it would be difficult to explain if the mischief in this eye were really due to a micro-organism that had reached it, either by way of the lymph spaces of the optic nerves or through the general circulation.[9]

On the other hand, when we turn from the germ theory of sympathetic ophthalmitis to the discredited ciliary nerve theory—the theory which was so satisfying to those astute observers and logical reasoners who deserve to be, and always will be, looked back to as the founders of modern scientific ophthalmology—we no longer find discordance, but the completest harmony, it seems to me, between theory and observed facts. The absence of bacteria in the exciting eye; the variable period of incubation; the significance of disease and injuries involving the iris and ciliary body—those structures so richly supplied with sensory nerves, and inflammation of which almost always means intense suffering—the site at which the inflammation commonly begins in the sympathizing eye; the occurrence of sympathetic disease in consequence of non-penetrating injuries of the cornea, which, however, have given rise to painful and protracted keratitis; the arrest or favorable modification of the disease from enucleation of the primarily affected eye; its occasional development after enucleation of the exciting eye;[10] the long-continued existence of sympathetic irritation in some cases without the development of actual inflammation, and in others the occurrence of inflammation with but little precedent irritation—all these phenomena become explicable, are, indeed, but what the theory would lead us to expect.

It has been contended that if the ciliary nerve theory were true, sympathetic irritation should always lead to the development of sympathetic inflammation. Doubtless, if the opportunity were afforded, this is what, in the great majority of cases, would, sooner or later, happen; but as an argument against the theory this contention is as absurd as to insist that blepharitis marginalis can not be caused by strain of accommodation, because it is not present in every case of ametropia. As stated in my paper to which reference has already been made:

> That in some instances inflammatory changes occur in the second eye without sympathetic irritation, and that in others sympathetic irritation of the most marked character exists for a long time without inflammation, does not militate against the view that both of these conditions are dependent on a reflex influence transmitted through the ciliary nerves, as some would have us believe. In the first place, the ciliary nerves contain sympathetic as well as sensory fibers, and it is probable that the former have most to do with trophic changes, the latter with disturbances of sensation. In the second place, in view of the astonishing difference in the degree of pain inflicted in different persons by the same amount of violence done to the nerves, we are justified in assuming that in the eye, as well as in other parts of the body, these two kinds of fibers do not always exist in the same relative proportion, or, at least, that, in different individuals, sometimes the influence of one set, and sometimes the influence of the other, may predominate. Admitting this much, we shall have no difficulty in comprehending why a given lesion of the ciliary body, for example, should give rise, in one instance, to pronounced sympathetic irritation unaccompanied by structural changes; and, in another, to trophic changes in the sympathizing eye with little or no accompanying irritation.

The fact that, in some instances, sympathetic inflammation begins at the posterior pole of the eye, as a neuroretinitis or choroidoretinitis, has been regarded as being distinctly favorable to the theory that the disease is transmitted by way of the optic nerve or its lymph spaces; but, as I pointed out in my previous paper, this is only what the ciliary nerve doctrine would lead us to anticipate, since it is here, about the optic nerve, that the short ciliary nerves enter the eyeball, and the neighboring choroid coat—between the blood vessels of which and those of the papilla there is intimate anastomosis—is especially rich in its ciliary nerve supply.

Even the most uncompromising opponents of the doctrine that sympathetic *inflammation* is caused by a reflex irritation transmitted through the ciliary nerves, admit that the photophobia, lachrymation, incapacity for work, and, most significant of all, the vascular congestion, the vasomotor paralysis, which are the characteristic features of sympathetic *irritation*, are produced in this way; and the pathologists, who certainly can not claim that they have ever been able to reproduce experimentally a condition even approximately identical with that which exists when an eye sympathizes with its injured fellow, allow, on their part, that when the reflex congestion caused by irritation of sensory nerves lasts for a considerable time, as it does in a sympathetically affected eye, it places the cells of the part in a condition of instability, lowers the vitality of the capillary walls, and offers facilities for the emigration of leucocytes, so that on slight provocation inflammation may be precipitated. In a word, they admit that, solely through the influence of the ciliary nerves, we may have in the sympathizing eye a condition which is just short of actual inflammation.

---

[6] Posey and Wright's Diseases of the Eye, Nose, Throat and Ear, p. 391.

[7] I have met with one such case, where a severe and protracted keratitis was produced by the accidental instillation into the eye of aqua ammoniæ, and other cases have been observed.

[8] Trans. Am. Ophthal. Soc., 1873, p. 71.

[9] It must be admitted that this difficulty would not be so great as to either the bacterial toxin or the cytotoxin theory.

[10] As to this phenomenon, I remarked in the paper already referred to: "It is quite unnecessary to adopt the progressive optic neuritis hypothesis in order to account for the origin of sympathetic inflammation . . . . after enucleation of the exciting eye; for it is altogether probable that the disturbances in nutrition in the second eye are preceded by and are dependent on molecular alterations (perhaps a slight myelitis as suggested by Brecht) in the vasomotor or 'trophic' centers, and that these again are secondary to alterations of similar character in the gasserian and ophthalmic ganglia; so that we need only suppose that in exceptional instances these changes have progressed so far as not to be arrested by the enucleation of the eye, to obtain an entirely satisfactory explanation of the etiology of these anomalous cases."

At last, however, it would seem, the pathologists are willing to concede even more than this; to concede, in fact—if I rightly interpret the conclusions reached by Head and Campbell as a result of their carefully conducted investigations concerning the pathology of herpes zoster[11]—all that the advocates of the ciliary nerve theory of sympathetic ophthalmitis ever have claimed—that, without the intervention of bacteria or their products, inflammation may be set up in a distant part in consequence of an irritation of sensory nerves in relation with this part.

Among other conclusions drawn from their study of herpes zoster by Head and Campbell—and it should be remarked that their results have been widely accepted, and by pathologists of the highest distinction—are the following:

The eruption of herpes zoster is produced not "by disturbance of special trophic nerves, but by intense irritation of cells in the ganglion which normally subserve the function of pain. . . ."

There is no evidence that bacteria take part either in the ganglion lesion, which they describe as "an acute interstitial inflammation accompanied by necrosis of the ganglion cells," or in the secondary skin lesion, the contents of the vesicles whenever examined having been found sterile, or in the consequent inflammation of the lymphatic glands. "Thus," they comment as to the last-mentioned observation, "we are brought face to face with the curious fact that a collection of intensely inflamed vesicles containing a sterile fluid can be associated with enlargement of the lymphatic glands. Moreover, these glands have all the appearance of being inflamed. and yet show no sign of bacterial invasion."

Do not these concessions which, as yet, I believe, have not been controverted, dispose of the only serious objection which has ever been urged against the ciliary nerve theory of sympathetic ophthalmitis? If an "intense irritation" of ganglion cells "which normally subserve the function of pain" can produce, without bacterial or traumatic intervention, inflammatory changes in the skin areas supplied by the sensory nerves emanating from these cells, is there any reason why the "intense irritation" proceeding from an injured or diseased eye to its fellow may not, in like manner, produce inflammatory changes in it? Or, to put it more definitely, are we not warranted, reversing the sequence of events as described by Head and Campbell, in assuming that intense and long-continued irritation of sensory nerves, such as we have in a seriously injured and chronically inflamed eye. may cause inflammation in the ganglion cells with which these nerves are in relation. and that this. in turn, may bring about the inflammatory changes in the sympathizing eye? And this, as a glance at my previous paper will show,[2] is precisely the doctrine which I advocated twenty years ago, and which has always seemed to me more satisfying than any other that has yet been advanced in explanation of the genesis of sympathetic ophthalmitis.

I may add, in conclusion, that I have long held that sympathetic inflammation of the eye and herpes zoster ophthalmicus are related affections.[2] Indeed, in my lectures in the Johns Hopkins Medical School (and I have expressed the same views in published writings[12]), it has been my habit to lay stress on a group of diseases of the cornea and of the iris, which, for lack of a better name, I have spoken of as "trophic nerve" inflammations. In this group I have placed, besides sympathetic ophthalmitis and herpes zoster ophthalmicus, the keratitis which follows malarial fever, certain intractable forms of monocular keratitis and irido-keratitis, usually attended by anesthesia of the cornea, and of monocular plastic irido-choroiditis and, with less assurance, serious iritis or uveitis, which also, as is well known, is almost always limited to one eye.

These several "trophic nerve" affections which, it will be observed, are invariably unilateral, I have looked on as due to a common cause—disease of one or more of the ganglia in relation with the fifth nerve, oftenest, probably, of the ophthalmic ganglion, less often of the gasserian ganglion or of the central ganglia themselves. As the investigations of Head and Campbell seem to lend support to this teaching—which I realized was not in accord with the prevalent views regarding the genesis of inflammation—as well as to the ciliary nerve theory of sympathetic ophthalmitis for which I have so long contended, they have afforded me no little satisfaction.

OPERATIVE PROCEDURE ON THE EXCITING AND THE SYMPATHIZING EYE IN CASES OF SYMPATHETIC OPHTHALMIA.*

JOHN E. WEEKS, M.D.
NEW YORK.

The object of this paper is to mention certain classes of conditions which are met with in eyes that produce, and in those that are affected by, sympathetic ophthalmia, as represented by the cases narrated, and to discuss briefly the treatment which seems to me to be indicated, trusting that the subject may meet with a full expression of opinion by the members of the Section.

1. Cases in which the exciting eye still preserves vision, the sympathizing eye being in the early stage of sympathetic ophthalmia. The following is a report of a case in point:

CASE 1.—E. B., aged 43, was admitted to the New York Eye and Ear Infirmary, Jan. 23, 1904. About Nov. 13, 1903, a piece of brick flew into his left eye. Three days later he went to a hospital in Brooklyn and was operated on. He says "there was pus in the eye and an ulcer which perforated." After being in the hospital five weeks he was discharged cured.

Examination.—Left eye, V = fingers at 4 feet. Conjunctiva injected; large macula in lower half of cornea, almost completely covering the pupillary area; remaining portion of cornea quite clear; iris adherent to cornea by a number of filiform shreds at lower portion; pupil not responsive to the stimulus of light, anterior chamber fairly deep; no ciliary tenderness; tension normal. Right eye, V = 20/30 +; conjunctiva injected; cornea clear; pupil dilates fairly regularly under atropin; anterior chamber clear and deep; no ciliary tenderness; three or four filiform posterior synechiæ.

---

[11] Brain, vol. xxiii, Part 3, 1900, pp. 353-395.

[12] See article on "Iritis," contributed by me to the Reference Handbook of the Medical Sciences, first edition, vol. iv, p. 219, and second edition, vol. v, p. 218.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Diagnosis.—Sympathetic ophthalmia.

Treatment—Mixed treatment and salicylates internally; inunctions every second day; atropin. On account of the early stage of the sympathetic ophthalmia and the fairly good condition of the exciting eye, I thought it best not to remove that eye, as it might possibly eventually be the better of the two. Thinking that perhaps the anterior synechiæ existing in the exciting eye were instrumental in causing the sympathetic inflammation, I thought that an operation for the relief of the traction on the iris might favorably influence the inflammation of the sympathizing eye. I therefore performed iridectomy, using a keratome for making the incision and dividing the greater number of the anterior synechiæ with the point of the keratome. A large iridectomy was performed without accident. The eye healed kindly and quickly without inflammatory reaction, but the operative procedure had no appreciable effect on the course of the ophthalmia in the sympathizing eye, which was a relatively mild one, but which affected the entire vascular coat of the eye.

Result.—March 15, a little more than seven weeks after the beginning of treatment, the sympathizing eye is rapidly improving. The exciting eye shows but little evidence of inflammation and V = fingers at 5 feet. However, the coloboma following the iridectomy is partly filled in by plastic lymph.

I feel that the course pursued in the treatment of this case was perfectly justifiable, but, because of the tendency to closure of the coloboma with plastic exudation, which proceeded in this case without appreciable inflammatory reaction, I can not say that much was gained by the iridectomy. It is my opinion that the sympathetic inflammation would not have been more favorably influenced had the exciting eye been enucleated, and that all that we might reasonably expect has been accomplished in the treatment of the sympathizing eye. The condition of the latter will undoubtedly continue to improve.

2. Cases in which the sympathizing eye has become quiet, with almost complete posterior synechia, pupil occluded, vision perception of light, projection good, tension normal or slightly below normal, the exciting eye not a factor. To this class belong the following cases:

Case 2.—James C., aged 12, came under my observation in May, 1892. Three years previously he received an injury in the left eye, producing a wound through the ciliary region. Six months later sympathetic ophthalmia of the plastic variety occurred in the fellow eye. During treatment for the condition the exciting eye was enucleated.

Examination.—When the patient came under my observation the sympathizing eye was quiet, the pupil was blocked by a pseudomembrane, there was extensive posterior synechiæ, iris changed in color, slightly opaque and presenting some radial folds. Atropin had no effect on the pupil, except at one small point, where slight dilatation occurred. Tension was very little below normal. Vision equaled perception of light. Projection good. Since the eye was apparently quiet, I was of the opinion that a greater degree of vision might be obtained by performing iridectomy.

Treatment.—The patient was admitted to the New York Eye and Ear Infirmary and a broad iridectomy performed under general anesthesia. It was found that the pigment layer of the iris remained adherent to the capsule of the lens from the pupillary margin, two millimeters toward the equator of the lens; the lens appeared to be transparent. The wound closed readily, but within six weeks the coloboma was filled in with a pseudomembrane, its formation being accompanied by slight injection of the ciliary zone of the ocular conjunctiva, resulting vision being no better than before the operation. A second attempt to obtain a coloboma was made some months later without success.

Case 3.—Frank H., aged 42, thirty years ago was struck in the right eye with a ball, which evidently ruptured the globe, the injury occurring in the ciliary zone. At the present time the globe is shrunken, painless and sightless. Six months after the injury to the right eye, sympathetic ophthalmia affected the fellow eye. The sympathizing eye has been free from inflammation for many years.

Examination.—Globe of normal size; cornea clear; pupil occluded; complete posterior synechia; iris atrophic; anterior chamber about one-half normal depth; —T. ½; vision perception of light in all parts of the field; projection uncertain. The patient was admitted to the New York Eye and Ear Infirmary Oct. 6, 1902.

Treatment.—Thinking that it might be possible eventually to obtain a clear pupillary opening, I made a broad iridectomy upward and succeeded in removing the anterior layers of the iris only. The pigment layer remained adherent to the underlying tissues. The wound was then permitted to heal. Slight ciliary irritation followed the operation.

October 30, eye quiet; —T. ½; defect in iris somewhat narrowed by the deposition of plastic lymph. Jan. 3, 1903, patient was again admitted to the infirmary; tension of globe slightly below normal; eye free from inflammation. An attempt was now made to clear the pupillary area and the area of the coloboma of the opaque mass which occluded it. An incision through the cornea was made with a keratome and by means of a sharp cystotome, De Wecker's iris scissors and forceps, the pseudomembrane was removed and what remained of the lens (which was found to be shrunken and opaque) was expressed and removed by irrigation. A thin cyclitic membrane which stretched across the posterior surface of the lens capsule was recognized, but was not removed, as it was thought best to deal with it later.

Result.—The wound closed, but the healing process was accompanied by ciliary injection and some ciliary tenderness. The coloboma gradually filled with plastic exudate and the scar became slightly indrawn. Tension remained below normal and the vision did not become greater than perception of light He was discharged Jan. 24, 1903. At that time I did not think that there was any prospect of improvement in vision by subsequent operation. Although I have not seen the patient since his discharge from the infirmary, I have recently learned that his vision is the same.

3. Cases in which cataract has formed in the sympathizing eye as a result of sympathetic inflammation: posterior synechiæ; eye quiet; projection good; the exciting eye not a factor. A case in point is the following:

Case 4.—Charles S., aged 29, was admitted to the New York Eye and Ear Infirmary, Jan. 27, 1903. At the age of 12 he was injured in the left eye by the explosion of a firecracker. The eye became very much inflamed and the vision was reduced to perception of light. Five years later sympathetic ophthalmia of the right eye developed. Vision became reduced to perception of light. Six years after loss of vision in the sympathizing eye, an iridectomy was performed on this eye by Dr. Howe of Buffalo, in the hope of improving the vision, but without success.

Examination.—Right eye, conjunctiva normal. Cornea clear in its upper two-thirds. Slight opacity at both margins of the cornea just below the horizontal meridian, measuring 2 mm. in width and 2½ mm. in length—ribbon-shaped keratitis in the early stage of development. —T. The anterior chamber is about two-thirds the normal depth The iris is atrophic and adherent to the capsule of the lens throughout about two-thirds of its extent. Two or three radiating slits in the iris in addition to a small coloboma upward and outward. The pupillary area is occupied by a thickened mass of pseudomembrane. The lens presents a yellowish-white appearance and is of normal size. Perception of light good in all parts of the field of vision. Left eye, the conditions are similar to those in the right eye, except that they are a little more pronounced. Vision equals perception of light, but the projection is faulty, particularly in the lower nasal portion of the field.

Treatment.—As the eye had been quiet for some years and the projection was good, I told the patient that there was a possibility of improving his vision by removing the lens, which was done on the afternoon of January 27. An incision was made with a Graefe knife at the limbus, making a small conjunctival flap. With a small, sharp cystotome, the capsule of the lens close to the margin of the iris below was cut through and the iris liberated in its upper half. A broad iridectomy was then made, after which capsule forceps were introduced and a large portion of the anterior capsule, including the pseudomembrane, drawn out. The lens, which was rather hard and presented calcareous deposits in its cortical layers, was then removed. It was somewhat adherent to the remaining capsule and its expulsion was difficult. However, it came away fairly satisfactorily, and irrigation of the anterior chamber with normal salt solution sufficed to remove almost every particle of lens substance without loss of vitreous.

Result.—Progress was favorable and without untoward symptoms until the third day after the operation, when a small hyphema was present, the blood being bright red in color, apparently coming from the iris. Four days after the operation the patient was able to count fingers at one or two feet.

February 26, V. = fingers at four feet, eye quiet. The coloboma is not so large as it was immediately after the operation. Aside from a slight opacification of the posterior capsule of the lens, there is no evidence of the formation of a cicatricial pupillary membrane. A faint reflex from the fundus can be obtained, but the vitreous humor does not appear to be perfectly transparent. —T. ½.

Six weeks after the first operation the posterior capsule was divided vertically by means of a narrow Graefe knife and a large, clear opening obtained, which has remained.

Feb. 27, 1904, more than one year after the operation, vision with a correction lens equals 20/40; tension a very little below normal. Patient reads ordinary type with facility.

An interesting feature in this case is the formation of "ribbon-shaped" keratitis, which develops only in eyes that are degenerating. Since the operations were performed, the keratitis has ceased to develop in the seeing eye, and the whole aspect of the eye has changed for the better.

4. Cases in which, with occluded pupil, total posterior synechia exists in the sympathizing eye. The tension is plus and increasing (secondary glaucoma); projection still good; the inflammatory process in a subacute stage, the exciting eye not now a factor. The problem is how to retain vision in such an eye.

CASE 5.—David J., aged 15, came to my office April 10, 1903. Eleven weeks before he had had an operation for the removal of cataract from the left eye, which was followed by iridocyclitis.

Examination.—When seen the left eyeball was soft and tender on pressure; the iris was caught in the angles of the wound, and the cicatrix corresponding with the incision for the removal of the lens was indrawn. V = perception of light. Right eye, incipient cataract, transient increase of tension. May 30: very slight iritis; early stage of sympathetic ophthalmia.

Treatment.—Removal of the exciting eye advised and strongly urged. The patient disappeared, but returned June 29 and consented to have the exciting eye removed, which was done at once. The sympathetic ophthalmia, which was then well advanced, was favorably influenced by removal of the exciting eye.

September 1, two months after the exciting eye was removed, the condition of the sympathizing eye was as follows: Complete posterior synechia; tension plus and increasing; ocular conjunctiva slightly injected; anterior chamber shallow; pupil blocked by pseudomembrane; V = perception of light; projection fairly good; field perhaps a little narrowed.

Here was an eye in the last stage of sympathetic ophthalmia, with secondary glaucoma, about to become blind by increase in pressure. The anterior segment of the globe had apparently suffered most from the sympathetic ophthalmia. The question to decide was whether we should endeavor to save the vision by operative procedure for the purpose of relieving the tension. If operation was decided on, what operation should be performed?

A broad iridectomy was done and the lens removed.

Result.—The inflammatory process affecting the eye was not accelerated, but did not abate. The coloboma was slowly filled with plastic exudation and, by subsequent contraction of the exudation, was abolished. The scar became slightly sunken. Tension minus. Vision equaled perception of light. Eye slightly painful.

May 28, 1904, globe atrophic; no perception of light.

In view of what has preceded, it must be admitted that the tendency to plastic exudation in the exciting and in the sympathizing eye in sympathetic ophthalmia is very great, even after the actual inflammatory stage has passed; that it is sufficient to destroy the immediate results of operations on the iris if any degree of inflammation still exists. If increased tension does not exist, operation is not justifiable until all traces of inflammation have passed and even then the result will be uncertain.

If tension is increased and blindness sure to follow if this is not relieved, operation, however small the chances for success, should, in my opinion, be undertaken.

DISCUSSION

ON PAPERS OF DRS. VEASEY, THEOBALD AND WEEKS.

DR. LEARTUS CONNOR, Detroit, said that, while Dr. Theobald states that the ciliary route is the mode of communication from one eye to the other, other observers emphasize the other routes, such as the lymphatics, optic nerve, and blood vessels. Dr. Connor believes that probably all these routes are involved in many, if not all, of these cases. The ciliary theory assumes that it is a local irritation and in every case of sympathetic ophthalmia the ciliary body is involved. In that body there are not only ciliary nerves, blood vessels, and lymphatics, but also muscular tissue. It may be that changes in muscular metabolism will explain why, after ten or twenty years, other obscure phenomena of sympathetic ophthalmia may occur. Unfortunately, the evidence that bacteria are the sole cause is not conclusive. It may be that finer methods of research will throw more light on the subject. Study of toxins teaches that, directly or indirectly, they may produce the trouble. The history of sympathetic ophthalmia illustrates the evolution of great discoveries in medicine.

DR. C. H. WILLIAMS, Boston, stated that, whatever may be the cause of the condition, physicians are most concerned with the treatment. He referred to the case of a woman, about 30, who had severe uveitis in one eye, which later developed in the other, apparently from sympathetic action. It went on so badly in that eye that it had to be enucleated. Last fall she had a return of this uveitis in the first eye, and Dr. Williams tried everything that had been recommended—salicylates up to 1 gr. to the pound of weight, mercurials and all that. She had 4/10 vision when he first saw her, which gradually went down to fingers at fifteen feet. His brother, Dr. Francis Williams, had just returned from Paris with some pure radium bromid and they tried the radiations from that. They used the pure radium bromid, at first three times a week, then twice and then once, held within a quarter of an inch of the eye in one-minute periods with a rest between. The result was that the ciliary congestion lessened and the interstitial keratitis subsided and she now has a vision of 5/10 in that eye. One case does not show very much, but it at least illustrates this point: An eye can be exposed to the radiations of pure radium bromid without doing any harm, provided it is done with care.

DR. G. C. SAVAGE, Nashville, stated that he does not believe in the ciliary irritation theory. He has had two cases occur after the exciting eye had been enucleated. If that theory were true it would be correct to tell patients that when the exciting eye is removed they are in no danger whatever of *sympathetic ophthalmia, for the moment* the eye is removed the danger is past. He does not believe that it is a toxin either, and yet he has not any very good reason for that belief. He believes that the migration theory is the true theory, and he will continue to believe it until some one demonstrates that it is not correct. If it is the correct theory, how long does it take the germs to travel through the lymph channels from one eye to the other? When he first accepted the germ theory he was taught to believe it would take about six weeks. In the last few years he had a case that occurred four weeks after the original lesion, so that if he holds to the germ theory he must believe that some germs can travel this course in from three to four weeks. Now, the exciting eye, if it is useless, should be removed, the sooner the better; *and its removal should never be delayed beyond from four* to six weeks without the patient taking the responsibility, because a delay beyond that time may be attended by migration of the germs and loss of the other eye. If the patient will not consent, let him take the responsibility; there will not be a moment when he will not be in danger. Then, too, he never says to a patient, or to his friends, that when the exciting eye is removed the other eye is absolutely free from danger. Dr. Savage has had two well-marked cases of sympathetic ophthalmia occur after enucleation of the exciting eye. He believes that at any time within from four to six weeks after enucleation of the exciting eye sympathetic trouble in the other eye may occur, the germs having commenced their journey before the enucleation. Later than this he would expect no sympathetic trouble.

Dr. Edward Jackson, Denver, said that the suggestion made in the *Archives of Ophthalmology* a year ago by Brown Pusey should not be passed over without something more than mere mention. The suggestion was based on the experiment of producing degeneration in one kidney by ligation of the vessels and ureter and which is followed by degeneration in the cells of the other kidney, something that does not occur when the first kidney is removed. When the kidney undergoing degeneration is retained in the body the cells develop some substance capable of causing degeneration in kidney cells elsewhere in the body. This seems to Dr. Jackson very suggestive in regard to sympathetic ophthalmia, and he thinks Pusey's suggestion worthy of careful consideration. Both of Dr. Veasey's cases recovered on salicylates, but after enucleation of the exciting eye. The operations in one of Dr. Weeks' cases failed to influence the course of the disease, the exciting eye being retained. The statistics show different prognoses after removal of the exciting eye. Of course, where both eyes are injured the decision as to what should be done is a difficult one. The retention of the eye may have significance from many points of view, but it is a practical point on which there is a good deal of evidence that it is dangerous to retain a damaged eye. In Dr. Weeks' most successful case, where he extracted the lens and got good vision, he speaks of using irrigation with the extraction of the lens. Within the past year Browne and Stevenson of Liverpool have used prolonged irrigation with good results.

Dr. T. Y. Sutphen, Newark, N. J., stated that several years ago he brought to the notice of the American Ophthalmological Society the usefulness, in his experience, of salicylate of soda in secondary glaucoma. Since that time he has found it to be of great value in deep inflammations of the eye, not glaucomatous, whether the tension is increased or not. He is not surprised to find it of value in sympathetic ophthalmia. In support of the theory that the case of sympathetic ophthalmia reported may be due to irritation at the end of the optic nerve, he referred to a case, which he reported several years ago, in which sympathetic neuritis developed in the fellow eye three weeks after enucleation. Strong adhesions had formed between the stump and the under surface of the upper eyelid, which caused a pulling on the end of the nerve at every movement of the other eye. Recovery was prompt after these bands of adhesions were severed. The traumatism necessitating enucleation had been a wound of the upper lid and globe by a piece of blank cartridge.

Dr. J. L. Thompson, Indianapolis, declared that very few men could take the bold stand Dr. Theobald takes in the matter. Dr. Thompson had a case in which the germs must have been twenty-five years traveling around. One case had calcareous degeneration occur and sympathetic ophthalmia was set up twenty-five years after.

Dr. S. C. Ayres, Cincinnati, related a case relative to the subject of Dr. Weeks' paper. A young man, 20 years of age, came to him about eight years after the injury. The injured eye was shrunken and in the other there was a well-developed cataract. Dr. Ayres made an iridectomy and did an extraction. This was followed by exudate, and he did another iridectomy downward and incised the capsule. Then he made a V-shaped incision with De Wecker scissors and got a good open space with very good vision. That is one of the rare cases where sympathetic inflammation is followed by cataract *and good vision obtained by an operation.* In another case a man had an eye injured from a blow. The sympathetic eye and the other one were about equally imperfect. In course of time the sympathetic eye became blind and the injured eye regained good vision. That is an argument in favor of delay in operating. If the injured eye had been enucleated the man would have been entirely blind.

Dr. Robert L. Randolph, Baltimore, stated that during a long working experience in the pathologic laboratory of the Johns Hopkins University he has utilized numbers of the lower animals for the purpose of producing experimentally what is known as sympathetic ophthalmia and he has never seen in the second eye anything which was in the slightest degree suggestive of a sympathetic inflammation. He has frequently been asked by other workers in the laboratory to examine eyes of animals which had been used for other kinds of experiments; these animals showed eye symptoms, but in no case was the trouble anything more than either a conjunctivitis or keratitis, both of which diseases are, as we know, quite common among dogs and rabbits, especially when several are confined in close quarters. He has gradually reached the conclusion that the lower animals, certainly horses, dogs, rabbits and cats, do not have sympathetic ophthalmia, and he believes that all attempts to *produce sympathetic ophthalmia experimentally* will result in failure.

Dr. Clarence A. Veasey, Philadelphia, said that he trusted that the members present did not understand that his prognosis as to the ultimate result in the sympathetic eye of the second case was favorable. It was decidedly unfavorable. On the other hand, he is quite sure that a number of his Philadelphia confrères can recall the case exhibited before the College of Physicians by Dr. Zimmerman some years ago in which a large piece of brass had remained behind the lens fifteen years without producing any inflammatory symptoms. This also agrees with the statements of Leber on this subject. The point he wanted especially to make was that the disease in the second case was true sympathetic ophthalmia and that the condition was relieved by the use of large doses of salicylate of sodium. It has been the custom of Philadelphia oculists to employ the salicylates for many years in diseases of the uveal tracts other than those due to sympathetic trouble. Dr. Veasey got the idea from his friend and former teacher, Dr. de Schweinitz, and thinks that he received it from his former teacher, Dr. Wm. F. Norris, so that it dates back many years. The method is to give 80 gr. during the first twenty-four hours, 60 gr, during the second, and 40 gr. during the third twenty-four hours in most of the diseases of the uveal tract. In sympathetic ophthalmia, however, it is given in much larger doses, according to the body weight. Dr. Jackson says both cases recovered after removal of the exciting eye, but it should be noted that the patients did not recover until after the use of the large doses of salicylates.

Dr. John E. Weeks said that he should not think of saving the eye unless the chances or possibilities were that the vision in the exciting eye might finally be the better of the two. When an eye is attacked with sympathetic ophthalmia, one can not predict that the eye will recover with useful vision. In the cases that he reported, the resulting vision in the sympathizing eye is good to-day. In the cases of cataract following sympathetic ophthalmia, the exciting eye was not removed because he did not think it was in any way a factor at that time. It has not been his experience that removal of the exciting eye always stops the sympathetic process: in some cases it has no effect whatever. In regard to the third case, where cataract was removed, he remarked on a peculiar condition that was present as evidence of degeneration, namely, ribbon-shaped keratitis. The commencement of ribbon-shaped keratitis is an evidence of degeneration of the affected eye. This process ceased in the eye in which the operation was done. A year has elapsed. There has been an improvement in the condition of that eye and apparently a recession of the keratitis.

Dr. Samuel Theobald, Baltimore, stated that he discussed the value of the cytotoxin theory with Dr. Welch of the Johns Hopkins Hospital, and he thought that the knowledge regarding cytotoxins was not definite enough to warrant the establishment of such a theory. In Dr. Veasey's case, where both eyes were badly injured, and he regarded the trouble as sympathetic, it seems to Dr. Theobald not improbable that the supposedly sympathetic inflammation was really due to the injury. The fact that sodium salicylate acted favorably would have no bearing on the question of etiology. As to the disturbing effect of sodium salicylate on the stomach, some of the members, perhaps, have not had occasion to note how very favorably the essence of pepsin acts in this regard when given in connection with the sodium salicylate. For some years he has given from 1 to 2 drams of essence of pepsin with each dose of the sodium salt, and with the happiest effect.

FIFTY CONSECUTIVE CASES OF PNEUMONIA WITHOUT A DEATH.

W. J. GALBRAITH, A.M., M.D.,
Chief Surgeon Cananea Consolidated Copper Company.
CANANEA, SONORA, MEXICO.

In reporting the results of my method of treating pneumonia I wish to thank my many colleagues for the interest they have manifested in criticizing my article that appeared in The Journal, July 9, 1904, and to Drs. W. P. Haney, T. F. Butzow and T. R. McNab, my assistants. I am especially indebted for their untiring efforts to prove or to disprove the value of quinin and iron as I recommended them in pneumonia.

I believe pneumonia to be a septic, febrile disease, characterized, according to our present knowledge, primarily, by a severe lung inflammation and frequently by great cardiac weakness, which often causes death.

The present knowledge of the etiology (excepting exposure to wet, cold and alcohol) and pathology is somewhat limited, and I question the propriety of basing our management on the principles of theory alone. I am inclined to believe that an invasion of a combination of micro-organisms, or their products, are etiologic factors in pneumonia. However, there remains a doubt in my mind if there are not tissue changes elsewhere in the body that precede the active involvement of the lungs.

The fact that I have been able to detect in several cases tenderness and pain, from a mild to a severe degree, in the region of the gall bladder during the first stage of the disease, has strengthened my theory of primary gall bladder invasion. In those cases that are preceded by liver pain and bilious vomiting, troublesome tympanites invariably follow: What relation, if any, these preliminary symptoms have to pneumonia, and the factors that produce these symptoms, are difficult, or impossible, to explain.

I doubt if any disease has occasioned more discussion concerning its etiology and treatment than pneumonia, and, moreover, he who advocates a departure from a measure that is not based on some etiologic or pathologic finding is more formidable in the eyes of the profession than any medical measures he may present.

While differing from nearly every writer on pneumonia, I do not wish it understood that I look on their efforts as unavailing, as no disease presents more individual suggestions from a symptomatic standpoint, or necessitates more active attention. As my exceptions of the present consideration of pneumonia are based on my own experience, I feel at liberty to frankly express these views.

To those who believe my success is due to a modified form of pneumonia, or a malarial infection, I wish to state that I have never experienced more desperate cases in my life, as the report of the following cases, which are fair examples of the pneumonia we have in this section of the Southwest, will confirm. So far as malarial influence is concerned, I have never seen a case of malarial infection during my residence in this locality.

Dr. J. B. Showalter of Butler, Pa., was a frequent visitor to the bedside of Case 1 during the fifth, sixth and seventh days of the patient's illness.

Case 1.—L. M., aged 34; single; Mexican; occupation, mine laborer.

History.—He was taken ill on the evening of Oct. 31, 1904, and was admitted to hospital November 1, at 11 a. m. The alleged cause of disability was exposure, due to change of clothing in a cold room after coming from the overheated mine.

Examination.—Axillary temperature 105.2; pulse, 110; respiration, 36, and somewhat labored; severe pain in left chest extending to left shoulder posteriorly; also pain and tenderness in the region of the gall bladder, with nausea, and vomiting of about six ounces of bilious matter.

Diagnosis.—Pneumonia involving the upper lobe of the left lung. Unusual depression was noticed in this case, which was greatly aggravated by almost constant coughing, and during the frequent paroxysms cyanosis was very much in evidence.

Treatment.—Forty-five grains of quinin were administered at 12 m. and 30 grains more were given at 1 p. m. At 5 p. m. his temperature was 104; pulse, 100; respiration, 32, at which time 20 grains more of quinin were given. Temperature, 7 p. m., 103.8; pulse, 98, full and strong; respiration, 30; 15 minims of the tincture of chlorid of iron was ordered every three hours.

November 2: 7 a. m., temperature, 103.8; pulse, 100; respiration, 30; iron continued. 12 m., temperature, 104; pulse, 100; respiration, 30; pain in left side somewhat relieved; 40 grains of quinin administered. 4 p. m., temperature, 102; pulse, 100; respiration, 36; patient very restless; sputum remaining clear; stomach rebellious and patient vomited about four ounces of bilious matter and milk about 7 p. m. Iron continued.

November 3: 7 a. m., temperature, 103; pulse, 98; sputum slightly streaked with blood. 4 p. m., temperature, 103.6; pulse, 100; respiration, 34.

November 4: 8 a. m., temperature, 103; pulse, 90; respiration, 32; profuse prune juice expectoration. 12 m., temperature, 104; pulse, 100; respiration, 30; entire lung and right lower lobe involved; 45 grains of quinin administered. 8 p. m., temperature, 103; pulse, 100; respiration, 34; iron continued.

November 5: 7 a. m., temperature, 103; pulse, 104; respiration, 40; slightly delirious. 12 m., temperature, 104.6; pulse, 108; respiration, 40; complaining of pain in the region of right lower lobe. 5 p. m., temperature, 103; pulse, 100; respiration, 38, and of good character; complains of but little pain. Twenty-five grains of quinin were administered, which he immediately vomited. Twenty-five more were given 30 minutes later and were retained. Iron increased to 20 minims every 2 hours. 10 p. m., temperature, 101; pulse, 96; respiration, 30; demanding more nourishment.

November 6: 7 a. m., temperature, 100.4; pulse, 90; respiration, 24; 15 minims of iron ordered every 4 hours. 8 p. m., temperature, 101; pulse, 92; respiration, 32; slightly nervous; 30 grains of bromid and 10 of chloral ordered.

November 7: 8 a. m., temperature, 99; pulse, 88; respiration, 22; complains of being hungry and insists on being bolstered up in bed to eat his mush, poached eggs and milk toast. Evening temperature, pulse and respiration practically normal.

November 10: Advice from the patient states that he is practically well.

Case 2.—J. M.; Mexican; aged 38; laborer; occupation, miner.

History.—He was taken ill July 5, and admitted to hospital July 9, after occupying a tent for four days where the rain almost constantly beat on him, and with practically no attention. His condition when admitted to the hospital was as follows:

Examination.—July 9: Axillary temperature, 106.4; pulse, 140, very weak and soft; respiration, 60; very cyanotic and semi-unconscious, and with a most distressing expiratory grunt. Extremities were cold and clammy, and it certainly looked as if he would die in a very few hours.

Treatment.—With difficulty he was aroused and 75 grains of quinin were administered. In one hour later 40 grains more were administered. At 5 p. m., two hours after the first dose of quinin was given, his temperature was 105.2; pulse, 122; respiration, 48; at which time he began to show a rational condition. Twenty minims of tincture of iron were ordered every hour for three doses. At 8 p. m. 40 grains more of quinin were given, with the result that at 8 a. m. the next morning, July 10, his temperature was 102.2; pulse, 110; respiration, 24; practically free from pain; very little expectoration, which was slightly prune juice in color. The patient was discharged from the hospital July 17, practically well.

Case 3.—The following case was treated by one of my assistants, Dr. W. P. Haney.

History.—Mrs. M., aged 24; Mexican; weight, over 200 pounds; mother of two children; was taken ill Oct. 1, 1904. Slight chill about 10 a. m., followed with frontal headache; pain in the eyeballs and in the muscles and bones of the thighs and lumbar region; temperature, 104.6.

Diagnosis.—La grippe. A calomel purge, followed by Dover's poowder and salicylate of soda, was ordered.

October 2: 10 a. m., temperature, 103; pulse, 140; respiration, 26; salicylate of soda and salol ordered. During the day of October 2 she complained of but little pain in her bones and muscles, and at 8 p. m. she was fairly comfortable.

October 3: 11 a. m.. the patient was seized with a chill, followed by severe pain in the region of the right lung, lower lobe, with extreme tenderness in the region of the gall bladder. Dyspnea was marked; temperature, 105.8; pulse, 120. All the physical signs of pneumonia were present, including profuse bloody expectoration. A diagnosis was made of pneumonia, right side, complicating grippe.

Treatment.—Fifty grains of quinin were administered at once, followed in one hour by 30 grains more; 15 minims tincture of iron were ordered at 10 p. m., to be repeated every two hours.

October 4: 8 a. m., temperature, 103; pulse, 102; respiration, 26; 35 grains of quinin were administered at 9 a. m., followed in one hour by 20 grains more; iron continued. At 9 p. m. the third complication was discovered by her aborting, at about the sixth or seventh week. Notwithstanding the serious complications, she was discharged October 7, practically well. I doubt if quinin had as much to do with this patient aborting as the high temperature, as my experience has been that women frequently abort from la grippe when the temperature reaches 105 or over.

Case 4.—J. D., aged 38; Mexican; miner; was taken ill September 30; Dr. Haney first saw him October 2, 4 p. m.

Examination.—Axillary temperature, 105.8; pulse, 128; respiration, 56; profuse prune juice expectoration; pain in both sides of chest, severe in right side.

Diagnosis.—Double pneumonia.

Treatment.—Fifty grains of quinin were given at 4:15 p. m., followed by 30 grains more at 5:15 p. m.; 15 minims of iron were ordered every two hours. The patient was admitted to hospital the following morning, October 3, 10 a. m. Temperature, 102.2; pulse, 102; respiration, 34. Thirty-five grains of quinin were given at 11 a. m.; iron, 15 minims, every three hours.

October 4: Temperature and pulse were practically normal and remained so; he was discharged October 8, well.

A careful review of the above cases will show that in one hour or one hour and fifteen minutes after administering quinin the condition of the patient was improved. While improvement at this early period of the disease is gratifying, it is no comparison to the results achieved by the treatment in preventing the dangerous symptoms of cardiac failure, commonly called crisis. No selection of cases has been made for the purpose of this record, as I hastily took a synopsis of these few cases on the date of my departure for the United States.

Case 2 may be looked on as a lucky one, but it will take a great amount of evidence to convince me that the treatment did not save his life.

I have proved that quinin will not depress the heart in any stage of pneumonia; on the contrary, it is the most reliable stimulant, and produces the effect that we have so often looked for in strychnin and alcohol. Quinin, as I administer it, will not only reduce the frequency of the heart, but will increase its volume and the peripheral circulation as well. Again, to prove its indications, I have but to state that not in a single instance, where large doses have been administered during the active stages of the disease, has cinchonism been observed; in fact, not an unfavorable symptom has been recorded. That iron is a principal factor in maintaining the strength of the heart, as well as in acting as an antiseptic, there can hardly be a doubt.

I maintain that our principal efforts should be directed to applying measures that will fortify the heart and destroy the products of organisms that produce sepsis.

In quite a number of recent cases I have noticed that the rusty sputum has been delayed until the third or fourth day of the disease, and continues only one or two days, probably due to a mixed infection or the treatment.

Just what the blood count will show after the administration of large doses of quinin and iron in pneumonia is speculative on my part, but I venture to say a favorable report will be made.

The fact that many of the older practitioners claim to have given quinin in big doses, not alone in pneumonia but in nearly every inflammatory disease, does not interfere with my unique method of treatment.

that is based on clinical observation and specific conditions for its administration.

To enumerate the diseases that have been treated by large doses of quinin would be as difficult a task as it would be to recite the authorities on its use since its discovery by Dr. Duncan of Edinburgh in 1803.

The record of Case 2 shows that 115 grains of quinin were given the patient within one hour after his arrival at the hospital. This may impress many as an aggressive measure, but, regardless of any impression of this character, I believe the future will record many larger doses. Experience will, no doubt, demonstrate that the timid practitioner will reserve the application of this method as a substitute for strychnin and alcohol, which are so frequently administered during the excitement prior to dissolution.

I strongly maintain that the use of stimulants, alcohol and strychnin, prior to the stage of resolution, is a dangerous practice, as it increases the mechanical conditions that are distressing the patient instead of strengthening the disabled heart.

I find that bromid of lithium in combination with chloral controls the nervousness and delirium which is probably produced by toxemia, much better than does morphin, as the latter given in sufficient quantity to alleviate these conditions not only embarrasses respiration, but interferes with the secretions.

It would not be surprising if the near future revealed some interesting knowledge concerning the incubation period.

The absence of complications, with one exception, in the last 50 cases, has possibly been influenced by the treatment. I do not feel justified, however, in making any positive claims of this character on so limited a number of cases.

I have discarded all external applications, and dress my patients with as light-weight clothing as possible. Expectorants, excepting as a vehicle, are seldom used. A liquid diet, with plenty of plain alkaline drinking water, is advisable. The syrup of glycyrrhiza and yerba santa is an excellent agent in which to suspend quinin, and also acts as a pleasant cathartic. Carbonated waters and solid food should be avoided prior to beginning resolution, as any distension of the stomach will not only interfere with respiration, but will embarrass the heart action.

We have been taught that it is impossible to modify or to shorten the duration of this disease; but must we go on indefinitely and accept such an ultimatum, or should we, on our own responsibility, lend efforts that will secure more practical results?

To associate therapeutics with the expectant plan of treatment is objectionable on account of the lack of any specific agent; watching and waiting and expecting Nature to cure so formidable a disease as pneumonia does not impress me as rational or modern medicine.

In the 50 cases responsible for this article, the ages ranged from 7 to 56 years. In nearly 80 per cent. the right lung was attacked, principally the lower lobe.

The most prominent feature that recommends my treatment of pneumonia is the practical absence of cardiac depression and the early resolution that invariably follows. Broken or small doses of quinin and iron will not produce satisfactory results.

The 50 consecutive cases of pneumonia that I have now treated without a death were diagnosed in every instance by thorough examination.

The administration of quinin during the stage of resolution must be carefully watched, as small doses of from 5 to 10 grains will frequently produce cinchonism.

THE MOST ANCIENT MEDICAL PRACTICE LAWS.

THE CODE OF HAMMURABI, 2200 B. C.

BAYARD HOLMES, M.D.
CHICAGO.

It has long been known that there was a celebrated lawgiver in the valley of the Euphrates called Hammurabi or Amraphel.[1] He was king of Babylon, and his rule extended over the whole of Mesopotamia from the mouths of the Tigris and Euphrates to the Mediterranean coast. There are frequent references to the code of Hammurabi in the Chaldean and Assyrian writers, and a few of his laws have been more or less perfectly known for half a century. He is supposed to have lived between 2885 and 2242 B. C., or about the time of Abraham.

Every physician will have a certain interest in knowing that nine of the 282 laws of Hammurabi refer to surgeons. These laws were discovered written on a monument of stone, eight feet high. It was found at Susa, Persia, in January, 1902, and in October of the same year a superb reproduction and translation of this oldest code of laws was published by the French government. The medical reader will be interested in the translation made by C. H. W. Johns and published in Edinburgh in 1903, or if he be more of an archeologist he will be delighted with the magnificent transliteration and translation by Robert F. Harper and published by the University of Chicago. It is worth while here to reproduce the nine paragraphs referring to medicine.:

215. If a doctor has treated a rich man for a severe wound and used a bronze lancet, and has cured the man, or if he has opened the eye of a rich man with the bronze lancet and has cured the eye of the rich man, he shall receive ten shekels of silver.

216. If the patient be the son of a poor man, he shall take five shekels of silver.

217. If he be a gentleman's servant, the master of the servant shall give two shekels of silver to the doctor.

218. If the doctor has treated a rich man for a severe wound with a lancet of bronze and has caused the rich man to die, or if he has opened an abscess of the eye of a rich man with a bronze lancet and has caused the loss of the rich man's eye, one of his hands shall be cut off.

219. If a doctor has treated the severe wound of a slave of a poor man with a bronze lancet and has caused his death, he shall render slave for slave.

220. If he has opened the abscess of a slave with a bronze lancet and has made him lose his eye, he shall pay half the slave's price in money.

221. If a doctor has cured the shattered limb of a gentleman, or has cured the diseased bowel, the patient shall give five shekels of silver to the doctor.

222. If the patient is a poor man, he shall give three shekels of silver.

223. If he is the servant of a gentleman, the master of the slave shall give two shekels of silver to the doctor.

It appears from these laws that the physician and surgeon occupied a distinct social position in the ancient Assyrian society, and that even in those remote periods the surgeon was considered worthy of compensation. He received from the rich man a larger fee than from the poor man. He evidently made a good living, because he is supposed to have a slave to render for a slave and the money to pay for half the value of a slave in case a slave should lose his eye at the surgeon's hand. We may believe that in those remote days the abdomen was occasionally opened, because the fee for treating the sick bowel of the gentleman is distinctly mentioned, but no penalty is given outside of the general one in paragraph 218 for a failure to cure.

In the succeeding paragraphs of this code the veterinary is

---

[1] Genesis, xiv. 1.

mentioned, and he receives compensation in a much smaller degree for his services, and he is obliged also to suffer when he fails to cure.

In the preceding paragraph of the code, 209, an interesting law is promulgated: "If a man has struck the daughter of a gentleman and has caused her to miscarry, he shall pay ten shekels of silver for the miscarriage." It will be noticed that this is the price of a capital operation on a rich man.

Taking the code all in all, one is compelled to look on the civilization of the Euphrates 4,000 years ago as marvelously similar to our own except possibly for its lack of bookish culture. The view of life which is given in the code is imperfect, but many outlines of that civilization are sketched in a master hand. They had means of transportation, common carriers and public servants, who were under more obligation and stricter rules and regulations than private individuals. They had storehouses, commission merchants, money lenders and borrowers of money and renters of real estate, and in many respects their laws in relation to these economic factors were more humane, equitable and reasonable than our own.

At this particular juncture one might ask if the commission business existed among physicians and surgeons in the valley of the Euphrates. But on this point the code is silent. If the man with the bronze lancet had runners out, either in the guise of female booksellers and male peddlers of patent preventatives, or commission men practicing among the Elamites or in the suburbs of Babylon, no cases of the kind ever came to djudication and monumental inscription in the market place Susa.

A number of laws are devoted to the relations of man and wife, to fidelity and infidelity between them, and to other sexual and household economic affairs. They form a very considerable part of the code, paragraphs 129-184 inclusive. Noticing an abstract in The Journal, November 12, page 1485, in which Baudouin is said to be awaiting with interest the article yet to be written on the husband of the medical woman, I wish to recall the fact that a matter of this sort was recognized by the code of Hammurabi, and that several paragraphs were necessary to regulate the conflicting relations of such a husband and wife. In paragraph 144 is the first mention of the relations of such a husband to such a wife, namely: "If a man has espoused a votary and that votary has given a maid to her husband, and she has brought up children, and that man has set his face to take another wife, one shall not countenance that man; he shall not take another wife." Paragraph 145: "If a man has espoused a votary and she has not granted him children, and he has set his face to take another wife, that man shall take another wife; he shall cause her to enter into his house. That other wife he shall not put on an equality with his wife." In two succeeding paragraphs it denies the woman the privilege of selling such a maid who has borne children to her husband, but allows her to sell one who has not borne children.

If it were possible, if by any means it could be brought about, the attention of the conferences, dioceses and houses of bishops ought to be called to these paragraphs of the code, 129-184, and carefully considered in their bearing on the prevention of marriage of either party after divorce or the prevention of divorce itself.

Physicians as Statesmen.—The medical profession is fairly well represented in the Canadian Senate as well as in the Canadian House of Commons. According to the *British Medical Journal*, there are nine physicians in the former and fifteen in the latter body. France is still the country where medical men are most prominent in politics; in the Senate there are thirty-nine, and in the Chamber of Deputies fifty-one. Many of them, however, like M. Combes, M. Clemenceau, and M. de Lanessan, are politicians first and physicians only to the extent of holding a diploma. The *Lancet* states that in the Italian parliament, which was recently elected and is now in session, there are twenty-two medical deputies, representing wards in eighteen provinces of Italy. The list includes several well-known names, such as Baccelli and Santini for Rome, Celli for Cagli, Sanarelli for Bibbieno, and Rummo for Benevento.

Special Article.

IMMUNITY.

CHAPTER I.

PARASITISM, INFECTIOUSNESS, CONTAGIOUSNESS.

Parasitism.

Parasitism is the condition in which a plant, or an animal being, lives on or within another living organism. A true parasite always derives its sustenance from the tissues of its host.

Some parasites may live on a host without causing appreciable damage, that is, they are non-pathogenic parasites. In this case they may derive their nutrition from some of the excreted non-living products of the host, living as pure saprophytes,[1] or the amount of nutritious substance which they obtain from the host may be so little that the health of the latter is not impaired.

There is another large class of organisms, however, which under the proper conditions cause severe diseases in the host. For example, there are many pathogenic microbes which live in and on the skin without doing harm, but if certain ones reach the deeper tissues, they may institute pathologic processes. *Any organism which is able to cause pathologic tissue changes or to set up abnormal symptoms is classed as a pathogenic parasite.* The abnormal processes which they set up are our infectious diseases.

Infectious Disease.

An infectious disease is one which is caused by living organisms which have in some way been introduced into the tissues of the body. Accordingly the word has reference to the nature of the cause of the disease. It is from the Latin *inficire*, meaning to place in or into.

Infestation and Infection.

Where living organisms exist on a body surface, as the skin or intestinal tract, the surface is said to be infested; the skin, for example, is infested with pediculi. One may also say that the intestinal tract is infested with tape worms, but here the distinction between infestation and infection is not to be drawn so sharply; surely when the larvæ penetrate the intestinal wall and reach the circulation or distant organs we must speak of infection. But even the adult tenia as it exists in the intestines may cause erosions of the mucous membrane or may perhaps burrow a slight distance into the wall, a condition which approximates the action of the larvæ in passing through the wall; accordingly at some point the distinction between infestation and infection would have to be an arbitrary one. It is more convenient to confine one's self to the word infection.

Contagiousness and Infectiousness.

Confusion sometimes arises in using the words infectious and contagious. A contagious disease is one which may be transmitted to another by direct or by indirect contact with the one who is suffering from the infection; the word has reference to the manner of transmission of an infection. Non-infectious diseases are never contagious. Contagiousness is well illustrated in those diseases in which the transmission takes place through the air, as seems to be the case in smallpox and scarlet fever. Here there may be a contagious zone of atmosphere surrounding the patient, in which the virus is present, and by which the agent reaches the lungs of one within the zone. Contagiousness is even more striking when it takes place through the medium of some inanimate substance, such as clothing or toys, which were previously within the contagious zone or in direct contact with the patient. Such substances, fomites, were formerly thought to be of great importance in the spreading of yellow fever; a theory which has been entirely exploded by the proof that this disease is spread by the bites of infected mosquitoes.

---

[1] A saphrophyte is defined as a vegetable organism which lives on dead organic matter. An organism which is habitually saphrophytic may be under the proper conditions a pathogenic organism (bacillus of malignant edema). And, on the other hand, a pathogenic parasite lives a saprophytic life when it grows in our artificial culture media.

Contact Infection.

Infection Atrium.

Typhoid fever is not highly contagious. There probably is no infected zone of atmosphere about the patient in the sense that there is about a scarlet fever patient. Yet it frequently happens that the nurse contracts the disease while caring for her patient. It is likely that she has in some way transferred the bacteria from the patient's sputum, urine, feces or skin to her lips or hands so that eventually they found their way to the intestines. At the same time it is not improbable that the point of entrance for the germs, i. e., the infection atrium, may at times be the lungs, the bacteria having been inhaled. However, typhoid fever is usually a "water borne" disease, seldom "air borne."

We are to look on malaria as a strictly non-contagious disease, although no doubt is possible as to its infectiousness. No amount of personal contact with the patient will transmit it to another. To accomplish transmission the parasite must be actually injected into an individual, an event which happens exclusively, it is believed, through the bite of a mosquito which had previously fed on the blood of a malarial patient. In all probability the same is true of yellow fever.

Tetanus is another noted example of an infectious disease which is not acquired by contact with one suffering from it.

The special methods of transmission which are utilized by the different infectious agents will be taken up later in considering immunity to the individual diseases.

Pathogenesis.

The various parasites have different ways of injuring the body. The itch mite burrows into and beneath the epidermis, causing mechanical irritation as well as the inflammatory reaction produced by its toxic excretions. The loss of blood caused by some intestinal parasites, and the hemorrhage which follows from the wounds, often leads to grave anemias and the general changes which are caused by such anemias. This is especially the case in the duodenal infection with *Ankylostoma duodenale* (ankylostomiasis).

A certain variety of *Filaria sanguinis hominis* produces disorders by mechanically blocking the lymph channels.

The plasmodium of malaria, aside from the febrile disturbances seen in malaria, causes anemia by the destruction of blood cells.

Mechanical and Toxic Injuries.

It is generally said that the bacteria produce disturbances in both a mechanical and a toxic way. However, the more we learn about bacterial infections the more important do the toxic phenomena become. It is doubtful if any pathogenic bacterium is entirely devoid of toxic powers.

In lobar pneumonia we have a good example of a mechanical disturbance of importance. The alveoli become filled with a fibrinous and purulent exudate which makes a large area of pulmonary tissue unavailable for respiration. Yet, even here, the mechanical disturbance has arisen only as a result of the previous toxic action of the pneumococci on the capillary walls and the alveolar epithelium, permitting the escape of the blood and serum; and the accumulation of the leucocytes is no doubt due, in part, to the toxin of the coccus rather than to the bacterial cells alone.

It is probable that the emboli of bacteria which are sometimes found in the capillaries and small arteries cause disturbances through the shutting off of so much circulation, but still greater damage surely results from the toxins which are formed by the microbes making up the emboli.

Effects of Toxins.

The toxins of bacteria often show a remarkable selective action on one organ or another. Some bacteria through their toxins destroy the red blood cells to a great degree (staphylococcus and streptococcus); other toxins have a special affinity for the nervous tissue (tetanus); some attack particularly the endothelium of the vessels, causing many minute hemorrhages; in diphtheria and typhoid numerous areas of necrosis are found in the lymphatic structures. It is a somewhat common property of bacterial toxins to cause areas of necrosis in the parenchymatous organs, such as the liver and kidney. The consequences of such necroses depend naturally on their extent. It is said that in anthrax infections all the glycogen may disappear from the liver, and we would expect the functions of various organs to be affected through similar toxic actions. The albumin and casts which appear in the urine in many acute febrile diseases are, of course, the result of toxic action on the epithelium and endothelium of the kidneys.

A conspicuous effect of the micro-organisms which cause some chronic diseases is the development of new connective tissue and vessels; this is seen especially in tuberculosis, syphilis and actinomycosis. The import of the new connective tissue depends on its location. A large amount of it may form in the pre-existing connective tissues with no consequent harm, but if even a small amount of such tissue has been formed in a suitable place in the brain, as may happen in syphilis, the results may be grave.

Infectious Substances.

It has been stated above that infectious diseases are caused by living pathogenic organisms. Investigations have shown, however, that the toxic products of some organisms can be obtained and separated from the organisms themselves by filtration, and that the microbe-free toxins when injected into animals will cause the same symptoms as the bacteria themselves (tetanus and diphtheria). Accordingly, for the sake of convenience, these toxins may also be considered among the infectious agents when they are separated from the bacteria. The various infectious agents, including these toxins, find their proper places in the following classification, which for the most part is that of von Behring:

I. Living (i. e., pathogenic parasites).
  A. Macroparasites (e. g., intestinal worms, pediculi).
  B. Microparasites.
    1. Bacteria (fission fungi, i. e., each cell divides into two in proliferating).
    2. Fungi of more complex organization (e. g., aspergillum, oidia).
    3. Protozoa (e. g., *plasmodium malariæ*, *ameba coli*).
II. Non-living (i. e., toxins).
  A. Animal toxins (e. g., snake venom).
  B. Vegetable toxins.
    1. Non-bacterial (e. g., abrin, from the jequirity bean; ricin, from the castor oil bean; these are strong red corpuscle poisons, but are only of experimental interest).
    2. Bacterial.
      a. Soluble bacterial toxins (diphtheria and tetanus).
      b. Intracellular bacterial toxins, which are not separable from the cells in a soluble form.

(*To be continued.*)

Ozena.—Dionisio reports a number of cases treated by phototherapy and by radiotherapy with good results—amelioration or cure. In the *Rev. Hebd. de Laryngologie* he suggests the conclusion that light has a slow but constant curative effect on the ozenic process. Its immediate action is excitation of the mucosa, causing, when the light is intense, sneezing and hypersecretion. He has, however, never seen any serious inconveniences from this treatment except transient headache and vertigo. The effect of the light is evident not only in the parts most directly exposed but also elsewhere, and in most cases the sense of smell is either improved or fully restored. He attributes the effect to the antiseptic action, but still more to the improvement of nutrition by the action of the light. Similar good effects have been obtained by him in suppurative otitis and in certain forms of dry pharyngitis and catarrhs of the nose and posterior fossæ. There are certain difficulties in the treatment requiring special apparatus, which may embarrass the general practitioner and require or make more convenient the recourse to specialists or especial institutions for the light treatment.

SATURDAY, JANUARY 28, 1905.

AUTOGENOUS REGENERATION OF NERVES.

The experiments of Bethe of Strassburg are attracting, and rightly, the attention of neurologists to an unusual degree. It would appear that Bethe has definitely established the fact that, on section of a peripheral nerve trunk, the distal portion can regenerate, in young animals at least, without any connection with the central stump. He has made a large series of experiments on the sciatic and other nerves. He excises long pieces and transplants the central stump so as to render any subsequent union with the distal trunk impossible. He has demonstrated that the myelin sheath and neurofibrils as well as the axon regenerate; he has shown that when regenerated the nerves are capable of conducting impulses; and more, that if the regenerated fiber be cut again the peripheral portion degenerates to the periphery, while its central portion, unconnected with either center or periphery, remains for a long time undegenerated. Conscientious autopsies have proved that the suggestions of Münzer and of Langley and Anderson that the regeneration can be accounted for by ingrowth of medullated fibers from branches of neighboring nerves to muscles, are without observational foundation. The regeneration occurs through the activity of the neurilemma cells in the course of the degenerating nerve. Regeneration is not due to the end organ, for Bethe has cut the sciatic high up and also in the popliteal space, has brought the two ends of this isolated piece together, has sutured them into a ring, and regeneration still occurred. Complete autogenous regeneration appears to be possible only in young animals. In adult animals the regeneration is incomplete if it occurs at all, owing, in all probability, to the lack of sufficient energy on the part of the tissues to carry on the process.

These recent experiments throw new light on the trophic function of the neuron. It was formerly supposed that regeneration occurs always by outgrowth of the axons in the central stump, and that it depends on trophic influences passed along the axons from the ganglion cells. Now we know that the peripheral fiber can regenerate when it is absolutely deprived of all influences reaching it from the central ganglion cell. Bethe admits that after autogenous regeneration occurs, connection with the center is necessary for the permanent welfare of the nerve, for otherwise it again undergoes slow atrophy and degeneration. The fact is established, however, beyond dispute, we think, that in young animals the dependence of the nutrition of a peripheral nerve fiber on the cell body of the neuron of which it forms a part is far less important than we have been accustomed to believe.

It should be noted that Bethe's work is in reality the continuation of some work done by Howell and Huber in 1892. These observers demonstrated autogenous regeneration of what they called "embryonal fibers," but they did not follow the process far enough to observe the complete regeneration of the fiber, as Bethe, by using young animals, has been able to do.

A review of the literature reveals the remarkable fact that the whole process of autogenous regeneration was accurately observed and described as long ago as 1859 by two French observers, Philipeaux and Vulpian. These investigators excised large pieces of the sciatic, median, hypoglossal and lingual nerves in young dogs, guinea-pigs and chickens, performing the experiments in a way that rendered union of the central and peripheral stumps difficult or impossible. They exposed the nerves after some months, and found that they did not have that shrunken appearance which is characteristic of degenerated nerve trunks; instead, they looked white *and plump and felt firm. On mechanical and electrical* stimulation of these peripheral nerve trunks, they were able in the case of motor nerves to cause contraction of the corresponding muscles, while the animal itself reacted in no other way to the stimulation. They examined the regenerated nerve trunks under the microscope and found large numbers of typical nerve fibers with myelin sheaths and axis cylinder processes. They further showed that if the regenerated nerve were cut a second time in its course, the peripheral portion underwent a second degeneration, while the central, now isolated, end remained intact. They felt sure that the nerves had really regenerated and had not simply remained undegenerated, for examination of control animals a few days after section demonstrated complete degeneration and entire loss of excitability. Philipeaux and Vulpian, therefore, concluded that autogenous nerve regeneration following complete degeneration is possible in young animals, and they put forward the view that, even in adult animals, no outgrowth of new fibers from the central stump occurs.

The findings of Philipeaux and Vulpian were not confirmed by other observers. Schiff seems to have repeated the experiments on animals 5 months old with negative results, and other writers denied the possibility of the results apparently without actually trying experiments for themselves. Vulpian himself took up the subject again in 1874. He repeated the experiments with results similar to those formerly obtained, but, curiously enough, interpreted his findings differently. He concluded that the regenerated fibers found must have come in through anastomoses with neighboring nerves—anastomoses too small to be visible to the naked eye. His interpretation was in accord with the views of Wallerian degeneration and regeneration which had come to prevail. Subsequently the new histologic methods were introduced which permitted of a better staining of the axis cylinder processes. Stroebe. von Notthaft and others thought that they brought irrefragable proof that in the repair of nerves the regenerated axons always grow out from the central stump into the degenerated nerve. The scientific world accepted their conclusions, especially as at about this time the neuron doctrine was developed, the supporters of which at first laid great emphasis on the cell as an absolutely independent histologic and physiologic unit.

We have pointed out in these columns at various times the gradual modifications which the neuron doctrine has undergone. Our readers will recall that many histologists now believe that the neurons, though still legitimately to be regarded as the most important architectural and physiologic units in the nervous system, are not as absolutely separated from one another structurally, nor as totally independent of one another physiologically, as it was thought that they were when Waldeyer formulated the doctrine in 1891. Indeed. many believe that the "contact doctrine" must be given up and that a more intimate interneuronal connection must be granted. Nissl and a few others, wrongly confusing the "contact doctrine" with the neuron doctrine as a whole, have advocated that the latter be abandoned. The majority of the anatomists, physiologists and clinicians working on the nervous system, however, hold as firmly as ever to the neuron doctrine in general. though they modify it in detail.

An important service has been done by Bethe in repeating and extending the experiments mentioned and thus rescuing from oblivion the valuable discoveries of Philipeaux and Vulpian.

THE PORTLAND SESSION AS AN ATTRACTIVE VACATION.

The American Medical Association will hold its next annual session at Portland, Oregon, July 11-14. This place of meeting—far to the West—will require a journey of unusual length for those living east of the Mississippi, and especially for those in the New England and Atlantic Coast states. Many who are in the habit of attending the Association sessions will naturally hesitate before deciding to take such a long journey simply to attend the session—valuable as that privilege is—but the occasion offers an unusual opportunity for a splendid vacation, and this was one of the reasons why the date was made a month later than usual.

Our object at this time is to emphasize this fact: The trip to Portland and return may be made a memorable one if those who propose to take it will study out the possibilities beforehand. The vast territory west of the Missouri River is an unknown country to the majority of the members of the Association, but it is a country so full of grand scenery, natural wonders and boundless, undeveloped, natural wealth that to see it alone is worth all the trip will cost. The railroads of the West are much more liberal than are those of the East in allowing passengers to break the journey at attractive points, and each road is already making preparations to accommodate and to please those who patronize it. Of course, no one will go and return the same way, and as there are fifteen or twenty different routes, and as each has some special attraction to offer, it will not be an easy matter to decide which two promise the most. The possibility of visiting Alaska, northwest territories, Hawaiian Islands, California, Mexico, etc., on this trip is also worth considering. We expect shortly[1] to give a brief description of the various routes, but we advise those interested to write to the various railroads for circulars and for any information they may desire. The rates, as we have before intimated, will be $45 from Missouri River points, to which must be added the fare from points east of the Missouri River, which will probably be one fare for the round trip.

One of the great attractions, if not the greatest, will be the Yellowstone Park. If a sufficient number can be secured, THE JOURNAL proposes to arrange for a special train to start from Chicago June 30; this will stop six days at the park, arriving in Portland Monday morning. We can promise those who patronize it a most enjoyable outward journey. Arrangements will have to be made with the park management some months ahead, and hence it is necessary to know very soon if a sufficient number can be depended on to warrant arranging for the dates. Will those who desire to visit the Yellowstone Park on the way to Portland write us?

CONGENITAL ICTERUS WITH SPLENOMEGALY.

The large amount of study which has been devoted to the spleen in the last few years has led to a reclassification of splenic diseases. The association of certain forms of splenomegaly with hyperglobulia, and of other forms with anemia has been well emphasized in recent literature. Some writers have classed with splenic anemia certain cases of icterus associated with enlargement of the spleen, which recent study teaches belong in a class by themselves. According to von Krannhals,[2] who has quite recently collected all of the published cases, the association of congenital icterus with chronic spleen tumor was first noted by Minkowski in 1900. One writer has remarked "the new things in medicine are the things which have been forgotten," and von Krannhals has overlooked the fact that similar cases were reported by Claude Wilson[2] as early as 1890.

---

[1] Information regarding the Portland session, railroad rates, etc., appears frequently under "Association News." In this issue hotel arrangements are described. Under Queries and Minor Notes also is some information in reply to a correspondent.

[2] Deutsches Archiv für klinische Medizin, vol lxxxi, Nos. 5 and 6.

The disease seems to be one which must be added to the few perfectly definite family diseases, though it does not seem to follow such definite lines of transmission, as does hemophilia, for example. There is some evidence to show that it is usually transmitted from mother to son, and from father to daughter. The main lesions are icterus, congenital in character, and associated with more or less enlargement of the spleen. The icterus usually varies in intensity from time to time, and in some cases is markedly influenced by the emotions, especially anger, or by exposure to cold. In some cases overindulgence in food or in alcoholic drinks served to intensify the icterus. In some instances the patients complained of no interference with their health, in others more or less serious disturbances, usually in the form of gastroenteric derangements, occurred from time to time. In some of Wilson's cases these attacks were accompanied by fever, and in all in which they occurred the jaundice was generally intensified. Skin affections, such as usually accompany obstructive icterus, are uncommon; a few patients had at times urticaria, xanthelasma or pruritus. Nearly all were dark-haired, sallow individuals who would be classed under the bilious temperament. In some instances nervous disturbances in the form of neurasthenia or hysteria were present. In one or two cases pains in the joints and even rheumatoid arthritis occurred. Aside from the icterus, the only constant physical sign was the enlargement of the spleen, which was in nearly all cases palpable, usually hard and described on palpation as resembling the spleen of chronic malaria. The liver was usually unaffected, though in a few cases it was slightly enlarged and tender, and one or two patients suffered from gallstones as a complication. The urine was at times normal, though in many cases it contained traces of urobilin. The stools did not show lack of coloring matter except in one case of the 26 collected by v. Krannhals. The blood in all carefully observed cases has shown more or less anemia; v. Krannhals noticed also a considerable variation in the size of the red cells and that a great many cells showed polychromasia.

Only one autopsy has been performed in this condition and that was in the case of Minkowski. The important lesions were found in the spleen and kidneys. There was no cirrhosis of the liver and no mechanical blocking of the bile passages. The spleen was enlarged, but showed nothing microscopically except hyperplasia and hyperemia. The cortex of the kidneys showed a peculiar brownish color, which was shown microscopically to be due to the presence in the cells of the convoluted tubules of large quantities of pigment granules giving the iron reaction.

The exact nature of this peculiar disease is not clear. It is evident that it is not due to mechanical blocking of the bile passages, as the stools are always well colored, and even the urine may be completely normal. Certain French writers have advanced the idea that there is a low grade of angiocholitis due to mild infection of the bile passages. The single autopsy does not bear out this view. The fact that the blood always contains bile pigment and the constant involvement of the spleen suggests some disturbance of blood destruction as the cause of the condition. Minkowski suggests that the primary lesion may be in the spleen itself. Until our knowledge of the exact part played by the liver and spleen in blood physiology and pathology is more definite the true nature of the condition will probably remain obscure.

PROGNOSIS IN TUBERCULOSIS.

So much has been said in recent years of the curability of tuberculosis, if the disease is properly treated in the incipient stage, and of the confidence with which lasting improvement can be looked for, under favorable conditions, even in the more advanced cases, that a very salutary hopefulness has been inspired in both physicians and patients. This is of itself an excellent addition to any method of treatment. Of late, however, there are some signs of a reaction. At times physicians have seen their hopes fail of realization, even though patients have been faithful in following directions and though apparently they have been in the most favorable surroundings for a cure.

This has led many physicians to believe that the merits of the open-air, abundant food treatment are exaggerated, and this, like other methods of treatment, is destined to be a disappointment.

Perhaps the best antidote for this reactionary feeling is a frank consideration of the cases of tuberculosis which have not a favorable prognosis, even though the disease may not be far advanced when the patients come under consideration. It is comparatively easy to glean from recent literature the reasons why, in individual cases, the results from the open-air treatment are not satisfactory. Practically all agree that in patients in whom pulmonary tuberculosis has run a rapid course the outlook is seldom hopeful. If the history extends only over three months, and if there is considerable loss of weight, even though there be no cavity formation, and though not much of the lung be involved, the prognosis is never favorable. Such patients have little power of resistance against the tubercle bacillus and ultimately are almost certain to become its victims. Another class of cases in which the prognosis is always doubtful includes those patients with only mild lesions who present a rapid pulse. The tubercle bacillus seems especially to affect the pulse and, as a rule, does not cause much disturbance of temperature. A high temperature is generally due to secondary infection. Children with cold abscesses almost invariably have rapid pulse, though they generally have very little fever. If a small number of bacilli, therefore, are capable of so affecting the pulse, there is evidently a similar lack of vitality to that which exists in the cases which lose weight rapidly. It is a curious contradiction of what is usually considered to be the case that high temperature in tuberculosis does not necessarily indicate a bad prognosis. If a short walk sends the pulse up 30 points in a tuberculous patient, it may be assumed that the patient lacks resistive vitality. It has been pointed out also that the tendency of an individual to be normally under weight is an unfavorable symptom. A man who has all his life been twenty pounds under normal weight is almost certain to be especially susceptible to infection by the tubercle bacillus. As a rule, insurance companies prefer to take a man whose weight is normal, even though he has a family history of tuberculosis, rather than one who is under normal weight without any history of tuberculosis in his family.

---

[2] Clinical Society's Transactions, vol. xiii.

There are other symptoms in individual patients which, while not necessitating an unfavorable prognosis, always make the outlook more grave, even in the apparently favorable cases. Prof. Burney Yeo has pointed out that the most important climatic element for the cure of consumption is a daily variation in temperature of more than twenty degrees, which, he claims, acts on the organism in a way to produce a conservative reaction against further bacterial invasion.

There are some patients who can not stand such variations of temperature, however; they become so intensely uncomfortable under those conditions that their appetite suffers and, of course, a cure can not be expected when an abundance of food is not taken. Such patients, as well as those who have exaggerated catarrhal tendencies, so that variations of temperature cause them to have acute exacerbations of their tuberculosis and troublesome forms of bronchitis, will do best and live longest if sent to a mild, unvarying climate, such as is to be found in certain parts of the South. The most that can be hoped for from such climatic treatment, however, is a prolongation of life, not an enduring, absolute cure. These patients may be made very comfortable by such change of residence, but, as a rule, they will have to stay in their new homes the remainder of their lives, and probably the years left to them will not be many.

TRUTH AND POETRY CONCERNING URIC ACID.

III.

It has been seen how the hypothesis that uric-acid formation is due to an oxidation of albumin, which stops short of urea, gradually came to be discredited. The keen Salkowski, in 1870, had pointed out that if the uric acid in leukemia is due to faulty oxidation, other incomplete oxidation products must also be present. Those most likely to occur would be oxalic acid and allantoin, but careful studies of the urine in leukemia revealed no increase in these compounds. Salkowski, in 1871, therefore rejected Bartels' conception and inclined to view with favor Ranke's hypothesis that uric acid is derived from xanthin bases and the spleen. Against this was the observation that xanthin bases appeared to occur in only very minute quantities in the tissues, and, further, that feeding experiments made with xanthin on dogs (an unsuitable animal, as will be seen) caused no increase in uric-acid excretion.

About this time there developed that remarkable series of researches which led to our modern knowledge of the nucleins and their cleavage products—researches which, as they were destined to exercise an important influence on uric-acid studies, must here be briefly referred to. Miescher, in 1874, working on salmon sperm, had isolated nucleinic acid, and had shown that xanthin bases are formed when it is decomposed. Kossel, 1879, took hold where Miescher was all too early compelled to leave off, and showed that the xanthin bases, namely, xanthin, hypoxanthin, adenin and guanin can be obtained from nuclein; they are not present as free bases in the nuclein, but in organic union in the nucleinic acids. Kossel,[1] in 1881, immediately recalled the old ideas of Scherer and Ranke, and suggested again that the xanthin bases might be forestages of uric acid. The main argument to the contrary, as we pointed out above, had been the sparsity of xanthin bases in the tissues, but Kossel showed that if the organically combined bases be considered, the amounts present, especially in organs like the spleen, liver and kidney, are large. A year later[2] he emphasized in this connection two facts: (1) that the muscles of those animals (birds and reptiles), whose chief metabolic end product is uric acid, are much richer in hypoxanthin than those of mammals; and (2) that in leukemia the nuclein bases in the blood are increased. It is not surprising, therefore, that experimental feeding of the xanthin bases was again resorted to (Baginsky, 1883); but the results left the matter in doubt, and the problem was not to be easily solved.

An important paper by Stadthagen,[3] in 1887, reported experiments on the feeding of xanthin to dogs, with negative results, so far as an increase in uric acid was concerned. Stadthagen was of the opinion for a time that the nucleins of the food are split sometimes with formation of xanthin bases, at other times with formation of uric acid. He thought it possible that when xanthin bases are once formed from nuclein there can be no formation of uric acid. He therefore fed nuclein directly to dogs with the hope of finding the uric acid increased; the results were, however, negative, though Stadthagen suggested that this might be due to the fact that the nucleins of food are "dead" and may behave differently in metabolism from the nuclein of living cells. This investigator finally, apparently reluctantly, returned to the old view that uric acid is derived from albumin. His studies had led him to the belief that an origin from nuclein or xanthin bases can not be proved. It seemed to him positively demonstrated (1) that an increase of uric acid is absolutely dependent on the albumin-intake (irrespective of nuclein or xanthin bases), and (2) that uric acid. so abundant in children, must be derived in them from the casein of milk which contains no xanthin bases.

[3] Stadthagen: Ueber das Vorkommen der Harnsäure in verschiedenen tierischen Organen, ihr Verhalten bei der Leukämie und die Frage ihrer Entstehung aus den Stickstoffbasen, Arch. f. path. Anat., etc., Berl., vol. cix, 1887, p. 390.

The fallacy of Stadthagen's reasoning is obvious. In the first place, careful experiments have shown that uric-acid excretion is completely independent of the general nitrogen-metabolism.[4] Haig had asserted. it is true, that uric acid and urea are always formed in the same proportion (1:33); this view was entirely arbitrary in its origin, and Haig tried to explain the facts contradicting it by assuming that, when the proportion varies, the discrepancy is due not to differences in formation of uric acid, but to increase or diminution in the alkalinity of the blood, with correspondingly increased or diminished solubility and elimination of uric acid in the urine. Herringham and Davies, in 1891, showed that the excretion of uric acid varies independently of the blood alkalescence as determined by titration, and a year later Herringham and Growes stated that experiments proved that uric-acid excretion is independent of the ammonia excretion in the urine (which they regarded as a measure of the latent acidity). A review of the various experiments "after the event" shows that the investigators who found a definite dependence of uric-acid excretion on albumin-intake had used almost exclusively meat as food in the experiments; where other albumins were administered such dependence was not found to exist. In the second place, Stadthagen was wrong, as Wiener points out. in assuming that the formation of uric acid on a nuclein-free diet (such as milk fed to young infants) makes its origin from xanthin bases or nuclein impossible, for it has been proved that animal cells are capable of manufacturing nucleins from other nitrogenous substances,[5] and this synthesized nuclein may serve as a source of uric acid.

In 1888 Mares put forward the hypothesis that uric acid is a product of the activity of the cell-protoplasm, "of that chemical process which forms the basis of cell-activity." While urea, according to Mares, arises directly from the decomposed albumins of the food, uric acid, he thought, is formed only indirectly from the albumins of food, through gradual transformation of the organized albumins of the body cells.

The time had now come for a very important discovery. It had remained for Horbaczewski,[6] in 1889, to establish with certainty the direct relation of uric acid to the nucleins. He squeezed spleen pulp, mixed it with defibrinated blood, passed air through it and found that large amounts of uric acid are formed. He believed, therefore, that the forerunner of the uric acid exists in the spleen, and that this forerunner, probably nuclein or one of its cleavage products, yields uric acid on oxidation. Later he isolated nuclein from the spleen and prepared uric acid directly from it; in a similar manner he made uric acid from the nuclein derived from other organs, and these findings, with slight modifications, have been controlled and confirmed by Giacosa (1891), Spitzer (1899), and others. Horbaczewski next resorted to feeding experiments, using rabbits and human beings instead of dogs for the tests, and found an increase in uric acid two hours after the administration of nuclein. All subsequent observers confirm this origin of uric acid from nuclein.

In spite of the fact that Horbaczewski had made a very important discovery, he unfortunately soon strayed into a wrong path. He assumed, without adequate basis. that only the nucleins of leucocytes take part in uric-acid formation, and denied the direct relation of other nucleins to the substance. With this phase of the subject we expect to deal next week.

SOCIETY MEMBERSHIP AS A QUALIFICATION.

It is announced that a man of means is to build four hospitals along the line of a certain railway extending through four states. The general public is to be admitted to these hospitals, and may be under the care of any physician "who is a member of the state medical society." As the profession becomes better organized, it will be recognized in more and more lines of activity that membership in representative medical societies is a good indication of the standing of a physician.

CORRESPONDENCE SCHOOLS OF MEDICINE.

In addition to correspondence schools of nursing and of pharmacy, there are now schools which teach medicine by mail. It is bad enough to propose to teach nursing by correspondence; when it comes to medicine it seems that the limit has been reached. In view of the state laws, it is difficult to understand how students of medicine can be obtained by these "schools," unless the students are in the dark concerning the state regulations governing the practice of medicine. In the present condition of medical knowledge it is difficult in four years of personal contact with teachers for a student to equip himself fairly for the practice of medicine. And yet these correspondence schools are finding dupes, or it would not pay them to advertise.

A MEDICAL CONGRESS ON SHIPBOARD.

The misfortune which befell a party of physicians en route to the recent Pan-American Medical Congress at Panama, namely, the delay of the ship so that they were too late for the congress, did not prevent them from having a little congress of their own on board. It seems that the party sailed from Baltimore in what should have been ample time to reach Panama, but the weather was bad, fog prevailed, and the machinery broke. When the two-score physicians realized that they would miss all but the last day of the congress, they proved themselves equal to the emergency and held their own little congress on board the ship, and the pleasant sequel of their ability to meet this unusual situation was the acceptance by the Pan-American Medical Congress of their branch meeting as a part of the proceedings of the regular congress. A medical congress is not usually held on board ship, and hence this one had a particular zest and spice about it.

AN ANTICIGARETTE MOVEMENT IN SPAIN.

We learn from the *London Globe* that the government of Spain has had brought to its attention the evils of racial degeneration due to the excessive use of tobacco, especially by the young. The minister of the interior, it is said, has drafted a bill absolutely prohibiting the sale of tobacco, cigars or cigarettes to any person under 17 years of age, under penalty of fines of from $10 to $100 for each offense, and of imprisonment in aggravated cases. It is said that the youth of Spain, especially the working classes, are largely illy-nourished and of feeble constitutions, and that much of their scanty income is wasted on tobacco, thus keeping up and aggravating the evil. Tuberculosis makes great ravages among them, and the state of affairs is such that the government evidently thinks it full time to inaugurate a social reform to curb the evil, as far as the use of tobacco by the young is concerned.

WHEN ECONOMY AIDS HYGIENE.

When the requirements of sanitation and prophylaxis of disease demand additional expenditure of money by those who are interested in keeping down expense, sometimes regardless of other considerations, trouble ensues. There is then required a campaign of education and of enlightenment of the people and of the lawmakers so that proper legislation may be secured to enforce what may not be willingly done otherwise. We are much interested to note the report of the Central Railway of New Jersey, which has recently installed a system of car cleaning by the vacuum sweeping system. The dirt and dust is drawn from all the surfaces in the car by suction through a pipe. The work is done effectively, hygienically, and—a noteworthy fact—economically. The railroad management announces that this system reduces the cost of cleaning so that two cars can be thoroughly cleaned under the new system at the same expense of time and money as was formerly consumed in cleaning one. This fact, in connection with the increased sanitary value, is sure to cause a general introduction of this method within a short time, not only by other transportation companies, but by theaters, hotels and places of public resort.

THE HALL OF FAME.

The absence of the name of any physician in the Hall of Fame of the University of New York influences the editor of the *Western Medical Review* to remark that "it is the obvious duty, not only of physicians themselves, but of the public, to see to it that in the election this year not less than three physicians are selected." The editor proceeds to recommend Benjamin Rush, David Ramsay, John Collins Warren, J. Marion Sims, Oliver Wendell Holmes. Under the rules, only persons born in the United States, now dead ten years or more, and most eminent in their respective fields, are eligible for nomination. The original plan was to select names for fifty of the 150 panels in 1900, and five more every five years thereafter until the list would be completed in 2000. In 1900, out of 252 nominations made, only twenty-nine received the required majority (51) of the votes cast and were elected. This makes twenty-six to be selected this year. If the medical profession really wishes some of its illustrious men to be elected, the proper procedure, we suggest, is to place the matter in the hands of a committee, who will acquaint the members of the Council of the University of New York with the claims to greatness of certain physicians, so the vote on the nominations by the members of the council may be made with full knowledge concerning the medical candidates.

THE DEVELOPMENTAL OR MYELINOGENETIC REGIONS OF THE HUMAN CEREBRAL CORTEX.

A few years ago Flechsig interested neurologists greatly by his subdivision of the cerebral cortex into primary sense centers on the one hand and association areas on the other. Since that time he has been busily engaged in the further differentiation of the cortex on the basis of successive medullations of the fibers. He now recognizes between thirty and forty definite and distinctly different myelinogenetic regions. He thinks that each myelinogenetic region is provided with a conjugate pair of bundles, one bundle bringing impulses to the area, the other carrying impulses from it. A further view advanced by Flechsig concerns the close relation of the development of the sulci of the brain to that of the medullary sheaths of the various bundles going to the different areas. He distinguishes primary sulci, those which appear very early, from terminal sulci, which are the last to develop. The earliest sulci appear, he asserts, where the brain "ripens" first, while the latest sulci to appear correspond to areas of the cortex, the fibers of which become medullated late. In how far these views of Flechsig will be confirmed by other investigators can not yet be determined. His earlier statements concerning the association centers have been severely criticized by Dejerine, Hitzig and others. Bianchi agrees with Flechsig in as far as he recognizes that the anterior portion of the frontal lobes are devoid of projection fibers and are concerned wholly with processes of association.

Medical News.

DISTRICT OF COLUMBIA.

Health of the District.—The report of the health officer for the week ended January 14 shows the total number of deaths to have been 121, of which 78 were white and 43 colored. There were 109 births, of which 74 were white and 35 colored. At the close of the week there were under treatment 22 cases of diphtheria, 30 of scarlet fever, 118 of typhoid fever and 2 of smallpox.

Woman's Clinic Election.—At the annual meeting held January 4 the following officers were elected: President, Dr. E. L. Ragan; vice-president, Dr. Robert Reyburn; treasurer, Mary F. Case; secretary, Miss E. Clarke. Clinical staff—Drs. Ida J. Heiberger, Phoebe R. Norris, A. F. Faye, Ada R. Thomas, Mary L. Stroble, B. Rosalie Slaughter, Anna Bartsch and Robert S. Lamb. Consulting staff—Drs. H. L. E. Johnson, Mary Parsons, James F. Scott, Edward A. Balloch, George N. Perry, Albert L. Stanley and Randolph B. Carmichael.

Medical Society Election.—At the annual meeting of the Medical Society of the District of Columbia, held January 2, the following officers were elected: President, Dr. T. N. McLaughlin; vice-presidents, Drs. John D. Thomas and Murray G. Motter; corresponding secretary, Dr. Thomas C. Smith; recording secretary, Dr. Francis P. Morgan; treasurer, Dr. Charles W. Franzoni, and librarian, Dr. Edwin L. Morgan. At the meeting held January 11 Dr. James J. Walsh of New York addressed the society, and a smoker was afterward held at which he was the guest of honor.

ILLINOIS.

Influenza Epidemic in Peoria.—Peoria is said to be suffering from one of the most severe attacks of influenza in its history. More than 2,000 cases have been reported and the disease is spreading rapidly.

Hospital Staff Warned.—In his introductory remarks to the newly-appointed members of the Cook County Hospital staff President Bundage of the county board said:

> You have been selected as members of the county hospital staff without pull, political or otherwise. I want you to understand that if you *do* not live up to the rules governing the institution no pull of any kind will stand in the way of your resignation being asked for.

Chicago.

Professor Barker Appointed to a Professorship of Medicine.—The board of trustees of Rush Medical College has appointed Dr. Lewellys F. Barker to a professorship in medicine in that institution.

Mortality of the Week.—There were 591 deaths during the week ended January 21, equivalent to an annual death rate of 15.47 per 1,000. Pneumonia heads the list with 120; consumption follows with 79; Bright's disease with 51; heart disease with 37; violence with 35, and influenza with 22.

Honor Memory of Dr. Mary Harris Thompson.—On January 30 will be unveiled at the Art Institute with appropriate ceremonies the portrait bust of Dr. Mary Harris Thompson, done by Daniel French, which club women and other friends of Dr. Thompson are presenting to the Art Institute.

Decline of Tuberculosis.—In the Bulletin of the Department of Health the following record is given of the decline of consumption mortality:

> In the decade ended 1860 the annual deaths from consumption averaged 29.57 per 10,000 of population; in the decade ended 1870 they averaged 20.47; in 1880, average 16.74; in 1890, average 17.56; in 1900, average 15.89—a reduction of 46.2 per cent. in fifty years. In 1901 the rate was 14.19; in 1902 it was 14.04—the lowest point yet reached, and less than one-half the average of fifty years previous.

MARYLAND.

Recognition of Services.—Dr. John S. Fulton, secretary of the State Board of Health, has been presented with a handsome silver tea service in recognition of his services in the cause of public health. A letter signed with the names of the donors—physicians and others—accompanied the gift.

Talbot County Medical Society has elected the following officers: President, Dr Julius A. Johnson, Easton; vice-president, Dr. James A. Stevens, Oxford; secretary and treasurer, Dr. Philip L. Travers, Easton; delegate to state society, Dr. E. R. Trippe, Easton; and censors, Drs. Samuel C. Trippe, Royal Oak; Joseph S. Garrison, Easton, and Charles H. Rose, Cordova.

Affairs at the University of Maryland.—At the annual meeting of the General Alumni Association, January 18, Wilmer Brinton was elected president, and Dr. Eugene F. Cordell secretary-treasurer and chairman of the endowment committee. A university button was adopted and an address was delivered by Dr. Thomas Fall, president of St. John's College, Annapolis, advocating the establishment of a State University. A committee of five members was appointed to consider the matter and also a union of the university and St. John's College. Dr. Eugene F. Cordell has founded a university monthly, the name of which is "Old Maryland." On the editorial staff are Dr. R. L. Mitchell, medicine; D. W. Burroughs, law; J. Clarence Allen, dentistry, and C. W. Hornbrook, pharmacy.

Baltimore.

School Inspection.—The medical inspection of public schools will begin February 1, Drs. R. Tunstall Taylor and I. R. Page having been appointed inspectors.

Personal.—Dr. John C. Hemmeter has been elected a foreign member of the Deutsche Gesellschaft für Innere Medizin.——Dr. William Lee Howard has gone to Jamaica.——Dr. M. M. Whitehurst has gone to Mexico and California.

For Isolation Hospital.—Health Commissioner Bosley hopes to secure a municipal infectious disease hospital on city property near Bayview Asylum. The board of estimates has allowed him $1,000 to commence the medical inspection of schools.

Surgeons for Confederate Veterans.—The Isaac R. Trimble Camp, No. 1025, United Confederate Veterans, elected the following medical officers: Surgeon, Dr. John H. Grimes; assistant surgeons, Drs. Alex. L. Bell, James G. Wiltshire and Louis W. Knight.

Deaths of the Week.—For the week ended January 21, there were only 167 deaths reported, a singularly low mortality. This was a rate of 15.22 per 1,000, or, according to color, for the white, 12; colored, 32.65. Pneumonia and consumption led, each causing 27 deaths.

Vital Statistics.—According to the annual report of the Health Commissioner for 1904, there were 10,818 deaths; males 5,654, females 5,164. The death rate per 1,000 was 19.26 (white, 17.02; colored, 31.44). There were 8,599 births reported—males, 4,444; females, 4,155. The principal causes of death were pulmonary tuberculosis, 1,349; pneumonia, 1,121; heart disease, 815; Bright's disease, 749; diarrhea, 743; cancer, 450, and apoplexy, 381.

Association Election.—At the annual meeting of the Baltimore Medical and Surgical Association, January 9, the following were elected to office: President, Dr. C. Urban Smith; vice presidents, Drs. Charles O'Donovan and Nathan Winslow; secretary, Dr. Eugene L. Crutchfield; treasurer, Dr. W. B. Perry; executive committee, Drs. James M. Craighill, Arthur Hebb, and D. Streett; and committee of honor, Drs. John Neff, John W. Linthicum, and John I. Pennington. After the election of officers a banquet was served.

MICHIGAN.

Anti-Spitting Law in Lansing.—The first conviction under the new anti-spitting ordinance in Lansing occurred January 17, when Perry Boughner was found guilty of spitting on a sidewalk.

Prescott Critically Ill.—It is reported that the venerable Prof. Albert B. Prescott, dean of the school of pharmacy and senior professor in the University of Michigan, is critically ill with pneumonia.

Cushny Goes to London.—It is announced that Dr. Arthur R. Cushny, professor of materia medica and therapeutics in the University of Michigan, has resigned to accept a similar chair in the University of London, England.

Academy Elects Officers.—The annual meeting of the Kalamazoo Academy of Medicine was held January 12, at which the following officers were elected: President, Dr. John Bosman, Kalamazoo; vice-presidents, Drs. Wilbur F. Hoyt, Pawpaw, and Edward P. Wilbur, Kalamazoo; secretary-treasurer, Dr. Walter den Bleyker, Kalamazoo; librarian, Dr. Edwin H. Van Deusen, Kalamazoo, and censors, Drs. Harris B. Osborne and Ralph E. Balch, Kalamazoo.

NEW YORK.

Site for State Hospital.—The State Lunacy Commission has accepted the Baker site for a new state insane hospital in Washington County.

County Society Honors Dead.—The eighty-fourth annual meeting of the Erie County Medical Society was held January 10. Dr. William C. Krauss, president, was in the chair. Memorials on the following deceased members were read, as follows: Dr. J. G. Thompson, by Dr. N. W. Wilson; Dr. H. S. Ingraham, by Dr. W. C. Phelps; Dr. R. S. Meyers, by Dr. Henry Lapp; Dr. S. Lynde, by Dr. G. W. Wende, and Dr. A. T. O'Hara, by Dr. Edward Clark. The board of censors presented a caustic report on the medical criminals—abortionists, fakers, mediums, and advertisers—of Erie County.

New York City.

Personal.—Dr. Livingston Farrand, professor of anthropology at Columbia University, has been named as head of the National Association for the Study and Prevention of Tuberculosis.

Decrease in the Death Rate.—Reports show that there has been a decrease in the death rate in this city of 2.8 per cent. as compared with the same week of last year. The conditions throughout the city are better than they were at this time a year ago.

Change in Bulkley Lectures.—Dr. Bulkley's usual clinical lecture at the New York Skin and Cancer Hospital will be replaced February 1 by a lecture by Dr. Boleslaw Lapowski on the "Treatment of Syphilis," and on February 8 by a lecture by Dr. Charles Mallory Williams on the "Treatment of Acne."

New Ophthalmic Institute Site.—At the annual meeting of the New York Ophthalmic and Aural Institute it was announced that the trustees and their friends had collected $200,000 toward the erection of a new building and that a site had been purchased at 64th Street and Central Park. Ground will not be broken until $350,000 has been raised.

Orthopedic Hospital.—The report of this institution presented at the annual meeting shows a prosperous condition. A standing deficit of $22,000 was wiped out, although running expenses were $7,000 greater than the income. During the year 4,017 cases were treated, and a country branch and industrial school was opened at White Plains for convalescents.

The Work of the Milk Commission.—The milk commission of the Medical Society of the County of New York has distributed a notice to its members, calling attention to the fact that, while it has supervision of only that portion of a dealer's milk which carries its certification, it does not intend to allow a dealer known to have adulterated milk to sell certified milk.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending January 14, 338 cases of tuberculosis, with 160 deaths; 307 cases of diphtheria, with 43 deaths; 281 cases of scarlet fever, with 17 deaths; 202 cases of varicella; 189 cases of measles, with 6 deaths; 56 cases of typhoid fever, with 9 deaths, and 26 deaths from cerebrospinal meningitis.

Memorial to Dr. Skene.—The sum of $5,000 has been given anonymously to the Kings County Medical Society for the founding of the Alexander J. C. Skene Memorial Fund. Dr. Skene was a former president of the society. The conditions of the fund are that the income from it shall be devoted to the purchase of books and journals relating to Dr. Skene's specialty—obstetrics and gynecology.

NORTH DAKOTA.

Appointments.—Dr. Edward M. Darrow, Fargo, as member Cass County Board of Insanity.——Dr. George A. Carpenter, Fargo, as superintendent of Cass County Board of Health.——Dr. John D. Henning, Fargo, as physician of Cass County.——Drs. F. B. Strauss, Glen Ullin, and George A. Stark, Mandan, physicians for Morton County.

Proposed State Laboratories.—Dr. J. D. Taylor of Grand Forks introduced a bill in the legislature providing "for the creating of a state bacteriologic and pathologic laboratory, for the control of such laboratory, and duties of the director, for the appointment of a director of such laboratory who shall be ex-officio state bacteriologist, and for an appropriation for the support of such a laboratory."

OHIO.

New Hospital Open.—The new hospital at East Liverpool was informally opened, January 2. It has been built wholly by private subscription.

Springfield Hospital Ready.—On December 29 the new City Hospital, erected at a cost of about $100,000, was formally opened. The staff has elected the following officers: Dr. John M. Buckingham, president; Dr. Bennetta D. Titlow, vice-president, and Dr. Jay D. Thomas, secretary and treasurer.

Society Election.—At the annual meeting of the Fairfield County Medical Society the following officers were elected: President, Dr. W. Stanley Samson, Lancaster; vice-president, Dr. George P. Haddell, Stoutsville; secretary, Dr. Henry R. Plumb, Lancaster; treasurer, Dr. John H. Axline, Lancaster, and censor, Dr. T. R. Mason, Sugar Grove.

Gift of Hospital.—Mr. J. F. Pocock has presented to Massillon a general hospital to be controlled by the Massillon Hospital Association, with a capital stock of $50,000. He has given a lot on which he will have erected suitable fireproof buildings, thoroughly equipped and furnished, all of which he will turn over to the city as a gift.

Personal.—Dr. August Schumacher, Hamilton, has succeeded Dr. Thomas D. Sharkey as coroner of Butler County.——Dr. Dan Millikin has been elected president of the Board of Education of Hamilton.——Dr. Kent B. Waite, Cleveland, has been adjudged insane and taken to the state hospital, Newburg.——Dr. Robert C. Chamberlain, Tiffin, has been appointed physician to Seneca County Infirmary.——Dr. Josiah Medbery, Columbus, has recovered from his recent operation and has resumed his work.

Cincinnati.

Deficit Does Not Alarm.—The deficit at Christ's Hospital for the year just ended will be about $1,600. Inasmuch as the hospital has used $15,000 for its charity work alone, this deficit is not regarded with alarm.

Hospital Directors Organize.—The Board of Medical Directors of the Cincinnati City Hospital has organized and elected Dr. Asa B. Isham, president; Dr. Louis Schwab, vice-president, and Dr. Byron Stanton, secretary.

Corpses Transported in Passenger Coaches.—The transportation of corpses in the smoking compartments of passenger cars of the Rapid Railway is to be fought by the newly-created Kennedy Heights Board of Health. Communications have been opened with the State Board of Health to see if the company has the right to carry corpses in the regular passenger cars.

Personal.—Dr. Otis L. Cameron has been appointed coroner, and Dr. Oliver L. Coe, deputy coroner, of Hamilton County.——Dr. Stephen E. Cone, secretary of the Academy of Medicine, has resigned, and Dr. Samuel Iglauer has been appointed temporary secretary.——Dr. James W. Miller has been appointed district physician vice Dr. William Muhlberg, resigned. He was appointed examining physician January 14, and Dr. Henry W. Albers appointed district physician in his stead.——Dr. Thaddeus A. Keamy was presented with a loving-cup on January 12 by the Beta Theta Pi fraternity.——Dr. Arthur Vos, house physician to the Cincinnati Hospital, is suffering from septicemia.

PENNSYLVANIA.

Erie County Medical Society, at its annual meeting in Erie, elected the following officers: President, Dr. George B. Kalb; vice-president, Dr. Thomas Purcell; secretary, Dr. Adella B. Woods; treasurer, Dr. George S. Ray; library committee, Drs. David N. Dennis, James H. Montgomery and Ira J. Dunn; censors, Drs. James E. Silliman, Frank A. Walsh and Ira J. Dunn, and reporter, Dr. Guy C. Boughton.

Hospitals at Steel Mills.—The great increase in accidents in the mills of the United States Steel Corporation have led the officials of the company to take steps toward the erection of two emergency hospitals in their mills at Donora. Previously all men injured had to be conveyed to the hospitals of Pittsburg or McKeesport before their injuries could be properly treated and their true character determined.

Mine Accidents.—From official information of the mine inspectors of the four anthracite districts in the Wyoming Valley it is shown that in all 537 men and boys were killed or injured during 1904. There were 199 fatal and 338 non-fatal accidents in the districts, leaving 109 women as widows and 212 children, orphans. In the tenth anthracite district an official report shows there were 37 fatal and 54 non-fatal accidents, an increase of 85 per cent. over the preceding year. These accidents left 19 widows and 44 orphans.

Society's Annual Meeting.—The Northampton County Medical Society held its fifty-sixth annual meeting in Easton, January 20. The following officers were elected: President, Dr. George N. Schwartz, Pen Argyl; vice-presidents, Drs. Arthur D. Reagan, Easton and Harry C. Pohl, Nazareth; secretary, Dr. James J. Quincy, Easton; corresponding secretary, Dr. John E. Fretz, Easton; treasurer, Dr. Joseph S. Hunt, Easton; reporter, Dr. James J. Quincy, Easton; censors, Drs. Edgar M. Green, W. H. Duler and H. J. Lacier, and delegate to state society, Dr. Henry D. Michler, Easton.

Care of Tuberculous Sick.—The Philadelphia County Medical Society, at its meeting January 18, adopted the following resolutions:

> WHEREAS, The state of Pennsylvania has not up to the present time provided adequate accommodation for the care and treatment of its tuberculous sick; and
>
> WHEREAS, The plans now in projection throughout the state, even when successfully executed, will provide for but a mere fraction of the number of those who need skillful care and medical direction, both for the saving of their lives and the protection of the community; and
>
> WHEREAS, Experience has shown that by properly directed open-air treatment the great majority of cases of incipient tuberculosis can be permanently cured, and that a large percentage of the daily new infections can be avoided if such patients are removed from close association with others not yet infected; be it
>
> *Resolved*, That the Philadelphia County Medical Society does hereby petition the legislature of the state of Pennsylvania:
>
> 1. For the appropriation of a certain sum of money, not less than $500,000, to be devoted to the establishment of camps, sanatoria, hospitals and dispensaries, for the tuberculous sick of the commonwealth of Pennsylvania.
> 2. For the setting aside of such portions of the State Forestry Reserve as may be recommended with a view to accommodating camps and buildings, such as may be deemed necessary for the care of tuberculous patients, and for their scientific study and treatment; further be it
>
> *Resolved*, That the president of this society be authorized and instructed to appoint a committee of three from the membership of the society to co-operate with similar committees that may be appointed from other societies in urging on the legislature the need of state aid in the suppression of tuberculosis.

Philadelphia.

Women's Hospital Report.—During last year there were 1,217 patients admitted, making a total of 1,281 patients treated. There were 20,000 cases treated in the clinics and 201 births in the maternity.

Jewish Hospital Staff.—The following physicians were elected to the staff of the hospital: Dr. Charles P. Noble, consulting surgeon; Dr. Lawrence F. Flick, consulting surgeon; Dr. William H. Randle, obstetrician; Dr. Joseph B. Potsdamer, pediatrist, and Dr. Sidney L. Feldstein, radiologist.

Talk on Consumption.—Efforts are being made by the Henry Phipps Institute to educate the textile workers of the city as to the danger of spreading consumption and the means of combating its propagation. A series of lectures will be delivered to the textile workers of Kensington by members of the staff of the Henry Phipps Institute on the home treatment of the disease, beginning January 30.

Chicagoan in Philadelphia.—Dr. Robert B. Preble, professor of medicine in the Northwestern University Medical School, will address the students of the Jefferson Medical College in the college building, February 1, under the auspices of the H. A. Hare Medical Society, on "The Extra-Pulmonary Localization of the Pneumococcus." He will be tendered a reception by the society immediately after the address.

Clinical Assistants Organize.—On January 4 the Association of Clinical Assistants of Wills Hospital was organized, with the object of bringing together all who have served in this capacity in the hospital for the informal discussion of ophthalmic subjects. Dr. S. H. Brown was elected secretary-treasurer, and an executive committee was elected, consisting of Drs. John T. Krall, Josephine P. U. Hildrup and S. H. Brown.

Health Report.—The total number of deaths reported for the week was 519, an increase of 19 over the preceding week and a decrease of 99 from those of the corresponding week of last year. Eighty-three deaths were due to acute inflammation of the respiratory tract, 12 to typhoid fever, 62 to pulmonary tuberculosis, 23 to cancer, 25 to apoplexy, 51 to heart disease, 11 to enteritis and 37 to Bright's disease. There were 236 cases of contagious disease reported, with 24 deaths, as compared with 222 cases and 24 deaths for the previous week. No smallpox was reported.

Oncologic Hospital Open.—The American Oncologic Hospital, the first institution in the country to be devoted exclusively to the study and treatment of cancer, was formally opened January 4. Dr. G. Betton Massey made the opening address. Both charity and pay patients will be admitted and it is the purpose of the staff to employ all methods of treatment that promise to be of service in this class of cases, including electrochemical sterilization and radiotherapy. Dr. Boardman Reed is attending physician, and Drs. Addinell Hewson, G. Betton Massey and Howard R. Swayne are the attending surgeons.

Medico-Chirurgical Alumni Election.—The alumni association of the Medico-Chirurgical College has elected the following officers: President, Dr. William L. Shindle; secretary, Dr. Stilwell C. Burns; treasurer, Dr. Emanuel S. Gans, and executive committee, Drs. W. Easterly Ashton, Arthur E. Blackburn. Arthur C. Buckley, L. Napoleon Boston, Joseph A. Cramp, John W. Croskey, Morton P. Dickeson, John H. Egan. L. Webster Fox, Andrew Godfrey, Charles H. Gubbins, S. Leon Gans, A. Wiese Hammer, W. Frank Haehnlen, Harry Lowenbury, Francis Lemmer, John A. McGlinn, John A. McKenna, George W. Pfromm, Joseph V. C. Roberts, Herbert J. Smith, John W. Shoemaker, Mitchell P. Warmuth, John W. Wilkins and J. L. Widmyer.

Bequests and Donations.—By the will of Selina Walker the Jewish Hospital Association receives $7,286.73, and the Jewish Maternity Hospital, $2,428.90.——By the will of the late Francis T. Fassitt $5,000 is bequeathed to the Children's Hospital for the establishment of a free bed, to be known as the Anne Avoir Fassitt bed.——The will of Adolph Heinman bequeaths $500 to the Jewish Hospital and $350 to the Jewish Maternity.——By the will of William McFatrick, on the death of his wife and sister, the remainder of the estate, valued at $62,800, will be divided among the Presbyterian, Episcopal, Jewish, Methodist and Howard hospitals for the establishment of free beds. The will also requests the widow to donate an amount sufficient to establish a free bed in St. Agnes' Hospital.——By the will of Margaret Sullivan $200 is donated to St. John's Orphan Asylum.——Benjamin Tousey of Syracuse, N. Y., has donated $5,000 to the University of Pennsylvania Hospital to endow a free bed for the use of employes of the Central News Company.

GENERAL.

Government Laboratory Building in Use.—A part of the new building for the Bureau of Government Laboratories, Manila, P. I., has been completed, so that a number of the branches have moved into their departments.

Panama Service Examination.—The examinations by the United States Civil Service Commission were held January 18, as announced in THE JOURNAL, Dec. 17, 1904, to select eligibles for service under the Isthmian Canal Commission. The attendance of physicians was not very large in many cities. In St. Louis there were twelve.

Health Report of the Philippine Islands.—The report of the Board of Health of the Philippine Islands and the City of Manila for September, 1904, states that 797 births were registered during the month. This is the largest number ever registered in any one month and gives a birth rate of 44.11 per thousand. During September there were 1,146 deaths in the city of Manila; of these 1,064 were residents and 82 transients. Fifty-four per cent. of all deaths occurred in children under one year of age, the number of deaths from infantile convulsions being 367. There were 5 cases of smallpox, with 2 deaths. One death from bubonic plague was registered. There were 96 deaths from tuberculosis and the same number from chronic diarrhea and enteritis.

CANADA.

Ontario Medical Association.—The annual meeting of this association will be held in Toronto, June 6-8, 1905, under the presidency of Dr. William Burt of Paris, the secretary being Dr. Charles P. Lusk, Toronto. Mr. I. H. Cameron is chairman of the committee of arrangements, and Dr. Alexander Primrose is chairman of the committee on papers and business. Dr. Ochsner of Chicago will deliver the address in surgery.

Northwest Territory Laboratory.—The government of the northwest territories of Canada is establishing a new bacteriologic and pathologic laboratory and has appointed Dr. George Charlton, formerly of the McGill University pathologic department, chief of the laboratory. Dr. Charlton will at first investigate swamp fever in horses, which die very rapidly once they contract this disease. Later he will investigate diphtheria and typhoid epidemics.

Canadian Medical Association.—The thirty-eighth annual meeting of the Canadian Medical Association will be held at Halifax, Nova Scotia, Aug. 22-25, 1905. Dr. John Stewart, Halifax, is the president, and Dr. George Elliott, Toronto, general secretary. The address in surgery will be delivered by Mr. Francis Caird of the Royal Infirmary, Edinburgh, while

Dr. Howard Kelly, Baltimore, will deliver the address in gynecology. Dr. J. W. Stirling, Montreal, will deliver an address in opththalmology, and there will be in addition addresses in medicine and in pathology. Dr. A. J. McCosh, New York, will also be asked to contribute a paper. The Medical Society of Nova Scotia will act as host to the Canadian Medical Association, and, therefore, will not hold its regular annual meeting.

Physicians Scarce in Newfoundland.—In the small settlements along the remote stretches of the Newfoundland coast there is lack of medical attendance. It is not uncommon for a physician to travel 100 miles by boat—there are no roads—to attend a patient. In many places the duties ordinarily fulfilled by a physician are performed by some man or woman who has picked up a little medical knowledge. The result in increased mortality statistics may be imagined. The government of Newfoundland is endeavoring to remedy this by appointing physicians or surgeons to the magistracies in the different townships. In the sparsely settled districts an allowance of $500 a year is made to a medical man who will settle there, on condition that he will undertake magisterial duties in addition to his professional ones. The former are not very onerous, usually having to do with fishery disputes, settlements and the like, for serious crime is unknown, and the other representative of the law is what is called a local constable, a person who acts for $2 a week in the capacity of process server and census enumerator.

FOREIGN.

Plague in Russia.—Plague has appeared in one of the Ural districts and has made rapid progress among the Kirghiz and cossack population. The epidemic of cholera in the Caucasus region has almost died out.

German Red Cross Mission to the Seat of War.—Professor Henle of Breslau is in charge of a Red Cross expedition from Germany to Japan. It was expected to sail from Genoa, January 15. Dr. Fittig and a trained nurse accompany the expedition. The rest of the personnel is to be supplied by the Japanese government.

Public Care for Tuberculous Children.—The new sanatoria in Germany are being constructed with a view to having a department for tuberculous children. The sanatorium near Hagen has made arrangements to board children under 14 during the winter months when lung trouble is suspected. The city of Charlottenburg has found the "school in the woods" such a success for weakly children that a second one is now planned. They are in the country, but close to the city limits, accessible by trolley.

The Madeira Sanatoria.—The first one of the sanatoria erected on the Madeira islands by German private enterprise, under the leadership of the Prince von Hohenlohe, has been formally inaugurated. It is at an elevation of nearly 1,000 feet, and has accommodations for sixty guests. It is planned to have accessory stations at various elevations higher up on the mountains, to determine the most favorable altitude for individual cases. The particulars of this new health resort were mentioned in the news columns of The Journal of April 2, 1904, page 903. Pannwitz, Rumpf, B. Fränkel, Wolf and Römer are among the physicians on the board of directors.

Progress of Cremation.—The number of cremations in France during 1904 was only 350, almost all at Paris. The crematory at Rheims has been ready for operation for more than two years, but not a single application has been made for cremation. In Germany the record of cremations for 1903 was less than 1,100, while in England the number was only 500. In Italy there were 400 cremations, and about the same number in Sweden and 300 in the Argentine Republic. The *Semaine Médicale* comments on these figures that cremation is not making much progress elsewhere than in the United States and in the Orient, where it has always been frequently employed. It cites at 4,000 to 5,000 the number of cremations in this country.

Report on Ankylostoma.—The committee appointed by the British Association for the Advancement of Science has made a preliminary report concerning ankylostoma, which is thus summarized by *Science:* There are many channels by which ankylostoma might be introduced into British coal mines. The conditions found underground in these mines are such that the worm would, in many cases at any rate, probably become firmly established. In view of the expense and difficulty of eradicating the worm from any mine in which it has become established it is of the greatest importance that preventive measures should be undertaken without delay. Complete eradication does not yet appear ever to have been accomplished. The necessary prevention is best accomplished by the provision of proper sanitary accommodation in the main roads underground and at the pit's mouth, by regulations to prevent pollution of the pit by human feces, and by the establishment of a limited quarantine system for work people from infected areas, with compulsory notification of cases to the home office.

School Contagion of Infectious Diseases.—M. Cohn is medical school inspector at Charlottenburg, and he has been studying the statistics of the four largest cities of Germany during the last ten years to learn whether infectious diseases are more prevalent or less so during the school vacations. If they are less prevalent at this time, it would be an argument in favor of closing the schools at the outbreak of an epidemic. He finds that the vacations do not seem to have any effect on the prevalence of diphtheria and scarlet fever. Measles, on the other hand, drops abruptly so soon as the schools close for a vacation. He explains this by the fact that scarlet fever and diphtheria are not so contagious in the early stages. The child is usually so sick that it is kept at home before the really contagious stage is reached. In measles the disease is highly contagious from the start, and he recommends to close the school room at once whenever measles is prevalent among the scholars. In the discussion which followed his address on the subject at the meeting of the German Public Health Society, December 6, the leading medical authorities reiterated that a child who has had scarlet fever should be kept at home for six weeks at least if transmission by way of the school is to be avoided.

Approaching International Anti-Tuberculosis Congress.—The French prime minister has asked for an appropriation of $20,000 for the approaching International Anti-tuberculosis Congress to be held at Paris in October of this year. The committee of organization comprises Casimir-Périer, ex-president of the republic, and L. Bourgeois, former prime minister, with Berthelot as acting president of the congress, and Chauveau, Herand and Brouardel as vice-presidents. The chairman of the section on medical pathology will be Bouchard, while Lannelongue will be chairman of the section of surgical pathology, Grancher of children's diseases, and Landouzy of the section for care and aid for the adult tuberculous. M. Letulle has been appointed secretary general of the congress and P. Masson, treasurer. Among the addresses already promised are some on the "Treatment of Lupus," "Early Diagnosis of Tuberculosis," "Comparative Study of Various Tuberculoses," "Ileocecal Tuberculosis," "Operative Treatment of Tuberculosis of Meninges and Brain," "Etiologic Factors,." and studies of sanatoria, etc. June 30, 1905, is the latest limit for the reception of communications. A tuberculosis exposition is planned in association with the congress. The exhibition will be arranged in two sections, a scientific and an industrial section.

Legislation Against Irregular Practices in Baden.—The bill to restrict quack practices, introduced into the Baden legislature, was described in The Journal of March 19, 1904. As finally adopted, the drastic measures first proposed were somewhat modified, but even under these circumstances the measure is regarded as a great advance in the protection of the public against irregular practices. Dr. Neustätter of Munich describes in the *Münchener med. Wochenschrift* of December 20 the history of the bill on its way through the upper and lower houses as extremely characteristic. The representatives of the people in congress assembled always seem to shrink with infinite dread from inflicting the slightest harm on the irregular practitioner. This is easily understood, he remarks, from the lay standpoint. It is impossible for laymen to believe that any one could be so dastardly as to play with the lives and the health of his fellow-men. This idea is remarkably firmly rooted in the popular mind. It is not shaken even by the testimony of facts which teach the contrary. The bill forbids extravagant statements in advertisements and "absent treatment." The latter clause is the first restriction of the kind, he adds, adopted by any state. Advertisement of aphrodisiac and anti-conception measures is likewise prohibited, as is also the case in Hamburg and Berlin. It is forbidden to advertise remedies which can not be sold without a physician's prescription. The bill is original in several points and not a mere imitation of what other states have adopted. It was prepared by the Carlsruhe board of health and its chairman, the mayor, with the co-operation of the local physicians.

Health Statistics of Malta.—The *British Medical Journal* states that a comprehensive scheme for the drainage of the large towns and principal villages in the two islands has been drawn up, and the work is being carried out as rapidly as the resources of the government will permit. The drainage of the three cities is now practically completed, and that of the large suburbs of Sliema and St. Julian's is well advanced. The population on March 31 last was estimated at 197,070, and the number of births registered during the year was 7,173, representing a general birth rate ot 37.69 per mille. The general state of public health is recorded as "good," though it is stated that the percentage of deaths among children under 5 years of age was 51.8, and that the general death rate was 24.45 per mille. Zymotic diseases accounted for 288 deaths, or 5.7 per cent. of the total number of deaths. Two outbreaks of smallpox occurred, the disease having been imported in the one case from Tunis and in the other from Sicily, but in neither did it assume serious importance, though out of the 50 cases recorded 10 died. The mortality from diphtheria seems to be exceedingly high, the disease proving fatal in 57 cases out of the 124 attacked. No statistics, unfortunately, are given with regard to Malta fever, it being merely recorded that there were 706 cases of "fevers" and 99 deaths. The climatic conditions of the year were peculiar, the summer months being unusually cool, and the rainfall for the year reaching a total of only 14.695 inches, some 10 inches below that of the preceding record.

The Suit Against the Gelsenkirchen Waterworks.—The famous suit brought by the state against the directors of the waterworks supplying a district in Germany in which an epidemic of typhoid fever broke out, has ended in the condemnation of the defendants to a fine and the costs of the suit, which are in the neighborhood of $25,000. The prosecuting attorney (*Staatsanwalt*), in closing his address, remarked that the twenty-two days during which the suit had lasted to date had accomplished more in the way of promoting public health and sanitation than twenty-two years under ordinary circumstances. There were probably 5,000 cases of typhoid during the epidemic, with 9 per cent. mortality in the 3,235 officially reported cases. It was established that nearly all these cases occurred in a district in which the water supply was clandestinely augmented during dry seasons by a pipe bringing unfiltered river water into the supply. This pipe was opened usually the last three days of the week during the summer, but was closed up at other times. When the epidemic broke out and the existence of the side pipe became known to the authorities, it was walled up and the entire pipe system of the waterworks, 300 kilometers in length (about 186 miles), was disinfected with sulphuric acid. About 15,000 quarts of 60 per cent. sulphuric acid were poured into each of the reservoirs until the desired concentration of 1 per 1,000 was reached. The entire faucet system was tied up for eight or nine hours. This was done September 29, and scarcely a single new case developed after October, the epidemic subsiding as abruptly as it had begun early in September. The indictment against the directors of the waterworks was at first that they had induced the epidemic by willful use of unfiltered river water in the side pipe mentioned above. The authorities found that they were unable to prove this indictment, as a leak in the main pipe had occurred in July, and as there was a possibility of other sources of contamination, consequently the indictment was changed to an accusation of the adulteration or falsification of food, and under this caption the directors were condemned as stated above to fines of $300 to $375, with the costs of the suit, which amounted to about $25,000. The expert testimony in the case is reported in full in the *Münchener med. Wochenschrift*, Dec. 20, 1904.

LONDON LETTER.

Plague Inoculation in India.

The rapid spread of plague in the Punjab during the cold weather of 1901-2 led the government of India to make provision for the inoculation of no fewer than 7,000,000 persons during the following winter by the combined efforts of all the available medical establishments and of 37 doctors especially engaged in England. But when the scheme had been in operation only four or five weeks, it was brought to a summary close by a deplorable catastrophe, which has been previously referred to in The Journal. On Nov. 6, 1902, nineteen persons who had been inoculated at a certain village from a single bottle of the Haffkine serum were found to be suffering from tetanus and all subsequently died. The chief justice of Bombay and two medical officers of distinction were appointed as a commission of inquiry. After prolonged delay, due to the submission of the report of the commission for examination and to further experiment at the Lister Institute in London, an official report has been issued. It states that in September, 1902, the standard method of manufacturing the Haffkine serum was changed by the director of the Plague Institute on his own authority, with the object of expediting the process and thus meeting the enormous demand made by the Punjab government. The change involved the omission of a small proportion of the carbolic acid, which had up till then been added to the original fluid as a precaution against contamination. The commission found that the tetanus bacillus was introduced before the bottle was opened, and thought that this occurred owing either to insufficient sterilization or to the process of filling the bottle from a larger flask having been performed with defective precautions. They expressed the opinion that carbolic acid was a valuable agent in restraining the growth of the tetanus bacillus when added to the plague serum and that its omission was a grave mistake. Experiments undertaken in India by two independent investigators confirm this view. The conclusions of the Lister Institute also generally confirm those of the commission. With a view to re-establish public confidence in the safety of the serum, arrangements have been made for a series of public demonstrations of the process of manufacture by the director of the Plague Research Laboratory in connection with the Health Exhibition organized by the Bombay Sanitary Association.

Physical Degeneration.

The question of national physical degeneration has been much discussed recently, both in the lay and in the medical press. Alarmist views stating that the national physique is undergoing serious degeneration have been put forward, but have not been proved. They seem to have been largely due to the journalism of the day, which finds sensationalism more profitable than truth. However, it is perfectly true that the physique of a large portion of the inhabitants of towns is far from satisfactory. At a meeting of the Society of Medical Officers of Health, Sir Lauder Brunton read an important paper on "Physical Degeneration." He pointed out that 34.6 per cent. of recruits for the army are rejected on inspection, and 3 per cent. more are either rejected within three months or discharged as invalids before completing two years' service. He advocated the proposal that school children should be periodically inspected. He discussed the part which health officers might play in the work, suggesting that they should see that proper accommodation is provided for play in good weather and for exercise in bad weather; that they should advise on the problems of feeding school children, and should see that the schools become great object lessons in ventilation and dietetics. He advocated school kitchens, and anticipated that by the agency of lady visitors to the homes the health officers could work to great advantage and could also convey instruction as to the feeding of infants. Instead of the municipalization of milk depots, he recommended that the large dairy companies should be obliged, under a heavy penalty, to supply milk which would conform with the requirements laid down by the municipalities. The country must be made more attractive in order to draw people from crowded towns. Local authorities should exercise their powers to treat overcrowded houses as nuisances.

The Jews and Infantile Mortality.

In an address on the sanitary condition of Manchester, Dr. Rhodes pointed out that though the general death rate had fallen considerably, the infantile mortality was almost as high as it was fifty years ago. It is comparatively low in the Jews' quarter, where the mothers stay at home and look after their children. The publication of this address was followed by an interesting letter to the *Manchester Guardian*, by "A Jewess," who stated that it had been shown by several investigations that Jewish children are superior to gentile in stamina and physique. This she attributed primarily to the fact that Jewish mothers do not work in factories, for it is considered a disgrace for a man to let "the mother of his children go to the factory, working above her strength and depriving her children, before their birth and after it, of the care which is their right." In cleanliness she did not consider that the lower class Jews, many of whom came from the ghettos of Russia and Poland, had any superiority, but they had the advantage of freedom from alcoholism.

Plague and Other Infectious Diseases in Rats.

The annual report of the medical officer of the local government board contains an important paper by Dr. Klein on this subject. He made a carefully conceived series of experiments to ascertain the channels by which plague is conveyed from rat to rat. His experiments do not support the generally accepted view that the disease is largely conveyed by fleas. He could not find, as Dr. Tidswell did, that an emulsion of fleas taken from a rat dead of plague is capable of conveying the disease to other rats According to Dr. Klein, fleas may occasionally convey plague from rat to rat, but this is not the common method of conveyance. On numerous occasions he kept rats in the same cage for some time in order that their initial fights might cease, and then inoculated one with plague from which it died, but none of the others succumbed, and their susceptibility was subsequently proved by inoculation. Dr. Klein thinks that one of the most common causes of infection from rat to rat is by means of the wounds and abrasions which are to be found on nearly all rats in the wild state. Such abrasions may easily become inoculated by articles soiled by the excreta of rats ill with plague. He thinks that rats may also be inoculated owing to their fighting propensities and to the fact that when ill with plague they are extremely irritable. In the case of a rat afflicted with pneumonic plague, the oral mucus would thus be a ready means of infection. An interesting part of the report is that which relates to disease other than plague in rats Dr. Klein refers to the disease caused among rats by the Danysz bacillus, by means of which it was sought to destroy the rats in the Paris sewers This bacillus is easily distinguished from that of plague In the case of the SS George Royle, on board of which many dead rats were found while it was being unloaded at Bristol, the case was complicated by the fact that the vessel came from Smyrna, which was infected with plague. Much alarm was naturally caused, but it was eventually proved by Dr. Klein that the bacillus which presumably had caused the death of the rats was not that of plague, but a bacillus which he termed *Bacillus bristolense*. The report is valuable as indicating caution in concluding that a fatal disease among rats on board ship is necessarily due to plague.

TESTS FOR ACETONE AND INDICAN

Mt Vernon, N. Y, Jan 17, 1905

To the Editor:—In your issue of January 7, page 53, reviewing Croftan's clinical urinology, you refer to Penzoldt's test for acetone and Strauss' method for quantitative indican determination Will you kindly publish those methods and give reference to original papers? F

Answer—The indigo test of Penzoldt depends on the transformation of orthonitrobenzaldehyd into indigo blue A few crystals of orthonitrobenzaldehyd are dissolved in hot water and, after cooling, a little of the fluid to be tested and some sodium hydrate solution are added If acetone be present the fluid turns yellow, then green, and then blue (indigo formation) If desired, the indigo can be shaken out with chloroform and further tests for its identity made The test can be applied directly to the urine, and will yield a positive reaction if acetone be present in abundance, but for the detection of small amounts of acetone it is necessary to distill off 30 to 40 c c from 250 c c of urine, using a cooler The most of the acetone passes over in the first 10 to 20 c c of the distillate, and the test is applied to the distillate Penzoldt's test is very reliable and free from objection Many prefer it to Legal's test Penzoldt's article will be found in the *Deutsches Archiv f Klin Med*, vol xxxiv (1883), p 132 Recent studies by Ellram and also by von Melckebecke confirm the reliability of the test Strauss' method for the determination of indican, in a rough way, quantitatively, for clinical purposes, is as follows Twenty c c of urine are mixed with 5 c c of a 20 per cent solution of acetate of lead Ten c c of the filtrate (equal to 8 c c urine), are placed in a separating funnel, which is closed below by a glass stopcock and above with a glass stopper; it is graduated to 5, 10, 15, 20 and 25 c c To the 10 c c of the filtrate are added 10 c c of Obermayer's reagent (concentrated hydrochloric acid containing 2 grams of perchlorid of iron per liter) and 5 c c chloroform; the tube is shaken gently several times, allowed to stand for some time and shaken again The chloroform solution is then drawn off, more chloroform placed in the separating funnel, and the process repeated until the chloroform extracts no more color After this 2 c c. of the combined chloroform extracts are placed in a test tube of the same size and form as the test tube containing a control solution of indigotin in chloroform (1 mgr. in 1,000 c cm). The colored chloroform solution is diluted with pure chloroform until the color is the same as that of the control solution. The quantity of indican present is easily calculated If x is the amount of chloroform in cubic centimeters used for extraction, and y the amount used for dilution, then $\frac{1}{2}xy$ would give the chloroform value from which the amount of indigo can be calculated, it being remembered that the test solution contains 0 001 gm of chemically pure indigotin in 1,000 ccm and that 8 ccm of urine was used for the reaction. The control test tube of the standard solution should be kept in a dark cupboard Strauss has published his method in the *Deutsche med Wochenschrift*, vol. xxix (1902), p 299 A somewhat similar colorimetric method has been introduced by J. Bouma (*Deutsche med. Wochenschrift*, vol xxviii, 1902, p 705). Bouma uses a so called indicanurometer which consists of eleven test tubes of the same size and thickness arranged in a row Six of these contain a solution of indigo red (of urinary origin) in chloroform, the strength varying so as to correspond to 5, 10, 15, 20, 30 and 40 mg of indigo per liter of urine The tubes are hermetically sealed and serve as control solutions They must be kept in the dark To make Bouma's test, 10 ccm. of urine are precipitated with 2 ccm of lead acetate solution One places 5 5 ccm of the filtrate (=5 ccm urine) in a test tube and adds 10 ccm of isatin hydrochloric acid solution (20 mg. purest isatin [Merck] dissolved in 1 liter chemically pure, iron-free, concentrated hydrochloric acid). The tube is heated to boiling for some seconds, then cooled and the contents extracted by shaking with 5 ccm chloroform This chloroform extract is compared with the six control solutions and the quantity thus immediately determined It must be emphasized that these tests give only approximately accurate results, though they are perhaps sufficient for clinical work More accurate methods, but much more difficult of application, are those of Wang (*Zeitschr f physiol Chemie*, vol xxv, 1898, p 406), and of J. Bouma (*Zeitschr. f physiol Chemie*, vol xxxii, 1901, p 82).

ANTIQUATED TEACHING IN MEDICAL COLLEGES

————, ——, Jan 18, 1905

To the Editor:—Will you kindly suggest to me some way out of the following difficulty satisfactory both to the students and to the dignity of the professor involved? A colleague of mine is the professor of two branches in the medical curriculum of a certain college He teaches one branch to second year men, the other to fourth year men The requirements of admission to the school have increased in the last few years to such a degree that many of the men who take their second year under him are better prepared in this particular subject than he is Mutterings have occurred before but I accidentally learned that the men were agitating a petition to have this particular man teach them the subject as it is to day and not as it was ten years ago The professor involved is the most influential member of this unendowed faculty and personally a warm hearted, genial gentleman, as well as a good friend of mine, so I stopped the petition for these reasons and the fear that the ringleaders (the best qualified men in their class) would be expelled Now, two or more of us have recognized the antiquated teaching of this important subject What can we do? If you desire to publish this, kindly withhold the city and my name and try to offer me a solution for the trouble

A. B. C

Answer—The case referred to is perhaps by no means an isolated instance Although we withhold the name of the city, as our correspondent suggests, we think it wise to state that the college referred to is not located in Russia, in spite of the fear expressed lest the "ringleaders" be "expelled" for asking for a square deal Could not the petition be framed so as not to speak disrespectfully of this evidently heavy stockholder? The matter, of course, ought never to have gone so far as to make it necessary for the students to risk being plucked by preparing this petition The only right course to pursue now is for those who recognize the situation to explain it to the member referred to fairly and squarely, but in a gentlemanly and tactful manner, and afterward to bring the matter before the faculty If this does not speedily secure the desired result, those who stand for honesty and for up to date medical instruction should not continue to be associated with the institution In terminating their connection, they should state publicly the exact reason for their resignation If a few men were to do this it would make a vast difference in the medical teaching of many schools in this country For a physician to be connected with a school which gives out of date, insufficient and hence harmful instruction of this sort is to endorse that deficiency and is a discredit to the man

SPELLING AMONG IRREGULARS

————, ——, Dec 26, 1904

To the Editor:—The enclosed is an exact copy of an affidavit of "Dr." — — ————, which the county attorney gave me several years ago and which I know to be genuine This old doctor lives in the hills of ——— county, ———, and has been practicing medicine for over forty years. He never entered a medical college in his life, nor made a dissection. Although a very ignorant man, living in a little log house in a remote part of the country twenty miles from a railroad, he has patients from every state in the Union, and, like a great many quacks, performs some very miraculous cures (?). He is permitted to practice medicine in this state under the act of ——, having practiced medicine fifteen years prior to the above date. He became a member of the pharmaceutical association by sending that body $1. He is also on the staff of the St. Luke's Hospital, Niles, Mich., for the certificate of which he paid $10.

C. Y.

> Thys iz too sertafi tht i Hav Maid A fisikal Exam Of Willum D—— & find his Fisikal Helth vry week. he has skroflon ditis & asmos ditis his harte Is week & his blud Dont hav Kurrent Flo thro arters, i find he's Rupert in Grine and, and Abdom. his mind Wavers and he has Hall Lucy-nations and is Esy skert and he dont no howe too wurk kase His minde iz incent and i konsider hym A Fit subjick fer Silum
>
> Dr. — — ———, md. p.m, m.p.s.

Our correspondent explains that "skroflon ditis" means scrofulous diathesis; "asmos ditis," asthmatic diathesis; "incent," insane; "arters," arteries; "Rupert," ruptured; "p.m," postmaster; "m.p.s.," member of pharmaceutical association. In this connection we will also quote a letter received by Dr. W. F. Morrow, secretary of the Missouri State Board of Health.

> Dear Sir, I rite you these lines few lines to find out the requirements to Practis *Medison in the state of* Missouri i am a man that Thurruly understand dease. Lokate Dease By the appearance of the Tongue and other sins and the Different stages in the same manner also the Different Treatments in the Different stages. Thurruly understand all Kinds of Feavers, Inflemarity Deases in their Different forms, the Different Treatment as the Forms calls for also variolus Different affections of the Kidneys and their Different Treatments, also Different forms of Rumatic affections in their Different Tipes. *Also Heart affections of* various Forms as They appere and their Treatment *also Dease of the Nearves, Fits of all carecters* arising from the Brain Nerves and Mussels and their Different Treatments, also the many Different affections of the Throat such as Laringitas Diptheria and all other affections, Lung Troubles and all other Deases to numerous to mention. i received My Knowledge of Dease and the Practis of Medison under My Frends they were doctors. They Practese with the Benefit of Both Schools and that is what i have and thirty years instruction from a practice of sixty years. Please rite me.

IMMUNITY AND PHAGOCYTOSIS.

MILWAUKEE, WIS., Jan. 12, 1905.

To the Editor:—Please tell me where I can get some recent papers, in the English language, on "phagocytosis." I have Metchnikoff's latest article on that work in German, but am unable to translate it. Is there an English translation? Any recent article on "Immunity and Susceptibility" will probably answer my purpose as well if the theory of phagocytosis is well discussed.

DR. J. E. BINGHAM.

ANSWER.—Consult the special article on "Immunity," which begins in this issue of THE JOURNAL, page 294. The work of Metchnikoff on "Immunity in the Infectious Diseases," 1901, is the most authoritative and comprehensive treatise on the subject of phagocytosis. S. G. Binnie recently translated this work into English (The Macmillan Company, New York, 1904). Advances of the greatest importance in the study of phagocytosis have been made recently in England by Wright and Douglas (Proc. of the Royal Soc., London, 1903, vol. 72, p. 357; *Ibid.*, 1904, vol. 73, p. 128; *Lancet*, London, 1904, vol. 2, p. 1138; *Brit. Med. Jour.*, 1902, vol. 1, p. 73). The work of Wright and Douglas has been extended in important particulars in this country by Hektoen and Ruediger (*Jour. of Infectious Diseases*, 1905, vol. 2, No. 1). See also: Wesbrook, "Phagocytosis," *Northwest Lancet*, 1903, vol. 23, pp. 182-184 (Minneapolis). Our correspondent can certainly get the article he refers to translated in Milwaukee; if not we shall be glad to have it done for him.

ESTIMATED EXPENSES TO PORTLAND.

CINCINNATI, Jan. 17, 1905.

To the Editor:—Will you kindly let me know what the probable expense of the trip to Portland for the next session of the American Medical Association will be, as I would like to have this and make my plans accordingly?

H. W. B.

ANSWER.—The expenses of the trip will vary with the individual and his habits. From Cincinnati the railroad fare for the round trip will be about $60; sleeping car, double berth, both ways, $28; meals ($1 each), both ways, $20; hotel expenses at Portland, five days at $5, $25, or a total of $133. Of course, if one desires to be economical, these expenses can be reduced. By "doubling up," $14 can be deducted from the sleeping car expenses, or even more reduction is possible by *taking a tourist sleeper.* The dining car service is usually *a la carte*, and the average meal can be reduced below $1. Hotel accommodations can be obtained at much less than $5. These figures are based on a trip direct to Portland and return, without stopping on the way. We doubt if any will make such a long trip without taking advantage of some side excursion, and the expenses of this, of course, each individual must estimate for himself.

THE X-RAY IN PSORIASIS.

CAMBRIA, WIS., Jan. 13, 1905.

To the Editor:—1. What benefit, if any, is the *x*-ray in the treatment of psoriasis? 2. What number of exposures should be given in an average case of long standing before a noticeable improvement can be hoped for? 3. Are there any known cases recorded in which cures have been effected by the use of the *x*-ray?

C. E. S.

ANSWER.—1. Psoriasis can be cleaned up with the *x*-ray; the treatment has been given a thorough trial by dermatologists, with very satisfactory results. 2. The second question can not be answered in the form in which it is propounded. The number of exposures required depends entirely on the quantity of *x*-rays used in the exposure. It is not necessary usually to carry the exposures to the point of producing any reaction in order to get rid of a patch of psoriasis. 3. Numerous references to recorded cases will be found in the text-books on *x*-ray work, under psoriasis; for example, Pusey & Caldwell, and Williams.

BOOKS ON DIAGNOSIS BY THE MICROSCOPE.

LA AURORA., PUEB., MEX., Jan. 15, 1905.

To the Editor:—What is the best book on laboratory diagnosis, including technic of staining, preparation of stains and use of the microscope in making such diagnoses?

B. W. GREEN, M.D.

ANSWER.—Simon's "Clinical Diagnosis" (Lea Bros.); Lee's "Vade Mecum" (Blakiston); Oertel's "Medical Microscopy" (Blakiston); Mallory and Wright's "Pathologic Technique" (Saunders); Ewing's "Clinical Pathology of the Blood" (Lea Bros.). These can be ordered from any bookseller.

Marriages.

WILLIAM EARL HAMLIN, M.D., to Miss Fay Voohers, both of Pocahontas, Ark.

ANDREW J. WALLS, M.D., to Miss Ida Smith, both of Lonoke, Ark., January 4.

JOSEPH WEINBERG, M.D., to Miss Helen G. Kelly, both of Brooklyn, January 2.

CLARENCE E. APPLE, M.D., to Miss Emma P. Crowe, both of Philadelphia, January 8.

CHARLES F. DARNALL, M.D., to Miss Ona Parkhill, both of Llano, Texas, January 4.

JOSEPH DRIES, M.D., to Miss Marie Altmeier, both of Milwaukee, Wis., January 11.

J. HARRY CRAWFORD, M.D., to Miss Mary E. Madden, both of Castlewood, S. D., January 1.

JOHN H. MARTIN, M. D., to Miss Marie Glidden, both of Centerville, S. D., at Parker, S. D.

C. C. HATFIELD, M.D., Kingston, Ohio, to Miss Maud M. Grim of Columbus, December 28.

WILLIAM A. STARNES, M.D., to Miss Callie Barrow Torbett, both of Atlanta, Ga., January 11.

GEORGE S. EDMONSON, M.D., Clinton, Ill., to Miss Della B. Jones of Thawville, Ill., January 4.

W. W. LUCAS, M.D., New Washington, Ohio, to Miss Goldie Staley of Sidney, Ohio, December 25.

HALBERT F. NEAL, M.D., Meridian, Idaho, to Miss Grace Andrews of Peru, Neb., December 28.

EDWARD DANFORTH, M.D., New York City, to Miss Helen Mattice of Gilboa, N. Y., January 18.

OLIVER S. REILEY, M.D., Red Oak, Iowa, to Mrs. Estelle Whipple of Belvidere, Ill., January 17.

READDING LLOYD WILLIAMS, M.D., to Miss Eleanor Magdalen Henke, at Las Vegas, N. M., January 10.

ISAAC MARION BURNSIDE, M.D., to Miss Jessie May McDonald, both of Highmore, S. D., January 10.

SIDNEY J. HATFIELD, M.D., Indianapolis, to Miss Calhoun Peckinpaugh of Alton, Ind., December 28.

Prather B. Curlin, M.D., Hickman, Ky., to Miss Ruth Seates of Union City, Tenn., January 13.

William Russell Jones, M.D., Richmond, Va., to Miss Jane Taylor Fisher of Norfolk, Va., January 6.

Andrew R. G. Smith, M.D., North Whitefield, Maine, to Mrs. Maude Allen of Jefferson, Maine, December 31.

James Henry Ferrell, M.D., Woodlawn, Ala., to Miss Marion Lucile Edwards of Sylacauga, Ala., January 25.

Aural Alva Sandy, M.D., Washington, Iowa, to Miss Blanche May Foshier of Harvey, Iowa, January 18.

Winfred Morgan Hartshorn, M.D., New Haven, Conn., to Miss Edith May Lieb of New York City, January 11.

Augustus W. Thompson, M. D., Mineral Wells, Texas, to Miss Estelle Johnson of Jackson, Miss., January 11.

Rutherford B. Irones, M.D., San Francisco, to Miss Georgia E. Dow of San Diego, Cal., in Los Angeles, January 12.

Benjamin Austin Cheney, M.D., New Haven, Conn., to Miss Lillian Clark Farrel of Ansonia, Conn., January 11.

Albert Ralston Matheny, M.D., Pittsburg, Pa., to Miss Florence Belt Kitzmiller of Hawkins Station, Pa., January 24.

Charles A. Hauber, M.D., Walla Walla, Wash., to Miss Elletta Lydia Wiltfi of San Jose, Cal., at San Francisco, December 31.

Percy Fitzgerald McMurdo, M.D., acting assistant surgeon United States Navy, Charlotteville, Va., to Miss Genevieve Le Duc of Philadelphia, January 11.

Deaths.

Thos. H. Manley, M.D. New York University, New York City, 1875, member of the Mississippi Valley Medical Association; New York Academy of Medicine, New York County Medical Society; professor of surgery and surgical pathology New York School of Clinical Medicine; visiting surgeon to Harlem and Metropolitan Hospitals, died from pneumonia at his home in New York City, January 13, aged 54.

Albert G. Carr, M.D. Bellevue Hospital Medical College, New York City, 1870, formerly surgeon of the North Carolina State Troops; first vice-president and treasurer for eight years of the Medical Society of the State of North Carolina; president of the Durham County Medical Society, committed suicide while despondent, by shooting himself at his home in Durham, January 13, aged 54.

Josiah Peltz, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1867, a member of the American Medical Association, Medical Society of the State of Pennsylvania and Philadelphia County Medical Society, died at his home in Philadelphia from valvular heart disease following a severe attack of influenza, January 13, aged 62.

Charles H. Norred, M.D. St. Louis College of Physicians and Surgeons, 1865; Jefferson Medical College, Philadelphia, 1886; surgeon of the Seventh Illinois Volunteer Cavalry in the Civil War; special quarantine officer of Minneapolis during the smallpox epidemic of 1900, died at the Landour Hotel, Minneapolis, January 11, a few days after an operation.

Emmet Perdue, M.D. Marion-Sims College of Medicine, St. Louis, 1896, surgeon to the North American Coffee Company and Carbon Lumber Company; deputy health officer of Carbon County, Wyo., was shot through the back of the head and killed while in bed at his father-in-law's house near Richmond, Mo., January 18.

Peter B. M. Miller, M.D. Royal College of Surgeons, Edinburgh, Scotland, 1858, surgeon in the British army in India for ten years, a practitioner in Australia and New Zealand; since 1882 a resident of Seattle, Wash., died at his home in that city, December 2, from cancer of the mouth, after an illness of four years, aged 69.

Duncan Reid, M.D. Rush Medical College, Chicago 1878, a member of the American Medical Association; for two years a self-supported medical missionary on the west coast of Africa, died at his home in New Hampton, Iowa, January 11, from valvular heart disease—aortic stenosis—aged 58.

Louis E. Foudruat, M.D. Faculté de Médecine, Montpellier, France, 1864, surgeon in the army of Maximilian in Mexico; coroner and parish physician for twenty-four years, and president of the local board of health for ten years, died at his home in St. Bernard, La., after a long illness, aged 63.

Arthur O'Leary, M.D. Jefferson Medical College, Philadelphia, 1866, while depressed from financial difficulties and suffering from injuries received in a street-car accident, ended his life, January 18, by shooting himself through the heart at his home in Cleveland, Ohio, aged 75.

Henry R. McComb, M.D. Rush Medical College, Chicago, 1881, for two years mayor of Shawano, Wis., and for four years county judge of Shawano County, died at his home in Shawano, January 10, from nephritis, after an illness of several years, aged 50.

William J. Gautier, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1850, for half a century a practitioner of Tuskogee, Ala., died at his home in that city, January 13, from heart disease, after an illness of one week, aged 79.

William Aills, M.D. Tulane University of Louisiana, Medical Department, 1853, surgeon of the Sixth Mississippi Infantry, C. S. A., and brigade surgeon in the Civil War, died at his home in Steen's Creek, Rankin County, Miss., January 14, aged 80.

Odelia Blinn, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1868, formerly prominent in professional and social circles in Chicago, died at the Cook County Infirmary, Dunning, January 20, after an illness of six years, aged 60.

George W. Harrison, M.D. Rush Medical College, Chicago, 1881, of Ashland, Wis., once a member of the Wisconsin State Board of Medical Examiners; second mayor of Ashland, died January 12 at Grand Rapids, Mich., from heart disease, aged 55.

Leonard J. Gordon, M.D. Bellevue Hospital Medical College, New York City, 1875, director of the Jersey City Public Library, died at his home in Jersey City from heart disease, January 17, after an illness of three months, aged 60.

Stephen M. Switzer, M.D. University of Vermont Medical Department, Burlington, 1880, died at his home in Bradford, N. Y., January 7, from paralysis following diphtheria, after an illness of several weeks, aged 56.

Daniel O. Polin, M.D. Medical Department of the St. Louis University, 1851, president of the Washington County (Ky.) Medical Society, died at his home in Springfield, January 14, from heart disease, aged 75.

John R. Howes, M.D. Medical College of Ohio, Cincinnati, 1879, of Las Comas, N. Mex., representative in the Minnesota Legislature in 1884 and 1885, died suddenly in El Paso, Tex., January 10, aged 56.

John McJunkins, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1879, died at his home in Tuccoa, Ga., January 10, from nephritis, after an illness of two months.

Franklin Byington, M.D. University of Georgetown, Washington, D. C., 1858, surgeon in the Confederate service during the Civil War, died at his home in Charlestown, W. Va., January 14, aged 66.

James Leslie Harding, M.D. Starling Medical College, Columbus, Ohio, 1883, died at his home in Blairsville, Pa., January 10, from cerebral hemorrhage, after an illness of several days, aged 45.

Edward D. Bernreuter, M.D. Missouri Medical College, St. Louis, 1880, a member of the American Medical Association, died at his home in Mount Olive, Ill., December 9, aged 46.

Charles E. Oatis, M.D. Transylvania University Medical Department, Lexington, Ky., 1846, died at his home in Hazlehurst, Miss., January 6, from cerebral hemorrhage, aged 81.

James D. McKnight, M.D. Memphis (Tenn.) Hospital Medical College, 1882, sheriff of St. Francis County, Ark., died suddenly at his home in Forrest City, January 8, aged 62.

J. P. Lowery, M.D. Vanderbilt University Medical Department, Nashville, 1879, died recently at his home in Renner, Texas, and was buried at Corsicana, Texas, January 15.

Michael R. Kelly, M.D. Rush Medical College, Chicago, afterward prominent as an educator, died at his home near Morrison, Ill., recently, and was buried January 7; aged 84.

Gustavus Nelson, M.D. Louisville Medical College, 1893, died at his home in Trufant, Mich., January 12, from hemorrhage of the stomach, after an illness of three days, aged 50.

John S. Smalley, M.D. Ohio Medical University, Columbus, 1893, died at his home in Newark, N. J., January 8, from nephritis, after an illness of three months, aged 49.

S. R. Hubbard, M.D. University of Nashville Medical Department, 1862, died at the home of his son in St. Augustine, Fla., January 1, after a long illness, aged 70.

James H. Cossaart, M.D. New York, 1870, of Otego, N. Y., died at a hospital in New York City, January 2, four days after an operation for cholelithiasis, aged 58.

John H. Donaldson, M.D. Starling Medical College, Columbus, Ohio, 1881, died at his home in Gore, Ohio, from cerebral hemorrhage, after an illness of a year, aged 56.

Robert B. Dupree, M.D. Bellevue Hospital Medical College, New York City, 1874, died at his home in Marlin, Texas, January 11, after a prolonged illness, aged 54.

William H. Ensminger, M.D. Jefferson Medical College, Philadelphia, 1871, died suddenly at his home in Chicago, January 17, from cerebral hemorrhage, aged 61.

Seth R. Beckwith, M.D. Ohio, 1853, of New York City, physician to the late President Garfield, died at Atlantic City, January 20, after an illness of a year, aged 72.

S. Cordelia Enos, M.D. Illinois, 1891, died at her home in Jerseyville, Ill., January 17, from injuries sustained in an explosion of gasoline the day before, aged 60.

Thomas M. Johns, M.D. Rush Medical College, Chicago, 1877, died at his home in Taylorsville, Ill., from liver disease, after a long illness, aged 58.

John B. Adams, M.D. Medical College of Alabama, Mobile, 1898, died at his home in Clanton, Ala., January 10, after amputation of both feet.

Robert P. Lake, M.D. University of Maryland School of Medicine, Baltimore, 1849, died at his home near Locust Dale, Va., recently, aged 83.

John A. Hamilton, M.D. Jefferson Medical College, Philadelphia, 1876, died at his home, Pollock, La., January 11, aged 70.

Thomas N. Livesay, M.D. Rush Medical College, Chicago, 1868, died at his home in Patoka, Ill., January 10, aged 68.

Ewing Peyton Biggs, M.D. Cincinnati, 1878, died at his home in Lutesville, Mo., January 4, from heart disease, aged 52.

Gustave Schmidt, M.D. University of Breslau, Germany, 1838, died at his home in Ingraham, Ill., December 1, aged 88.

Samuel G. Weagley, M.D. Years of Practice, Illinois, 1878, died at his home in Jacksonville, Ill., December 7, aged 78.

A. G. Wertman, M.D. Baltimore University School of Medicine, 1898, died at his home in Effort, Pa., January 18.

Jesse Chewning, M.D. St. Louis Medical College, 1863, died at his home in Canton, Ill., Sept. 21, 1904, aged 65.

George H. Winkelmann, M.D. Cincinnati College of Medicine and Surgery, died in Chicago, December 19, aged 52.

F. Virgil Westfall, M.D. Medical College of Ohio, Cincinnati, 1889, died at Dahlgren, Ill., Nov. 23, 1904, aged 49.

John Pearson Iliff, M.D. Pennsylvania, 1883, died at his home in Philadelphia, January 11, aged 54.

Jeremiah Phillips, M.D. Cincinnati, 1855, died at his home *in Olney, Ill., Oct. 16, 1904, aged 88.*

Miscellany.

The Cytology of General Paresis.—Fischer reports two cases of paresis, of which the diagnosis was unquestioned, which were examined as to the condition of their blood cells by lumbar puncture during life with strikingly different results. In one there was almost entire absence of lymphocytes, in the other marked lymphocytosis. The autopsy in both cases revealed typical paretic meningeal infiltration. The conclusion he draws, in the *Präger med. Woch.*, is that we can not determine by the cytologic findings whether or not the meninges are specially inflamed, but only how strongly and how far they are infiltrated and to some extent whether the process is slow or rapid. Of course, the quantitative determination of the cells of the cerebrospinal fluid is only an approximate one. Another point noted in his observations is that the cells found by lumbar puncture are either identical with or of the same type as those in the meninges, and probably originate in the meninges, and we must assume a downward flow from the brain carrying them into the lower spinal region. Infiltration of the spinal meninges is an accompaniment of this condition even though the spinal cord itself may apparently be intact.

Overpressure in School.—Commenting on the scarcity of cases of chorea in the summer and fall, and the abundance of such cases seen in the late winter and spring, Dr. La Fetra, in the *Archives of Pediatrics*, attributes this condition in great measure to overwork in school. During October or November it is often difficult, even in a large ambulatory service, to collect sufficient cases for a clinical lecture on the various phases of chorea. As the seasons proceed, the cases increase slowly in number until about March or April, when there is a sudden rise in the number of those affected. Pale, thin, ambitious children, the majority of them girls, then throng the nervous and pediatric clinics in all stages of the disease. Probably the most important exciting cause, at least in those cases that are not clearly rheumatic, is excessive stimulation of the cortical cells of the brain. This results in the gradual supervention of undernutrition and consequently in overexcitability of these cells. The nature of the stimulation varies. It may be the social excitement of children's parties, long waking hours, a bad fright, great grief, strenuous games, too many or too long school periods, home study at night, or the strain and anxiety of class recitations; or, it may be improper food or indigestion; at any rate, the result is much the same. The child's nervous system becomes debilitated, loses its power of inhibition, and manifests the overactivity of weakness. St. Vitus' dance is cited merely as one of the extreme types of this nervous exhaustion. In the treatment it is pointed out that careful attention to the number and character of the different subjects, the length of the lessons and the time of study is necessary. Change of study or the alternation of physical exercise, games or manual training with mental effort is desirable; but it must be remembered that change of work, or change from work to play is not rest, although the result may be added interest in the new occupation. Change of employment is not recreation; for all effort fatigues. Children that need especially to be watched during the school year are those of alcoholic, tuberculous or neurotic family history, those that are anemic, those that are growing rapidly, especially girls at the period of prepubertal acceleration in growth, from 11 to 13 years, and those that have recently suffered from whooping cough, measles and diphtheria. Only by the exercise of caution in their school work can such children be prevented from suffering the ill effects of overpressure. Persistent headaches, not due to eye defects, disturbed sleep, morning languor and loss of appetite, are warning symptoms; if they persist after modification of the school régime, the child should be withdrawn from school for three or four weeks, or until all signs of nervous exhaustion have disappeared. Disregard of these early symptoms risks the more serious results of overpressure, such as chorea, neurasthenia, hypochondriasis, hysteria, and even epilepsy and insanity in patients of neurotic heredity.

State Boards of Registration.

COMING EXAMINATIONS.

New Hampshire State Boards, University Club, Concord, February 1-2. Regent, Henry C. Morrison, Concord.

Board of Medical Registration for Vermont, Burlington, February 7, 8 and 9. W. Scott Nay, M.D., secretary, Underhill.

Nebraska State Board of Health, State House, Lincoln, February 8-9. George H. Brash, M.D., secretary, Beatrice.

Kansas State Board of Medical Registration and Examination, Topeka, February 14-15. Secretary, G. F. Johnston, M.D., Lakin.

California December Report.—Dr. C. L. Tisdale, secretary of the Board of Medical Examiners of the State of California, reports the written examination held at San Francisco Dec. 6, 1904. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number examined was 40, of whom 24 passed and 16 failed. The following colleges were represented:

PASSED.

College.	Year Grad	Per Cent.
Cooper Medical College	(1904) 78 8, 82.1, 82.8, 84,	81 8
College of P. and S., Chicago	(1895) 86 1, (1902) 75, (1904)	76 9
	(1903) 75.7,	87 3
University of Michigan	(1901)	87.6
Rush Medical College	(1902)	83 3
Howard Medical College	(1902)	78 1
Jefferson Medical College	(1904)	77.6
McGill University, Canada		

University of Missouri	(1904)	75
Hahnemann Med. Coll., San Francisco, (1903) 75.7	(1904)	82.1, 82.6
Northwestern University	(1904)	82.2
University of California	(1904)	75
College of Med. and Surg., Minnesota	(1900)	85
Gross Medical College	(1902)	87.7
Starling Medical College	(1898)	82.1
Chicago Homeo. Med. Coll	(1888)	80.4
FAILED.		
Cooper Medical College	(1903)	65
University of Michigan	(1890)	62.3, 67
University of Berlin, Germany	(1899)	64.1
Rush Medical College	(1882)	69.3
Jefferson Medical College (1902) 68.1,	(1893)	36.4
Tufts Medical College	(1902)	59.2
Marion Sims-Beaumont Med. Coll	(1903)	67.7
Medical College of South Carolina	(1897)	70.4
Bellevue Hospital Med. Coll (1889) 69.7,	(1877)	66.4
University of Virginia	(1891)	62.6
University of Louisville	(1890)	68.5
College of P. and S, Chicago	(1901)	71.6
College of P. and S., San Francisco	(1904)	70.6

Oklahoma December Report.—Dr. E. E. Cowdrick, secretary of the Territorial Medical Examining Board of Oklahoma, reports the examination held at Guthrie, Dec. 2-8, 1904. The number of subjects examined in was 9; total number of questions asked, 85. No percentages are assigned by this board, but each candidate is required to attain a grade of 66.6 or over in each branch. The total number examined was 19, of whom 5 passed and 14 failed. The following colleges were represented:

PASSED.

University Medical College, Kansas City, Mo. (1904), had 1 representative; Northwestern University (1892), 1; Hahnemann Medical College, Chicago (1891), 1; Illinois Medical College (1904), 1, and Medical Department Drake University (1897), 1.

FAILED.

The following colleges had each one representative: American Medical Missionary College, Chicago (1903); Kansas City Medical College (1897); Baltimore University (1904); Baltimore Medical College (1896): College of Physicians and Surgeons, Baltimore (1885): University of Vermont (1904); University of Medicine, Kansas City, Mo. (1884); American Medical College, St. Louis (1904); Hospital Medical College, Kansas (1893): University of Michigan (1872); Rush Medical College (1900); Hospital College of Medicine, Kentucky (1889), and Barnes Medical College (1901).

Nebraska November Report.—Dr. George H. Brash, Beatrice, secretary of the Nebraska State Board of Health, reports the written examination held at Lincoln, Nov. 9-10, 1904. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number examined was 8, all of whom passed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Kentucky School of Medicine	(1904)	81.1
Kentucky Univ. Med. Dept	(1904)	78.1
Barnes Medical College	(1901)	78.1
[illegible] y	(1904)	85.1
[illegible] Chicago	(1882)	80.8
[illegible] llege	(1898)	86
[illegible] e	(1902)	81.2
[illegible] ege	(1900)	*77.1

Maryland June, September and October Reports.—Dr. Joseph H. Garrison, secretary of the Board of Medical Examiners of Maryland, representing the Maryland State Homeopathic Medical Society, reports the examinations held at Baltimore, June 7-8, September 30, and Oct. 26, 1904. The number of subjects examined in was 9; total number of questions asked, 70; percentage required to pass, 75.

At the June examination the total number examined was 13, all of whom passed. The following colleges were represented:

Southern Homeopathic Med. Coll., (1904) 77.4, 78.7, 81, 82.7, 83.7, 86.4, 88.1, 88.5, 88.7, 88.8, 92.5, 93.1.
Hering Medical College, Chicago (1904) 93.7

The general average of all representatives of the Southern Homeopathic Medical College was 85.8.

The examinations held September 30 and October 26 were oral. Only two persons were examined, both of whom passed.

Hahnemann Med. Coll., Philadelphia (1904) 75, 75

Ohio December Report.—Dr. Frank J. Winders, secretary of the Ohio State Board of Medical Registration and Examination, reports the written examination held at Columbus, Dec. 13-15, 1904. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number examined was 42, of whom 40 passed and 2 failed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Columbian Univ., Washington, D. C.	(1904)	91

Association News.

The Portland Session.

Dr. Kenneth J. Mackenzie, Chairman of the Committee on Arrangements, writes concerning arrangements for the session of the American Medical Association in Portland:

Hotel Arrangements have been placed in the hands of a committee, at the head of which is Dr. William Jones, and consisting of the following: Drs. R. C. Coffey, W. H. Skeene, C. H. Wheeler, A. E. Mackey and Mr. H. C. Bowers (by courtesy).

Mr. H. C. Bowers, the manager of the Hotel Portland, has undertaken to provide accommodations for any number that will attend the session. Mr. Bowers has informed the committee that he can readily take care of 4,000 or 5,000 visitors, and those who contemplate coming are requested to communicate with him and to make contracts for their accommodations without any delay. In anticipation of the Lewis and Clark Fair, the success of which is now an assured fact, the hotel and room capacity of the city has been greatly increased by 7,000 rooms from last year.

The management of the Lewis and Clark Fair have made arrangements with Mrs. McCready, who managed the American Inn at the St. Louis Fair, to build, within the city limits and within convenient distance of the center of the city, a hotel with a capacity of over 500 rooms. It will be better built than any structure of the kind that was in use in St. Louis, and a great many of the rooms will be furnished with baths. A large number of moderate sized but high-class hotels are under construction.

Excursions are being arranged by the local committee to take place on the Columbia River, which will enable the visitors to witness the choicest scenery of the Pacific Coast, including the unrivaled mountain scenery of the Cascade Range. Plans are being considered for excursions to Alaska and to the Orient. These arrangements, of course, will depend on a sufficient number of visitors announcing their plans in advance, indicating their intentions of making these excursions.

The most admirable arrangements have been made for the Section sessions.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Jan. 21, 1905:

Turnbull, Wilfrid, asst.-surgeon, advanced to rank of captain, to date from Jan. 16, 1905.

Egbert, R. G., surgeon, left from detached duty at Fort D. A. Russell, Wyoming, on 15 days' leave of absence.

Sweazey, Verge E., asst.-surgeon, reported at U. S. Army General Hospital, Washington Barracks, D. C., for treatment, from leave of absence.

Smart, Charles, brigadier general, retired as colonel and asst.-surgeon general, and advanced to brigadier general on retired list.

Hess, John H., examining and supervising dental surgeon, left West Point, N. Y., January 16, for San Francisco, Cal., en route to Philippine service.

Sparrenberger, Frederick H., contract surgeon, returned January 16 to Fort Mott, N. J., from leave of absence.

Wythe, Stephen, contract surgeon, returned January 10 to San Francisco, Cal., from leave of absence.

Foulkes, Bruce, contract surgeon, granted an extension of one month to his leave of absence.

Reitz, Hugo C., dental surgeon, returned January 17 to duty at Fort Sheridan, Ill., from leave of absence.

Ware, William H., dental surgeon, ordered to visit in succession, to render professional service, Fort Wingate, N. M.; Fort Apache, Ariz.; Whipple Barracks, Ariz.; Fort Huachuca, Ariz., and Fort Grant, Ariz.

Truax, Jesse P., contract surgeon, left Fort Lawton, Wash., January 14 for his proper station, Fort Ward, Wash.

Long, Charles J., dental surgeon, ordered to proceed at the expiration of his present leave of absence to Fort Snelling, Minn., for duty.

Hussey, Samuel W., dental surgeon, relieved from duty in the Department of Dakota and ordered to San Francisco, Cal., to sail March 1 for Philippine service.

McAlister, John A., dental surgeon, relieved from duty in the Philippine Division March 10 and ordered to the United States for assignment.

Millikin, John D., dental surgeon, relieved from duty in the Philippine Division April 14 and ordered to the United States for assignment.

Casaday, George H., dental surgeon, relieved from duty in the Philippine Division April 21 and ordered to the United States for assignment.

Bernheim, Julien R., dental surgeon, relieved from duty in the Philippine Division May 27 and ordered to the United States for assignment.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Jan. 21, 1905:

Pleadwell, F. L., surgeon, detached from the Naval Dispensary, Washington, D. C., January 31, and ordered to duty at the Naval Hospital, Yokohama, Japan, sailing from San Francisco, Cal., February 14.

Plummer, R. W., P. A. surgeon, detached from the Naval Hospital, San Juan, P. R, and granted leave of absence until February 15.

Garton, W. M., P. A. surgeon, detached from the Naval Hospital, Yokohama, Japan, and ordered home.

Butler, C. S., P. A. surgeon, detached from the *Constellation*, Jannuary 18, and ordered to the Naval Hospital, San Juan, P. R., sailing from New York, N. Y., January 21.

Stuart, A., asst.-surgeon, detached from the Naval Hospital, San Juan, P. R., and ordered to Washingtoon, D. C., February 15 for examination for promotion, and thence home and to await orders.

Rodman, S. S., P. A. surgeon, ordered to the *Pensacola*.

Sellers, F. E., A. A. surgeon, detached from the *Gloucester* and ordered to the *Franklin*.

Alfred, A. R., surgeon, detached from the *Solace* and ordered to the Naval Station, Cavite, P. I.

McLarty, C., pharmacist, detached from the *Solace* and ordered to the Naval Hospital, Yokohama, Japan.

Public Health and Marine-Hospital Service.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine Hospital Service for the seven days ending Jan. 18, 1905:

Greene, J. B., P. A. surgeon, seven days' extension of leave of absence from January 7, granted by Bureau telegram of January 4, revoked.

Townsend, W., A. A. surgeon, Department letter of Nov. 22, 1904, amended to grant A. A. Surgeon Townsend leave of absence for twelve days, instead of 30 days, from Dec. 15, 1904.

BOARD CONVENED.

Board convened to meet at Washington, D. C., Jan. 19, 1905, for the physical examination of an applicant for the position of second assistant engineer, Revenue Cutter Service. Detail for the Board: Asst.-Surgeon General G. T. Vaughan, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended Jan. 20, 1905:

Alabama: Mobile, Dec. 19-Jan. 9, 3 cases from vessels in port.
Arkansas: Fort Smith, Dec. 10-17, 1 case.
Illinois: Chicago, Jan 8 14, 16 cases, 1 death; Danville, Jan. 8-14, 2 cases; Peoria, Dec. 1-31, 7 cases.
Kansas: Topeka, Jan. 8-14, 1 case.
Louisiana: New Orleans, Jan. 8 14, 7 cases.
Massachusetts: Everett, Jan. 8-14, 3 cases, 1 death; Hyde Park, Jan. 8-14, 1 case from Steamship *Cymric*.
Massachusetts: Everett, Jan. 8-14, 3 cases.
Dec. 1-31, 1 death; Jackson Co., Dec. 1-31, 1 death.
Minnesota: Clay Co., Jan. 3-9, 1 case; Morrison Co., Jan. 3-9, 1 case; Otter Tail Co., Jan. 3-9, 8 cases; Rice Co., Jan. 3-9, 2 cases; St. Louis Co., Jan. 3-9, 3 cases; Todd Co., Jan 3-9, 3 cases; Wadena Co., Jan. 3-9, 5 cases.
Missouri: St. Louis, Jan. 8-14, 17 cases.
New York: New York, Jan. 8-14, 2 cases.
Ohio: Toledo, Jan. 10 17, 2 cases.
Pennsylvania: Homestead, Jan. 9-15, 1 case.
South Carolina: Georgetown, Jan. 1-14, 10 cases.
Tennessee: Memphis, Jan. 8-14, 2 cases; Nashville, Jan. 8 14, 4 cases.
Wisconsin: Milwaukee, Jan. 8-14, 8 cases.

SMALLPOX—FOREIGN.

Brazil: Para, Dec. 1-14, 54 deaths; Rio de Janeiro, Dec. 12-18, 102 cases, 34 deaths.
France: Lyons, Dec. 18-24, 1 case; Paris, Dec. 28-31, 14 cases, 4 deaths.
Great Britain: Hull, Dec. 25-31, 1 case; London, Dec. 25-31, 5 cases; Manchester, Dec. 25-31, 2 cases; Newcastle on Tyne, Dec. 25-31, 3 cases; Nottingham, Dec. 25-31, 2 cases.
India: Bombay, Dec. 14-20, 25 deaths; Calcutta, Dec. 10-16, 1 death; Karachi, Dec. 12-18, 4 cases.
Italy: Catani, Dec. 23-31, 2 deaths; Palermo, Dec. 18 24, 14 cases, 5 deaths.
Panama: Colon, Jan. 1-8, 1 case.
Spain: Barcelona, Dec. 21-31, 11 deaths.

YELLOW FEVER.

Brazil: Para, Dec. 1-14, 18 deaths.
Mexico: Coatzacoalcos, Dec. 28-31, 2 cases; Juchitan, Jan. 1-7, 1 case.
Venezuela: *Maracaibo, Dec. 4-11, 1 case, 1 death.*

CHOLERA.

India: Bombay, Dec. 14-20, 1 death; Calcutta, Dec. 10 17, 108 deaths.
Russia: Dshewat, Dec. 8 14, 264 cases, 203 deaths; Hedjuff Dec. 8-14, 177 cases, 152 deaths.

PLAGUE.

Arabia: Crater, Dec. 17-24, 43 cases, 28 deaths; Hedjuff (Plague hospitals), Dec. 17-24, 5 cases, 7 deaths; Shaikh Othman, Dec. 17-24, 7 cases, 3 deaths.
Chile: Iquique, Dec. 4-17, 2 cases, 2 deaths; Santiago, Dec. 2, 1 case.
Egypt: Port Said, Dec. 10-17, 1 case 1 death; Suez, Dec 10-17, 1 case; Tukh District, Dec. 10-17, 1 case.
India: Bombay, Dec. 14-20, 102 deaths; Calcutta, Dec. 10 17, 15 deaths; Karachi, Dec. 12-18, 56 cases, 52 deaths.
Japan: Kobe, Dec. 16, 1 case.
Mauritius: Oct. 14-Nov. 3, 61 cases, 35 deaths.

Medical Organization.

Michigan.

ORGANIZATION IN MICHIGAN.—From a personal letter, dated January 23, received from Dr. Leartus Connor, chairman of the council of the Michigan State Medical Society, we quote the following: "Our Michigan council held its winter meeting last Friday. Work began at 8:30 a. m. and continued as rapidly as was possible till dark. We found ourselves ahead of last year in numbers and finances. Several knotty problems in different portions of our field had been solved pleasantly. Others are on the way to solution. The general tone of correspondence was higher than ever. But one complaining letter had been received during the past year. On the other hand, our advance has been small; several of our councilors had fainted with the work and wanted to give it up. Hence it was necessary to recharge them with enthusiasm, which was done, and they left determined to do better the coming year. Our limited time forbade a discussion of other than the necessary business and plan for the coming months. All this is better than I had anticipated. Five of the councilor districts have held district meetings, with profit to all in increasing enthusiasm and closer fellowship. Other district societies will be formed later."

Texas.

CENTRAL TEXAS (TWELFTH) DISTRICT MEDICAL ASSOCIATION.—The Central Texas Medical Association met at Waco, January 10 and 11 and reorganized on the standard plan as the Central Texas (Twelfth) District Medical Association, electing the following officers: President, Dr. Robert Alexander, Troy; vice-presidents, the presidents of the component county societies, and secretary-treasurer, Dr. John L. Burgess, Waco.

West Virginia.

GRANT, HARDY, HAMPSHIRE AND MINERAL MEDICAL SOCIETY.—At a meeting of 14 physicians of these counties, held at Keyser the first week of January, this society was organized with the following officers: Dr. Edgar H. Parsons, Piedmont, president; Drs. J. N. Judy, Petersburg, Grant Co., Robert W. Love, Moorefield, Hardy Co., George H. Thomas, Romney, Hampshire Co., and Lloyd L. Edgell, Keyser, vice-presidents; Dr. Percival Lantz, Alaska, secretary, and Dr. Monsell R. Bell, Keyser, treasurer.

Society Proceedings.

AMERICAN PUBLIC HEALTH ASSOCIATION.

Thirty-Second Annual Meeting, held at Havana, Cuba, Jan. 9-13, 1905.

The President, Dr. Carlos J. Finlay of Havana, in the Chair.

Addresses of welcome were delivered by Dr. Cancio, secretary of public instruction to President Palma, representing the Cuban government, and by Dr. Lincoln de Zayas, representing the medical profession of Havana.

President's Address.

After thanking the association for the great honor conferred on him in electing him president, Dr. Finlay referred to the first Havana yellow fever commission, which was established a quarter of a century ago and came from Washington. So well did this commission accomplish its object that he could readily trace back to its immediate influence the discoveries which led the way to ultimate success. He stated that the sanitary experience in Cuba during the last twelve months, both with regard to yellow fever and to smallpox, had been somewhat more eventful and at the same time more instructive than in the preceding two years. In the district of Havana, notwithstanding the admission of imported cases of yellow fever from foreign ports, not a single case, originating on the island, had been recorded. With the experimental proofs that they now possess that fomites *per se* were incapable of transmitting the disease, the inevitable conclusion must be that in the cases mentioned infected mosquitoes had been conveyed on floating bodies by the ebb-tide. The fight against tuberculosis must be maintained at all costs as the most important factor in mortuary statistics of large towns almost all over the world. The study of causes and prevention of infant mortality is one which affects Cuba not only with reference to infantile enteritis, but also with regard to tetanus neonatorum, the occurrence of which is coupled with unpardonable ignorance or neglect both on the part of parents and of the attendants at the birth of children. The control of milk supplies in large cities is closely connected with infantile mortality, for the methods best calculated to carry the former into effect should undoubtedly lessen the latter. Finally, the subject of sanitary agreement between adjoining nations has become of paramount importance since the recent advance made in our knowledge of the etiology of certain quarantinable diseases, of yellow fever in particular. Hence the advisability that European nations holding possessions in the American yellow fever zone be represented at the meetings of the association.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. F. F. Wesbrook, Minneapolis, Minn.; vice-presidents, Dr. Juan Guiteras, Havana, Cuba; Dr. F. Lopez, Mexico City, Mexico; Dr. Geo. MacDonald, Brandon, Manitoba; executive council: Drs. Marcus Haas, Memphis, Tenn.; C. V. Chapin, Providence, R. I., and Wm. C. Chapman, Toledo, Ohio; secretary, Dr. Chas. O. Probst, Columbus, Ohio (re-elected); treasurer, Dr. Frank W. Wright, New Haven, Conn. (re-elected). Boston was selected as the next place of meeting.

Purification of the St. Louis Water Supply By Coagulation and Sedimentation.

Dr. C. A. Snodgrass, St. Louis, said that from the year 1832, the time at which the first water works system of St. Louis was installed, until 1904, the water supply of St. Louis had been unsatisfactory, and that in a few months' time a complete transformation of the quality of the water had been secured by using ferrous sulphate and calcium hydroxid as a coagulant, followed by plain sedimentation. The present plant cost only $10,000. The plan of operation costs $4.50 less per million gallons than any other proposed plan. The exact and extensive chemical and bacteriologic data added to the physical properties proved conclusively that a water of a high degree of potability was being secured. The removal of suspended matter was shown to average 96.9 per cent., while the bacterial removal averaged 95 per cent. in many weekly analyses, showing an efficiency of 99 per cent. Mineral analysis showed that there was nothing left in the water that could be inimical to health. The death rate from typhoid during the last year has been materially lowered, but owing to the limited time of operation of the present system no deductions from this point of view were insisted on. Reports from engineers and manufacturers showed that the treatment given the St. Louis water supply was highly satisfactory to their interests. The author claimed that, with contemplated changes of a minor character, the expense of operation would be lowered and the efficiency increased.

Mr. F. S. Hollis, New Haven, Conn., described a practical test of the copper sulphate method for the removal of germs from water supplies.

Report on Purification and Preservation of Water Supplies.

Mr. George W. Fuller, New York, stated that the principle of the use of sulphate of copper in treating water supplies was not a new one, as it had been used for thousands of years. With reference to filtration, he said the number of cities in the United States with a population of 25,000 now using the filtration plan was about 8 per cent.; those which had filters under construction, 11 per cent.; those in which filters had been authorized, 20 per cent., and those in which filters were being considered as necessary, 31 per cent. Statistics and arguments were advanced in favor of filtration as a method of purifying water supplies of cities.

DISCUSSION.

Dr. Frank Warner, Columbus, Ohio, stated that more attention should be given to the better protection of the watershed. This feature was either neglected or overlooked in connection with modern purification plants. This was especially true of pollution near the purification works, and the water should be delivered to the purification plant in as pure condition as possible before purification.

Mr. H. W. Clark, Boston, said that since the introduction of filtration at Lawrence, Mass., the city had increased in population from 45,000 to 75,000, and the percentage of deaths from typhoid fever had been materially reduced.

Report of Committee on Disinfection and Disinfectants.

Prof. F. C. Robinson, Brunswick, Maine, reviewed the more important literature on the subject during the past year, especially in the foreign journals. As to experiments on disinfecting railway cars by formaldehyd, the results showed that it was practically impossible to completely sterilize all parts by the vapor of formalin, but still the experimenters think that it is the most practical thing to employ for that purpose. They recommend 1,000 c.c. of the liquid formalin to each car, but, of course, the foreign cars are much smaller than those in use in the United States. As to chemical methods for sterilizing drinking water, V. B. Nesfield recommends the use of tablets made from 1½ grains bleaching powder and ½ grain sodium bicarbonate. He claims that these will each sterilize a pint of water in five minutes, or better, ten. He removes the paste of chlorin by adding a tablet of sodium sulphite. He claims that by such use the most foul river water can be made free from disease germs and palatable. The report called attention to the danger of the spread of infectious diseases through library and school books. It was recommended that the danger should be met as far as possible by notices in libraries calling attention to the advisability of handling books with clean hands, of not touching the hands to the mouth after handling books until the hands are washed and, in addition, submitting books much used to the action of formaldehyd vapor once in a while. Remarkable results have followed the occasional use of weak solutions of formaldehyd on the floors of schoolhouses—solutions so weak that they gave no disagreeable odor. Infectious colds and other dust-borne diseases were much lessened among the scholars. The committee believes that the occasional use of such solutions on floors and surfaces in dwelling houses, as well as in public buildings, would do a great deal toward improving public health.

Sulphate of Copper with Lime to Destroy Mosquito Larvae.

Dr. A. H. Doty, New York, considered, first, the use of copper alone or in combination with lime for the destruction of mosquito larvæ; second, as a deodorant, and, third, as a disinfectant. He stated that in the destruction of mosquito larvæ and as a deodorant the use of copper in combination with lime is more effective than when used alone. This mixture destroys mosquito larvæ by rapidly removing from the water in which they were contained the organic matter or nourishment on which they depended for life, and this result is not due to a toxic effect produced by the copper or lime. Therefore, the range of usefulness of these agents, either alone or in combination, in the destruction of mosquito larvæ is limited. As to copper and lime as a deodorant, he believed it to be the most valuable and practical agent we possess for this purpose. Its action as a deodorant is rapid and permanent. It is practically harmless, cheap and easily made, and seems to comply with the requirements of a typical deodorant. Its range of usefulness is extensive, as it can be employed equally well for deodorizing solids or fluids. Little can be said regarding the germicidal value of copper at the present time.

The Disinfection of Schoolbooks.

Dr. Walter D. Green, Buffalo, N. Y., stated that an examination of the public school books early in 1902 revealed the fact that they were filthy, especially those used by the lower grades. These books were furnished gratuitously by the city, and consequently there existed a tendency to use them until they were literally in pieces—a period covering several years. It was thought that these filthy books, worn and handled by so many diminutive individuals, might be, and probably were, a source of contagion, and it was decided to disinfect them. The books were placed on their edges, with covers widely separated, on tables and shelves in tightly sealed rooms. Formaldehyd gas was liberated in the room, six ounces of a comparatively fresh commercial formalin being used for every 1,000 cubic feet of air space, the vaporization being induced by the use of wood alcohol being burnt in a receptacle containing the formalin. Bacteriologic examinations were made of the soiled leaves of books both before and after the disinfection, and it was found that about 85 per cent. of all organisms were killed. For the three years immediately preceding this schoolbook disinfection—that is, 1899, 1900 and 1901—the average number of cases of scarlet fever reported yearly to the health department by physicians in Buffalo was 875, while the average yearly deaths for the same time were 36. For the three years following such disinfection the average number of cases reported yearly was 528, and the number of deaths yearly for the same time was 18.

The Sources of Infection.

Dr. Charles V. Chapin, Providence, R. I., after pointing out various sources of infection, directed attention to isolation and disinfection. He said that it was perfectly plain, if we could isolate every case of a given contagious disease until all infection had disappeared, the disease would not merely decrease, but it would be exterminated. If we could only control one-half, one-quarter, or one-tenth of the foci of infection, it was equally clear that the disease would never be exterminated, and it was not even certain that it would diminish. The relation of probable success to the efforts made must decide the extent of those efforts.

Sanitary Conditions of Havana and Further Requirements for Their Improvement.

Dr. Erastus Wilson, Havana, said that the prevailing annual mortality in the city of Havana previous to American intervention—1898-1902—approximated 40 per 1,000. The general cleaning up of public places and rigid house-to-house inspection and abatement of insanitary domestic conditions, together with filling the puddle holes and irregularities in the macadamized streets, with the prohibition of the ejection of domestic wastes into the by-ways, obtained immediate and notable reduction in the mortality rate in the city. The continuation of these sanitary measures reduced the type of mortality and morbidity to about 50 per cent. of its former rate, besides beautifying the city and making it infinitely more attractive for residents who were interested in health and general culture. The author called attention to a further requirement of sanitary science, which was radical and indispensable, namely, a modern system of sewers of proper section, regularly graduated in size and declivity from their incipience to outfall, impermeable throughout and connected with the closets of every house by lead-jointed, cast-iron pipes, uniting them to the sewer outside the domicile.

The following resolution was adopted:

Resolved, That the association congratulates the civic authorities, the physicians and the people of Havana in general on the gratifying improvement made in its sanitary condition, and especially on their work in freeing their beautiful city from any danger from that once-dreaded scourge, yellow fever, by their persistent and skillful campaign against the yellow fever mosquito. We are especially gratified also that they do not propose to rest contented with what has been done, great as it is, but have already planned other sanitary improvements of great importance, including an efficient system of sewerage, which we wish them godspeed in carrying out at the earliest practicable moment.

Bacillus Tuberculosis in Man and Animals.

The report of this committee was read by Dr. V. C. Moore. He said that since the last meeting several important pieces of work had been reported. These were detailed in the report. The committee carefully compared the disease set up in the bovine animal by material of human origin, and so far it had found the one, both in its broad, general features and in its wider histologic details, to be identical with the other. It had so far failed to discover any character by which it could distinguish one from the other; and its records contained accounts of the postmortem examinations of bovine animals infected with tuberculous material of human origin which might be used as typical descriptions of ordinary bovine tuberculosis. At the laboratory of the State Live Stock Sanitary Board of Pennsylvania, a third instance of infection with the bovine bacillus has been found. The patient was a child not quite 2 years old, that had been nourished the greater part of its life on cow's milk bought from the most convenient store. It developed a large abdominal tumor, which proved on autopsy to be a tuberculous new growth, involving the mesenteric glands and intestine. The lungs were not involved. Cultures were obtained from this tumor, which had the cultural and microscopic characteristics of the bovine bacillus, and proved fatal to a calf weighing 211 pounds in thirty-five days. The committee did not yet feel able to say with what frequency bovine infection of man took place, but it was evidently not a rare occurrence. The committee considered that the evidence going to show that such infection did take place was absolutely conclusive, and that it not only justified, but made imperative, the passage of stringent laws by municipal and state authorities for the suppression of tuberculosis in cattle, and the prohibition of the sale of meat and milk from tuberculous animals.

Report of the Committee on Tuberculosis.

The practical measures recommended years ago were since tested in part, and so far as tested were found of use. These recommendations were:

1. The notification to and registration by health authorities of all cases of tuberculosis which have arrived at the infectious stage.
2. The thorough disinfection of all houses in which tuberculosis has occurred, and the recording of such action in an open record.
3. The establishment of special hospitals for the treatment of tuberculosis.
4. The organization of societies for the prevention of tuberculosis.
5. Government inspection of dairies and slaughter-houses and the extermination of tuberculosis among dairy cattle.
6. Appropriate legislation against spitting into places where the sputum is likely to infect others and against the sale or donation of objects which have been in use by consumptives unless they have been thoroughly disinfected.
7. Compulsory disinfection of hotel rooms, sleeping-car berths and steamer cabins, which have been occupied by consumptives before other persons are allowed to occupy them.

In addition to these specific recommendations, the committee urged on the public the importance of better housing of the poor in their places of abode and in their places of occupation; better control of the food supply at large, and more definite instructions in the schools and on the platform of diet for the working people. The home and workshop were really the centers from which the disease was distributed, and they at the same time were strong predisposing causes of the disease by reason of their unhealthiness. Bad and adulterated food and improper selection of food by the individual were also strong predisposing causes by lowering vitality. The committee suggested that every member act as a committee of one in his own home to help organize a campaign against this disease.

DISCUSSION.

DR. WALTER D. GREEN, Buffalo, N. Y., said that there were two things of special interest in combating the disease, one of which was notification of cases, and the other thorough disinfection of houses in which the disease occurred. In the city of Buffalo every house in which a case of tuberculosis develops is thoroughly disinfected. This has been the practice in that city for the last five years. A card index is of vital importance in keeping track of cases of the disease. The people should be educated in regard to the prevention and control of the disease. Pamphlets giving directions how to keep from getting the disease were printed in Buffalo in German, English, Polish and Italian. Directions were also given as to what to do when people contracted the disease.

DR. FRANK WARNER, Columbus, Ohio, said the reporting of cases of tuberculosis is an important factor in the prevention of the disease, but it is only the first step. Literature should be placed in the hands of families in which the disease developed. Information regarding the disease should also be published and put into the hands of men working in stores and shops. Articles relating to the disease should be published in the daily newspapers for the instruction of the public. The disinfection of houses after deaths had occurred in them is of great importance in order to destroy the germs of the disease. Testing for tuberculosis in cattle by tuberculin has proved a very important thing. At the Ohio State University there is an agricultural and dairy department, so that every cow is constantly tested with tuberculin for tuberculosis, and whenever the disease is found that animal is withdrawn from the herd.

DR. R. H. LEWIS, Raleigh, N. C., endorsed the position taken by the previous speaker. In his state pamphlets concerning the disease and its prevention are placed in the hands of superintendents of public instruction and of school teachers for distribution.

DR. MARCUS HAAS, Memphis, Tenn., referred to the thorough system of dairy and milk inspection in Memphis, from which gratifying results have been obtained.

DR. W. C. CHAPMAN, Toledo, Ohio, said that sanitarians should not demand too much of the physician, for in doing so they undo the benefit which they might otherwise receive. Physicians are reluctant in reporting cases of tuberculosis to city health departments, on account of the protests of families in which the disease occurs.

DR. MANUEL S. IGLESIA, Vera Cruz, Mexico, described the present hygienic conditions of that city, and expressed the hope that at no distant day this port would be one of the healthiest to be found.

DR. ARISTIDES AGRAMONTE, Havana. pointed out the practical utility of a medical board to aid local sanitary authorities in the investigation of infectious disease.

Diphtheria Infection in Minnesota.

DR. F. F. WESBROOK, Minneapolis, stated that in the work of the Minnesota State Board of Health the problems had arranged themselves into three main groups: First, the work of dealing with diphtheria as it occurs in family life, where one or more cases appear in a household; second, where infection was widespread and the day schools had to be closed; third, where infection gained entrance into institutions in which children or other inmates were housed, employed, taught or confined, and where great opportunity for the spread of infection was present. He said it was apparent that:

1. An adequate laboratory staff and equipment are essential, since only by thorough laboratory examination can the presence of possible danger be determined.
2. It has been found convenient to utilize institutional laboratories when available, as the members of the laboratory staff of the State Board of Health can examine cultures on the spot when there is urgent need of haste.
3. The repetition of examination of both nose and throat specimens is advisable in all cases, and especially when suspicious bacilli are found.
4. Every effort should be made to prevent the exchange of nose and throat bacteria between individuals until it is definitely known whether they are infected or not. In infected individuals the bacilli will be eliminated more quickly the greater the approximation to individual isolation.
5. It is unsafe to place hitherto uninfected individuals who develop sore throat with clinical cases of diphtheria.
6. Executive action must be taken on the basis afforded by the laboratory; therefore, it is essential that these two branches be kept in the closest touch, or that in the work of inauguration and supervision of methods a laboratory trained man be placed in charge.
7. That such methods give satisfactory results and are entirely practicable, has been shown in the experience of the Minnesota State Board of Health under conditions which presented the greatest possible variation. Three epidemics had thus been suppressed in a lying-in hospital in Minneapolis where there was no adequate nursing force, where the women before and after confinement were employed in the housework of the institution, where the babies were left in charge of different mothers at different times, and where also the almost daily admission of fresh inmates added to the opportunities for the introduction of infection.
8. The experience of Minnesota would seem to point decidedly to the conclusion that diphtheria infection is transmitted usually by almost direct exchange of flora of the nose and throat.
9. In institutional and school life the more independent the individual and the greater the facilities for individual infection, the greater the freedom from diphtheria infection.

DR. SAMUEL H. DURGIN, Boston, read the report of the committee on the infectious period of communicable diseases.

Social Hygiene.

DR. ADOLPHO OLIVA, Guadalajara, Mexico, pointed out the effects of dress on the system. He also discussed the various forms of dress. He said that variations in temperature of the system, with the climate, seasons, age, constitution, and the conditions of health or of disease fully demonstrated the physiologic necessity of dress.

Yellow Fever in Mexico.

DR. E. LICEAGA, Mexico, described how houses that were infected with the disease are disinfected. As soon as a case of yellow fever is found, the patient is isolated and the mosquitoes and larvæ are destroyed. The Vera Cruz campaign against yellow fever has been very successful, in that there has not been any epidemic of the disease in that city for the last six months. He cited one case to prove, without doubt, that yellow fever is transmitted by mosquitoes alone.

Control of the Milk Supply in Large Cities.

DR. WILLIAM H. PARK, New York City, chairman of a committee, read a report on this subject. The topic was considered under three heads: 1. The proper conditions at the farms. 2. Proper conditions during transportation of the milk, and 3. Proper conditions at the delivery station and in the case of the milk in the homes. Until recently the conditions at the farms have been largely overlooked by the health officers of great cities, on account of the practical difficulties and the expense. The milk commission appointed by the Medical Society of the County of New York has undertaken to assist both the consumer and producer by fixing a standard of cleanliness and quality to which it could certify, and by giving information concerning measures needful for obtaining that degree of purity. The most practical standard for the estimation of cleanliness in the handling and care of milk is its relative freedom from germs or bacteria. Milk must not be sold as certified more than twenty-four hours after its arrival in New York City. The report discussed the duties and requirements of dealers in milk, the barnyard, the stable, the condition of the cows, the milkers, helpers other than milkers, small animals, the milk itself, the utensils for holding milk, as well as the examination of the milk and dairy inspection.

DR. GONZALO AROSTEGUI, Havana, discussed the importance of good quality and careful distribution of the milk supply.

Infantile Feeding by Nurses.

Dr. Alfonso Pruneda, Mexico, said it is necessary always to advocate the need of maternal lactation, but in the event of this being found impossible, we should not hesitate to adopt some other methods. Avoid the employment of wet nurses, who, as the writer pointed out, present many objections, but rather make use of sterilized milk, which, when properly and methodically used, would fulfill its purpose, and thus save the lives of many children who would under other conditions perish and increase the infant death rate.

Production of Animal Vaccine.

Dr. W. F. Elgin, Glenolden, Pa., described experiments and detailed his experience in the production of animal vaccine. The author pointed out that: 1. Virus exposed to cold below O. C. might remain active for an indefinite period, certainly for several years. 2. When it is removed from cold storage, it will retain its activity for a considerable period under conditions that usually obtained commercially. 3. When glycerinated lymph is exposed to O. C., or below, the destruction of germ life through the action of the glycerin is practically at a standstill. 4. The rapidity of the elimination of the contained bacteria depends on the temperature above 10 degrees C., in which the virus is stored. He showed that the life of the average commercial vaccine is only three months in winter, and in August and September only about one month. Two lessons might be learned from this: First, one should not vaccinate in the summer season unless compelled to do so by the presence of smallpox. Second, when compelled to vaccinate at this season, one should order the vaccine direct from the laboratory, and use it at once without regard to the dating on the package.

The author stated that dried vaccine in any form was short-lived, and not nearly so reliable as the glycerinated form. The most active virus is to be obtained from the deep curetting.

DISCUSSION.

Dr. F. P. Bernaldez, Mexico, cited facts and arguments tending to demonstrate the superiority of humanized over animal vaccine for the prevention of smallpox. He claimed that persons who were vaccinated and revaccinated with humanized lymph enjoyed a longer immunity, according to his observations, and in Mexico he had never seen a case so vaccinated attacked by smallpox. His practice has taught him that in such persons revaccination did not take, or at most assumed the appearance of false vaccination, thus proving in his opinion that the individual was not susceptible. He urged that vaccination be practiced by physicians of experience in order to avoid the possibility of transmission of disease.

Dr. Vincente de la Guardia, Havana, spoke of the necessity of vaccination and revaccination of individuals who had suffered from smallpox. He said that in most countries there is no vaccination requirement for individuals who had had smallpox. He had had the opportunity of vaccinating and revaccinating 1,599 persons, members of the police department, custom house inspectors, port policemen, persons confined in jails, males and females, etc. Of this number, 328 were branded with the smallpox trademark, and of 47 vaccinated for the first time in their lives, 17 were successful in taking. Two hundred and sixty-three were revaccinated, in 48 of whom it took successfully, giving a total of 65 successful vaccinations. The total result of the 328 who had had smallpox previously corresponded approximately to over 20 per cent. of the total figures. He urged that, as a general rule, all individuals, whether they be ex-victims of smallpox or not, should be vaccinated or revaccinated, as the case might be.

Stegomyia Fasciata.

Dr. Fernando Lopez, Mexico, detailed some experimental studies on the acclimatization of this germ. The experiments seemed to prove that the *Stegomyia fasciata* could live, bite, and breed for at least three generations in Mexico City, notwithstanding the fact that this city has an altitude of more than 7,300 feet above sea level.

(To be continued.)

ILLINOIS STATE ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

Organized Jan. 19, 1905, at Chicago.

This meeting was attended by a large number of physicians, heads of charitable organizations, and professional nurses. The primary objects of the association are to impress the public with the importance of having a state sanatorium where consumptives may be properly treated, and to enact a law to compel cities, towns and villages to keep records of sufferers from the disease and of those who die from it, so that houses may be properly fumigated and disinfected. It is expected that an appropriation of at least $250,000 will be asked from the legislature. Governor Charles S. Deneen was made honorary president, and Dr. Edmund J. James, president of the University of Illinois, acting president, with Dr. Arnold C. Klebs of Chicago as secretary. The association voted in as affiliated branches of the main organization the Visiting Nurses' Association and the United Hebrew Charities of Chicago.

Dr. William E. Quine, who called the meeting to order, referred to the lack of general information on the possibility of curbing consumption, to the infection from sputum, and to the lax enforcement of local laws on this and relative subjects. While every case of tuberculosis can not be cured, it is safe to say that 75 per cent. of the cases in the incipient stages, if properly attended to and treated, can be absolutely cured. He referred to the tent colony in Ottawa, and stated that while it does great work, the accommodations are limited.

Dr. Arnold C. Klebs said that Illinois is far behind other states in the matter of protecting the public against the ravages of consumption. While the number of consumptives in the state is variously estimated from forty thousand to fifty thousand, there are only 563 beds for such patients in the whole commonwealth. He spoke of what Canada is doing in the way of furnishing hospitals for the victims of the disease, and said that the dominion in some respects is ahead of this country. He advocated the formation of societies in every village, town, and city in Illinois, for the intelligent study of the question and for co-operation with the state body.

Dr. William A. Evans said that while Chicago and other cities and towns have ordinances forbidding expectoration, these laws are not enforced, and disease is allowed to be spread broadcast. He pleaded for instruction to the public regarding better living conditions, and concerning more satisfactory conditions in factories and stores.

Dr. George W. Webster said that the Illinois State Board of Health is distributing literature on the prevention of consumption. More than 75,000 pamphlets have been sent out, and there is still a call for them from railroads and other corporations and business firms. Leaders in this movement have become convinced that Illinois should follow the lead of Massachusetts, New York and Rhode Island in the establishment of a state sanitarium. Investigation reveals that there are constantly as many as fifty thousand consumptive patients in Illinois, while Chicago alone averages about twenty thousand. Each year about one-fifth of the victims die, the number in Chicago last year being 3,500, so far as known. It is learned that many cases of consumption are not reported, and that physicians in some cases say the patient died of pneumonia. Taking Chicago's mortality from consumption in 1000 for a basis, figuring the loss of the individual's service per day at the low rate of $1.00, and expenses and maintenance, nursing and treatment at $1.50 additional, it is found that the cost to the city of Chicago caused by the death in one year of 2,682 tuberculous persons amounts to the startling sum of $2,011,500.

The executive committee consists of the president and secretary of the association, ex-officio, Dr. Wm. E. Quine, Dr. J. W. Pettit, Dr. George W. Webster, Ernest P. Bicknell, and Sherman C. Kingsley. The central committee comprises Drs. Wm. E. Quine, Frank Billings, N. S. Davis, Joseph E. Milligan, N. B. Delamater, N. A. Graves, George W. Webster, W. A. Evans and Robert H. Babcock, and Mr. Ernest P. Bicknell.

CHICAGO SURGICAL SOCIETY.

Regular Meeting, held Dec. 5, 1904.

The President, Dr. L. L. McArthur, in the Chair.

Actinomycosis.

DR. ARTHUR DEAN BEVAN referred, first, to the early history of this disease, saying that von Langenbeck first noticed the sulphur-green bodies of actinomycosis as early as 1845, and that Bollinger recognized the ray fungus in lumpy jaw in cattle. Israel, in 1878, recognized the ray fungus as the cause of the disease in man. Belfield first recognized the ray fungus in lumpy jaw in cattle in this city, and Murphy reported the first case of actinomycosis in man in this country in 1883. Clinically the disease appears in four different forms, with four different groups of infection: 1, The head and neck actinomycosis, with infection from the mouth and pharynx; 2, actinomycosis of the chest through the respiratory tract; 3, abdominal actinomycosis, with infection probably always through the alimentary canal, possibly, however, in rare instances, through the female genital organs; 4, actinomycosis of the skin. The lymphatic glands are seldom involved, but he reported one case in his group of cases in which there was invasion of the lymphatics. Dr. Bevan reported cases illustrating each form of the disease, and showed numerous microscopic slides.

DISCUSSION.

DR. JOHN B. MURPHY said that an important feature brought out by the essayist was the demonstration of lymphatic involvement. In none of the cases that came under his observation was it shown that the lymphatic glands became involved, or that the infection was transmitted through the lymphatic chain and arrested in the lymphatic glands. Another point was the enormous infiltration that occurred around a small focus of suppuration. This is one of the first things that attracted Dr. Murphy's attention in the first case of actinomycosis he saw, in 1883. This was a typical case of actinomycosis of the jaw, in which the infiltration involved the neck to the extent of an inch or more on each side. There was apparently a small fluctuating focus. When the involved area was opened a number of yellow bodies escaped. These appeared molded. They were neither round nor oval. The infiltration described by Dr. Bevan in his case of actinomycosis of the pelvis was one of the classical conditions of the disease in the peritoneum. While the disease affects all the tissues, it elects fatty tissue, involving skin, muscle or bone, lifting its periosteum, attacking the periosteum, or sometimes attacking the fatty tissue close to the periosteum without attacking bone. Dr. Murphy's first, second and third cases recovered, but the fourth, one of peritoneal actinomycosis, terminated fatally. There was no perforation of the stomach wall nor of the large intestine, but there was infiltration of the fatty tissue on both sides, the micro-organisms having passed up into the diaphragm and beneath the surface of the liver. He has also seen two cases of actinomycosis of the appendix. In the first the actinomycotic process was confined practically within the appendix. The appendix was extirpated and the patient recovered. The second case pursued an entirely different course, although death has not yet occurred.

DR. E. WYLLYS ANDREWS said that the large percentage of recoveries referred to is quite contrary to his own experience. Most of the cases he has seen have either died or, if they were living, there is an increasing actinomycotic mass in other parts of the body. He recalled one man who has a mass in his chest, and who, he thinks, is going to die. An analysis of all the cases of actinomycosis of the alimentary canal would scarcely disclose one involving the stomach, and the probabilities are that the acidity of the stomach prevents the active generation of the germs there. A comparatively small number are found in the upper intestine. In nearly one-half of all cases reported the actinomyces are found in the cecum and in the appendix. He has not seen a case of actinomycosis involving the rectal region.

DR. M. L. HARRIS has seen during the past year three cases of actinomycosis, which apparently were hematogenous infections. The first case was in a country boy, who was admitted to the hospital with a slowly-developing swelling in the prevesical space. It had the characteristic hardness. He opened the mass and obtained a small amount of pus. Inoculations from the pus gave a pure culture of *Staphylococcus pyogenes albus*. In the first pus which was evacuated no granules were recognized, but on the dressings, a few days later, the characteristic granules were at once recognized, and when examined microscopically they were demonstrated to be actinomyces. The case progressed, sinuses and fistulæ were formed about the abdominal wall and into the lateral wall of the pelvis. The boy was operated on several times, these tracts thoroughly cleared out, and during the operations the abdominal cavity was opened, because the speaker was suspicious of a primary intestinal origin. The abscess did not originate in the appendix, nor could he find any point of the intestinal tract that was involved. He was unable to explain how the infection reached the prevesical space, except through the blood. The patient was subjected to all the recognized treatments for actinomycosis. Iodid of potash was given internally continually and interruptedly. He was given *x*-ray treatment very thoroughly, but in spite of all treatment he became progressively worse, and after a period of several months died. A peculiarity in this case was the very marked reduction of hemoglobin. The red cells were not reduced in number, but the hemoglobin was reduced to a low point before death. Dr. Harris said that all three cases seemed to be instances of hematogenous infection, the organisms having been carried in through the blood, as there was no local point of infection, so far as he could determine.

DR. A. J. OCHSNER said there are a great many cases of actinomycosis in Chicago and its vicinity, although most of them have not been accurately diagnosed. He is almost never without a case of actinomycosis. He has one under treatment at the present time. He recalled half a dozen cases in which the face and neck were involved; one in which the larynx was affected; in a number the abdomen was involved; in one the eighth rib, and in others the appendix. He has had two or three cases of actinomycosis of the lungs. He believes surgeons should follow the method of veterinary surgeons if they wish to succeed in treating this disease. In late cases of actinomycosis in cattle the veterinary surgeon has the animals killed. He never tries to cure a late case of this disease in cattle. In the early cases, however, an effort is made to remove the entire mass by thorough curettage, followed by the administration of large doses of iodid of potash. Veterinary surgeons give a large quantity of iodid of potash for several days in succession and then they interrupt its use, giving the spores time to develop into ray fungi, after which they repeat the dose for a day or two, then withdraw it for a day or two again, repeat it again, and so on, and in cases where the actinomycotic process is localized the cattle recover. Actinomycosis in the human being should be treated on the same principles. About eight or nine years ago the speaker followed the method of giving iodid of potash in increasingly large doses, but in several cases in succession there was apparently no effect on the disease until he reached the dose of a dram three times a day, and then the progress of the disease became arrested. His first case impressed him with the importance of giving large doses of iodid of potash. It was a case of actinomycosis of the scalp. The disease burrowed and burrowed, and every week or so he found it necessary to scrape the scalp and apply every remedy he could think of, without much improvement. However, when he reached 60 grains of iodid of potash three times a day the disease was arrested. The next case he had acted in a similar manner, and since then he has made it a rule to give 90 grains of iodid of potash in a half pint of hot milk at 2 in the morning, 2 in the afternoon and 10 at night, for as many days as the patient can stand it. After a week it is withdrawn for some days, when it is repeated for three or four days, withdrawn again, and later repeated once a month. The reason why he repeats iodid of potash once a month is that in one of his fatal cases he did this for a time and the patient was apparently well, but two years later the patient had a recurrence and died of the disease. A circumscribed encysted abscess was found at autopsy in the lower end of the right pleura.

Dr. L. L. McArthur reported the case of a young woman, very fond of golf, who frequently was rebuked by her husband for chewing hay while playing golf. She developed actinomycosis of the alveolar process, which required three or four months' treatment by a dentist before it healed. Nine or ten months later she began to have pain in the right iliac region, and this pain being of a rather colicky character, she consulted her family physician, Dr. Carey, who, feeling a mass there, and noticing that she had elevation of temperature, sent her to Dr. McArthur's service at St. Luke's Hospital, believing it to be a probable appendiceal abscess. Dr. McArthur concurred in this diagnosis and advised operation. On opening the abdomen a tumor was found in the ileocecal region, involving the appendix, ileum and cecum, for a distance of four or five inches on the cecum. The tumor in its clinical aspect, although having no miliary bodies on it, seemed to him to be a hypertrophic tuberculosis, and on that basis, with the consent of the family physician, he made a resection of the entire ileocecal region, implanting the resected ileum in the side of the hepatic flexure of the colon. On lifting this mass up from the iliac fossa a few drops of pus were seen on the fascia covering the iliac muscles. This was mopped up, drainage provided for and the wound closed. The wound healed after a few weeks, the patient left the hospital, and for three months was quite well, when she began to have a cough and high temperature, with chills and night sweats. During his absence from the city she was seen by his assistant, Dr. Hollister, who considered the case—although he was unable to demonstrate tubercle bacilli in the sputum—one of acute tubercular trouble, the patient having lived in the house of a patient who had died a few months before of tuberculosis. On Dr. McArthur's return he saw her and found a tender area, with an enlargement in the neighborhood of Spigelius' lobe of the liver, and considered the condition one of hepatic abscess with burrowing through the diaphragm. He urged operative interference. The husband refused to have any operation performed until she had become extremely run down and had a temperature varying from 103 to 106 F. for three or four weeks. The patient was brought to the hospital, an incision was made over this area, and he found an abscess which had perforated the posterior sheath of the rectus muscle, and in which were then to be seen for the first time the typical granules, and the nature of the case became clear. The patient lingered along for about two weeks and finally died. A careful postmortem examination was made by Dr. Hektoen and a very thorough report of the case was made. In the sputum there were found the typical leptothrix-like threads, but never any suspicion was had of granules. In the stomach abscess opened there were typical granules to be found, and from them cultures were made which proved characteristic, so that here was a person in the habit of chewing grain and hay, who had disease of the jaw, who had a hypertrophic actinomycotic infection, which often is indistinguishable from tuberculosis, who recovered from that and later developed hepatic abscesses, with perforation of the diaphragm. Postmortem examination showed multiple stomach abscesses burrowing into the diaphragm and miliary abscesses along the bronchi.

CALIFORNIA ACADEMY OF MEDICINE.

Meeting held Dec. 27, 1904.

Dr. Dudley Tait in the Chair.

Unilateral Pulsus Paradoxus.

Dr. A. W. Hewlett exhibited a patient presenting a one-sided pulsus paradoxus. About eighteen months previously he had suffered from an acute illness, at the close of which the left side of his chest was noticed [illegible] be much smaller than the right side. At the present time the air enters only the upper front of the left chest, the remainder of this side being much retracted, flat on percussion and without breath sounds. The left pulse is normal, showing on deep inspiration a slight quickening accompanied by a slight diminution in the size of the individual beats. On deep inspiration the right radial pulse disappears entirely and does not return as long as the position of deep inspiration is maintained. If the right shoulder is passively elevated, however, the pulse does not disappear on deep inspiration. The brachial and axillary pulses disappear with the radial, but the subclavian above the clavicle continues to pulsate under all circumstances. The artery is, therefore, pressed out as it crosses beneath the clavicle, possibly between the clavicle and the first rib or by the fasciæ.

Dr. Ophüls suggested that the disappearance of the pulse might be caused by an inspiratory dragging on the heart or blood vessels by adhesions and that this might cause a kink in the subclavian artery as it crossed the first rib.

An Epidemic of Diphtheria at Stanford University.

Dr. R. L. Wilbur reported his personal experience in the recent epidemic of diphtheria at Stanford University and the neighboring town. The origin of the epidemic could not be definitely traced. Of the 43 cases which came under his observation, in four the infection involved the larynx; in three the mouth; in one the nose, and in one the conjunctiva. No deaths occurred and no intubations were necessary. It was often possible to make an early diagnosis by the use of a throat mirror and probe, thereby discovering small exudates on the tonsils which might otherwise have been overlooked. Cultures were made and in no case was a positive diagnosis made until the cultures were positive. Subnormal temperatures and slow pulse rates were frequent in this series. All patients with but one exception were treated with large doses of antitoxin, 4,000 to 36,000 units being given. The initial dose was 4,000 units, and this amount was repeated within six to eight hours unless marked improvement had followed. The results of the antitoxic treatment were often immediate and most striking, so much so that the correctness of the diagnosis might have been doubted in some cases had no cultures been made. Of 287 persons exposed to the disease and who received prophylactic doses of antitoxin, only one developed diphtheria and he had received only 500 units, whereas 1,000 were usually given.

DISCUSSION.

Dr. G. H. Evans approved of large doses of antitoxin. He said that since the introduction of antitoxin he had noticed many more rashes accompanying diphtheria, and believed that these were due to the use of the new treatment.

Dr. Wilbur stated that he believed that the rash frequently resulted from the antiseptics added as preservatives to the serum. He has noticed that the serum put up by certain manufacturers seems more liable to cause rashes than that put up by others.

Abortive Treatment of Gonorrhea.

Dr. George Gross reported a case of gonorrhea which was aborted by the use of Engelbreth's method. The patient was seen three days after coitus and gonococci were demonstrated in the slight discharge. The anterior urethra was irrigated with 500 c.c. of a .5 per cent solution of silver nitrate under a pressure of 1.25 meters, and the fossa and meatus were swabbed with a 3 per cent. solution of the same salt. Six hours later the irrigation was repeated, using a .2 per cent. solution of silver nitrate. In the pus examined six hours after the first irrigation no gonococci were found and they remained permanently absent. The discharge had ceased entirely by the end of four days. The treatment caused some pain, but less than one would expect.

DISCUSSION.

Dr. R. L. Wilbur *said that* there was danger of doing harm by the use of abortive treatments for gonorrhea.

Dr. Gross replied that these dangers were *minimized* by the use of large quantities of a *relatively* dilute solution, administered under a known pressure, thus eliminating the danger of having the irrigating fluid enter the posterior urethra.

Travel Notes.

FOUR THOUSAND MILES THROUGH INDIA BY RAIL IN MIDSUMMER.

NICHOLAS SENN, M.D.
CHICAGO.

(*Continued from page 242.*)

NOTABLE MEDICINAL TREES OF INDIA.

On landing at Tuticurin I came face to face with two trees that I never lost sight of on my long railway journey—the palmyra palm and the nim tree. The palmyra palm (*Borassus flabelliformis*) is a hardy, noble tree, and attains a height of 100 feet. The base of the stem is large and gradually tapers into the stem proper, which has a uniform thickness up to the very crown. The bark is almost black and indented with circular rings. The crown of fronds is small compared with the size of the tree. In southern India the leaves are used for roofing, and nearly all the trees have been pruned down to six or eight fronds. The pulp of the fruit serves as food. Enormous masses of sugar and toddy are produced in India from the sap which flows from incisions of the stalk of the unexpanded flowers. This tree is noted for its longevity, and trees 200 years old are by no means rare. The Mohammedans are supposed to be total abstainers, but not invariably so, as I learned from a little story related to me in India. A man who owned a number of these palm trees, and who had bled them for the purpose of supplying himself with the much cherished toddy, noticed that much of the precious juice disappeared mysteriously during the night. Not suspecting that the pilfering was done by human beings he poured aconite into the cuts into which the sap accumulated. The next morning in going for his toddy he found to his utter astonishment two followers of the prophet dead near the tree and several more very sick in an adjacent thicket. For obvious reasons a judicial investigation was not applied for. The leaves of this palm have been used for centuries as writing paper.

The nim tree (*Melia azadirachta*) is one of the most beautiful and useful trees of India. It attains a height of 50 feet, has a short, black barked stem, strong, widely spreading branches and a dark, fresh green, rich foliage of long feathery leaves. At Jaipur I saw a boy climb one of these trees, and with pruning scissors sever enough of its leaves to feed a flock of sheep which had gathered around the base of the tree. anxiously awaiting the expected fodder. The leaves have a great reputation as a remedy for dysentery and malaria. Many wonderful stories have I heard concerning the curative powers of a decoction of the leaves of the nim tree. This popular reputation is sustained by the medical profession.

The tamarind (*Tamarindus india*) is a magnificent, large, expansive tree. It is one of the largest trees of southern India. An immense tamarind tree is in the court of the monkey temple at Benares, and it is in this tree that the monkeys take their gymnastic exercises. The monkeys are anxiously awaiting the ripening of its fruit. The acid pulp of the long pods forms the medicinal tamarind, rich in formic and butyric acid, irrespective of its other contents, cold made into a syrup. it can be kept for preparing a palatable acidulous drink.

The bábul or gum arabic tree (*Acacia arabica*) is a very common tree in India. It is a small tree and is used sometimes for thorny hedges. Occasionally the stem attains a circumference of 10 feet. It furnishes one of the best kinds of gum arabic for medicinal and technical purposes. Cattle are fond of its leaves. The wood is hard and durable, and the pods and bark are used for tanning. One of the most interesting trees in India, although without medical interest, is the banyan tree (*Ficus bengalinsis*). While at Calcutta I made a special pilgrimage to see the famous banyan tree in the Botanical Garden, six miles from the center of the city. A label attached to the stem of the mother tree bears the following legend: "This tree is about 135 years old; the circumference of its trunk, at about 5½ feet from the ground, is 51 feet, and of its crown about 938 feet. It has 464 aerial roots actually rooted in the ground." The sight of this veteran of the Botanical Garden is inspiring. The daughter trees form a circular colonnade and their interweaving branches a roof under which a whole regiment of soldiers would find an ample camping ground. The mother tree shows signs of far advanced senile decay, but her offspring have gained an independent existence and will keep her memory fresh for many generations to come. Since I saw this wonder of the Indian forests I have learned that the banyan tree at Ahemabad is still larger and the largest in the world. Had I known this before I would have intercepted my itinerary at that ancient city.

For technical purposes, the most valuable tree in India is the teak tree (*Tectona grandis*). It is a superb timber tree. It sheds its very large leaves annually. Teakwood is held in the highest esteem by shipbuilders; for the backing of ironclad men-of-war it is preferred to any other wood; also for the panels of coaches and inside finishing of houses, and for various other select purposes. The wood is extremely hard and scarcely shrinks. This wood is sold in London at $75 per 50 cubic feet.

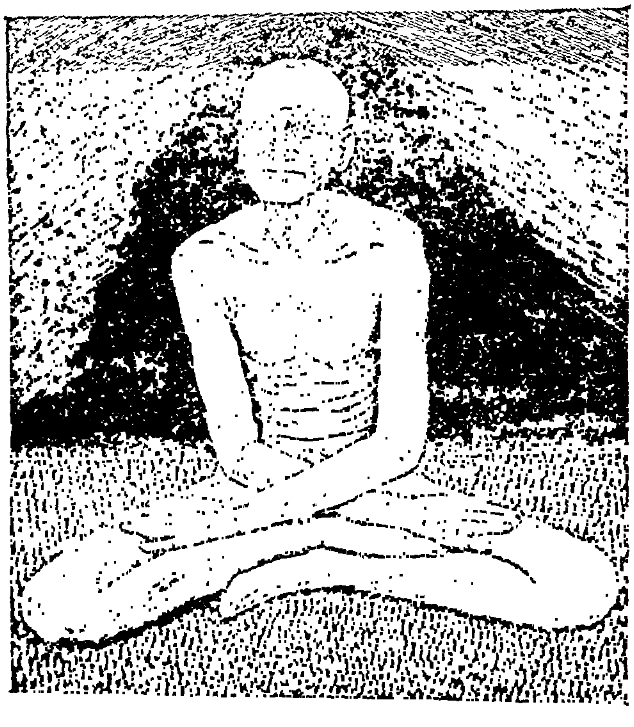

Fig 3.—Swami Bhaskara Nand Saraswati, the famous Ascetic of Benares.

The siris-acacia (*Albizzia lebbeck*) is a very common and beautiful shade tree. It produces also a good deal of useful gum. The blossoms are much sought by honey bees, as their pollen is rich in honey-producing material.

BENARES MONKEY TEMPLE.

Among the many things which interest the traveler at Benares is the Monkey Temple. Within the walled enclosure surrounding the temple is an immense tank which collects the rainwater. From the tank a series of wide stone steps lead to the famous temple. On entering the temple, we were met by the chief priest, Sree Swayam Prakashhashanand Maithila Auland Bag, the successor of the Benares saint recently deceased. His dress did not indicate his high Brahmin position. It consisted of a loin cloth and a few yards of yellow calico with which to obscure the left arm and a very limited part of the chest. His short-cropped, grizzly hair and beard did not add much to his clerical appearance.

The moment we entered half a dozen young priests who surrounded him howled at the top of their voices, how, how, how. I thought I had committed a blunder by entering the sanctuary in my mud-stained shoes. This was not the case. It was a priestly greeting and a call for the monkeys, which came running from all directions, knowing well that the call meant the arrival of a stranger who would be willing to part with a few small silver coins, with some of which the good priests would buy food for them which they expected to eat in the presence of the visitor. They had calculated right; their expectations were realized. These miserable, treacherous, thievish, filthy beasts occupy a high position as objects of worship by the Hindus. To maltreat a monkey constitutes, in their estimation, a greater crime than the killing of a coolie. The monkeys in this temple are the same as the herds of monkeys in and all around Jaipur. They are very large, gray, with a black face and a tail as long and as thick as a broom handle. In a few moments we were surrounded by a large crowd of these pets of the priest, with whom they are very familiar, but they mistrust the white man and remain at a respectable distance from him. They eagerly devoured the proffered food, roasted peas and small crackers. The majestic tamarind tree behind the temple was alive with monkeys of all sizes and ages. Veteran monkeys of doubtful age and baby monkeys on the backs of their mothers, were all equally anxious to be benefited by the liberality of the visitor, as visitors during this season of the year are of rare occurrence. There are more than 300 of these monkey gods in this temple.

A BENARES SAINT.

The priest to whom I have first referred is, as he claims, the legitimate successor to the Benares Saint, Swami Bhaskara Nand Saraswati. (Fig. 3.) He has the advantage over his predecessor in the greater length of his name. The saint, or, as his successor calls him, "Holy Sage," died a few years ago and I visited his plain tomb near the temple. He was for many years a familiar Benares character. His deep learning, plain manner of living and ascetic disposition made him prominent in the priesthood and an object of curiosity to the visitors. He was born in the year 1833. He was invested with the sacred thread when he was 8 years old. He married at the age of 12 but left no issue, although a son had been born to him. Soon after the birth of his child he left his home and wife and devoted himself to the study of Sanscrit, visited shrines and became known to all as a profound Sanscrit scholar, a philosopher and a real Yogi. His successor says of him: "His dignified mien and venerable face silenced the onlookers who had doubted that a man could learn and practice Yoga at such an early age." And again, "His soul penetrated into the very heart of Being, by seeing reality as it is. He was a philosopher to whom God was not merely the creator of this universe, its protector and guide, but the life of his life, the soul of his soul—his very self. Such a sage was the Swami Bhaskara Nand—calm, silent, majestic, immersed in the glory of his own soul." What an enviable record to leave in this world of sin and corruption.

HINDU CREMATION.

Sitting on the deck of a river rowboat and gliding down the sacred Ganges near its border on the side of the ancient city of Benares, we passed the principal temple. I saw a number of burning funeral pyres at the very edge of the turbulent, dirty stream. It was too late to see the whole process of cremation as practiced by the Hindus. It was at Agra that I was given an opportunity to become a witness of this funeral rite. On the way to the Taj Mahal we passed a small procession, following a corpse carried on a litter of dry bamboo sticks on the shoulders of four men. The corpse was covered with a cloth of bright colors, red being the predominating one. The whole procession was made up of men, 24 in number. Women never attend funerals. The procession moved in quick steps and the mourners chanted a monotonous dirge, repeating over and over the same words, which the guide translated into "The name of God is true." Wishing to profit by this opportunity to witness an open-air cremation, I abandoned, for the time being, the visit to Taj Mahal and followed the procession. The procession continued its march until the border of the Jumna River was reached, where the corpse resting on the bamboo litter was deposited on the ground. I learned that the body was the corpse of a married coolie woman, 25 years old. She was sick 15 days with a diffuse swelling of the face (erysipelas?), and had died at 5 o'clock in the morning of the same day. It was now 9 a. m. Her husband was working in a place in the country, 20 miles from the city, and knew nothing of her illness and death. The only relative present was a brother, a lad about 17 years old, who officiated at the ceremony. The people were evidently extremely poor, so economy had to be practiced in cremating the corpse. The men squatted in a group on the banks of the river, smoked and chatted, and nothing but the presence of the corpse and the materials for building a fire reminded us that we were in the presence of death. The young brother was the only one whose face was earnest and expressive of grief, but not a tear was to be seen. Wood is very expensive in India, ¼ pie a pound (1/16 of a cent), hence it was used sparingly in this cremation. About two armsful had been procured. A pile of round dry chips, each about the size of a soup plate, was to be the principal fuel. These chips are made of stable manure mixed with rice straw. In the soft state, they are attached to walls and the outside of houses, where they are dried in the sun, and are used extensively as fuel. They are the prototype of the "buffalo chips" of our western prairies. The ground was first covered with several layers of these chips over an area a little in excess of the width and length of the corpse; pieces of dry wood were then laid across. The body was then prepared by the brother; the highly colored cloth was removed; the face was wrapped in a cloth and was never exposed while the brother washed it with water dipped from the nearby Jumna. Next the glass bracelets were broken with a piece of wood. The body, in a cheap, well-worn calico dress, was placed on the layer of wood and, lastly, chips were piled on all sides and over the corpse. A small bundle of dry brush was then purchased, for four annas, and distributed over the sides and top of the small mountain of chips. A handful of rice straw was then taken from the litter, twisted into a torch, ignited by one of the old men, swung by the brother until it burned in a bright flame, and with this the dry brush was set afire at the head of the corpse. The breeze was in the right direction, and in a few moments the entire pile was ablaze, the chips caught fire and soon the odor of burning flesh escaped with the smoke. It was at this stage of the cremation that I was as anxious to leave as I had been at first to witness it. We left the mourning party jabbering, laughing, smoking and looking lazily and unfeelingly into the smouldering fire maintained by the chips. During our stay, the ashes of the two corpses previously cremated were thrown into the Jumna River. On a knoll overlooking the river a Brahmin priest. was perched, awaiting the funeral procession of a corpse attended by mourners who could pay him for his priestly functions. He did nothing for the poor young woman whose corpse was now being devoured by the smouldering fire furnished by the cheapest fuel. He did not have to wait long to assist in the happy incarnation of the soul of one of his faith. In returning to the city we met another funeral procession, chanting the same funeral dirge, but to outward appearances the mourners belonged to a higher cast. They were well dressed and undoubtedly expected to pay the priest liberally for his services.

> "It is a brief period of life that is granted us by Nature, but the memory of a well-spent life never dies."—Cicero.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of Vaginal Gonorrhea.

The difficulties to be encountered in the treatment of vaginal gonorrhea, according to Dr. Daniel in *Med. Press*, are the peculiar anatomic structures of the female genital organs and the multiplication of microbes in the different segments of the uro-genital apparatus. Its oblique direction downward and forward renders the vagina difficult to disinfect. The treatment should consist of irrigation of the vulva, cervico-uterine, urethral and vaginal tracts. In very acute cases irrigations should be administered, consisting of six quarts of boiled water or a solution of potassium permanganate (1 to 10,000), associated with prolonged baths. After the acute stage has passed the treatment should be as follows:

The whole region inside and out should be washed with soap and warm water by means of a vaginal brush or sterilized wool, followed by rinsing the vagina with simple boiled water, and this followed by an injection of six quarts of warm potassium permanganate solution (1 to 4,000). The vagina should then be plugged with five or six plugs of sterilized gauze impregnated with the same solution. After twenty-four hours the plugs should be withdrawn and the injection repeated as before, followed by fresh plugs. These may then be permanently removed after twenty-four hours. The irrigations should be continued two or three times a day for ten or fifteen days. The os uteri should be painted every two days with a solution of silver nitrate (1 to 100). A pencil of the nitrate should be introduced into the urethra and immediately withdrawn every eighth day, for one month.

Gastric Vertigo.

The treatment of vertigo due to gastric disturbances, according to A. Robin in *Amer. Med.*, consists in directing the patient to take a cup of tea before arising to which has been added 30 grains (2.00) of quassia. The quassia is permitted to macerate in cold tea for two hours before it is drunk. The breakfast should consist of soft-boiled eggs, toasted bread and stewed fruit. No liquid should be given and the only liquid at other meals should be plain water or alkaline waters. No butter, fats, sauces, stews, fat fishes, pork, preserves, pastry, sweets, salads, raw fruits nor acids are permitted. Thin soup, broiled or roasted meat or fowl, vegetables, stale bread, eggs, boiled fish, stewed fruits and rice pudding should constitute the diet.

The tincture of nux vomica is prescribed in five-drop (.30) doses after each meal. And after lunch, dinner and before retiring the following powder is recommended:

℞.	Magnesiæ calcinæ	gr. v	30
	Sodii bicarb	gr. v	30
	Cretæ preparatæ	gr. viiss	50

M. Fiat chart. No. i. Sig.: One such powder after lunch, dinner and before retiring.

The bowels should be regulated by the following pill:

℞.	Aloes (cape)	gr. i	06
	Cambogiæ	gr. ss	03
	Ext. belladonnæ	gr. 1/12	005
	Ext. hyoscyami	gr. 1/12	005
	Ext. glycyrrhizæ	gr. ss	03

M. Fiat cap. No. i. Sig.: One such pill at bedtime for bowels.

If an attack of vertigo comes on the patient should be given the following combination:

℞.	Pulv. serpentariæ	gr. iiss	15
	Pulv. camphoræ	gr. 1/4	015
	Asafœtidæ	gr. 1/4	015
	Extracti opii	gr. 1/40	0015

M. Fiat cap. No. i. Sig.: From three to six pills, to be taken at intervals during the twenty-four hours.

In cases of extreme nervousness the following is recommended:

℞.	Potass. bromidi	ʒiss	6
	Aq. laurocerasi	ʒiiss	10
	Elix. simplicis q. s. ad	℥iiss	75

M. Sig.: One tablespoonful when an attack is threatened.

Hemoptysis.

The treatment of sudden and severe pulmonary hemorrhages, according to E. Hyslop Thomson in *British Medical Journal*, consists in producing conditions which favor the formation of a clot at the seat of hemorrhage by:

1. Diminishing the frequency of heart and lowering arterial tension.
2. By increasing the coagulable power of the blood.
3. By lessening the supply of blood to the diseased area.

To accomplish these conditions he advises that the head and shoulders be elevated and that a hypodermic injection of morphin grain 1/6 to 1/3 (.01 to .02) be given, and that from thirty to forty grains (2.00 to 2.65) of calcium chlorid dissolved in a small amount of water be given as a high injection. An icebag should be applied to the chest and heat to the lower extremities.

The value of morphin, according to the author, consists in its stimulating the inhibitory center and slowing the heart's action. The calcium chlorid is of great service because, first, the active fibrin ferment is rich in calcium, and wherever coagulability takes place calcium is present; secondly, the conditions which favor coagulability in the lungs are feeble, for blood, after it has circulated several times through the pulmonary vessels without entering the systemic circulation, loses its power of coagulability.

The writer also states that in excessive menstrual flow the injections of ergotin are valuable and that heat should be applied to the lower abdomen. He has not seen such valuable results from the administration of adrenalin in hemorrhages.

Silver Nitrate in Purulent Ophthalmia.

The treatment of purulent ophthalmia, according to Scrini in an abstract in *Amer. Med.*, consists in thoroughly removing the secretions from the lids by means of absorbent cotton and the application of the following lotions:

℞.	Potass. permangan	gr. v	30
	Aquæ dest	Oii	1000

M. Sig.: To be used as an irrigation to the lids.

Three or four hours later the following should be applied locally:

℞.	Argenti nitratis (crys.)	gr. iii	20
	Aquæ dest.	ʒv	20

M. Sig.: To be applied locally by means of an applicator. This should be neutralized by a solution of sodium chlorid.

If a 1 to 2 per cent. solution of silver nitrate gives *no* relief in two or three days it should be increased to 4 or 5 per cent. In case of corneal infiltration or ulceration, the silver nitrate should not be allowed to come in contact with the cornea. In such cases the following ointment should be applied:

℞.	Iodoformi (dissolved in ether)	gr. iv	25
	Vaselini (neutral)	ʒiss	10

M. Sig.: Apply locally.

If perforation seems probable, instill a few drops of a 4 per cent. solution of atropin into the eye.

Leg Ulcers—Varicose and Others.

TREATMENT OF VARICOSE VEINS.

The principles underlying the treatment of varicose veins, according to W. C. Rucker in *N. Y. Med. Jour.*, are:

1. The relief of pressure from within the veins.
2. The upbuilding of the general health.

The first may be accomplished by palliative or radical means, and the second by proper attention to diet, regulation of the bowels, and the administration of iron, arsenic and similar tonics.

The palliative measures consist in elevation of the leg and the fitting of an elastic stocking. This treatment is of benefit in those cases where the patient refuses an operation and in those in which for some reasons an operation can not be performed. However, according to the author, if a case is not far enough advanced to require an operation, no treatment is necessary, and if an operation is indicated by the conditions present, then other lines of treatment are useless. He, therefore, suggests that the saphenous vein be ligated to remove the weight of blood from the peripheral blood vessels, especially when the deep veins are involved and when the superficial veins alone are involved, multiple incision and ligation should also be done.

VARICOSE ULCERS.

Varicose ulcers are best treated by keeping the ulcer clean and stimulated, and by elevating the limb in addition to the above treatment. In order to render it impossible for the patient to lower the limb he should be put to bed, with the leg bandaged to a long posterior splint, which should be fastened to a box tied in the bed, as elevation must be constant in order to produce the proper results.

In order to cleanse and stimulate the ulcer the patient should be given an anesthetic and the wound thoroughly scrubbed with a brush, using a mixture of calcium chlorid, acetic acid and water, followed by a dressing of oiled silk, sterile gauze and a bandage applied from the toes to the knees. As soon as granulations have been established skin grafting should be performed.

This method, according to the author, is more rapid and certain than the use of various antiseptic powders, ointments, etc., as in wounds of low vitality antiseptics have a tendency to destroy granulations.

CHRONIC LEG ULCERS.

Blankenship, in the *Mobile Med. and Surg. Jour.*, says that in the milder cases of chronic leg ulcers rest, applications of various antiseptic and antiphlogistic remedies, accompanied by constitutional remedies and tonics may be all that is necessary. Strict cleanliness of the parts should always be carried out. Of the milder remedies he believes that one of the best is a weak solution of chloral hydrate (2 to 5 grs. to the ounce of water) applied on lint, with which he has had very good results in some cases. The more severe cases require more heroic treatment.

If inflammation is present, it should first be reduced by rest and appropriate means. Ichthyol applications are good for this purpose. One of the most common and perhaps one of the best methods is the adhesive plaster strappings of Baynton. This acts by affording support and compression, two of the cardinal principles in treatment of these cases, but if there is much discharge the strips would have to be removed so often that it would not answer very well. The best and most heroic plan, though it may confine the patient to his bed or to the house for five or six weeks, Blankenship believes, is in the long run the shortest course.

The method pursued is this: After a short preliminary treatment designed to disinfect the ulcer as much as possible and to reduce inflammation, the patient is given a general anesthetic, the ulcer and surrounding parts are scrubbed with a stiff nail brush and soft soap, then thoroughly curetted with a sharp curette, removing all the soft diseased tissue down to the hard, dense cicatricial base, exploring any pockets and scraping them. Then, with a scalpel, he makes incisions through the base and edges of the hardened fibrous tissue, cutting nearly or quite through the same. He crosses the incisions. If there is hemorrhage, it is stopped by hot water and pressure. With a mop of absorbent cotton he lightly and quickly touches the entire surface with pure carbolic acid, following it immediately by alcohol to limit the caustic action. He uses this not merely for its antiseptic action, but because it deadens pain. The patient does not suffer from pain after the operation. He fills the wound with boric acid in powder or scales, and applies a sterile gauze and cotton dressing, held firmly in place with a gauze bandage. If there is not much oozing this is allowed to remain on for two days. The subsequent dressing consists of cleansing with hydrogen peroxid in 50 per cent. solution and a dry dressing of an antiseptic powder combined with ichthyol, sterile gauze and cotton with bandage. If the granulations become too exuberant Blankenship uses nitrate of silver. Under this treatment there is usually a complete cure in from four to six weeks. The patients can be allowed to walk around the house a little after three or four weeks.

Eczema in Infants.

Zinc oxid is, as a rule, the best application in the treatment of moist eczema especially. It may be applied in the dry powder form or combined as follows, after thoroughly cleansing the parts involved:

℞.	*Acidi salicylici*	gr. ii	02
	Pulv. amyli	ʒii	8
	Zinci oxidi	ʒiv	15
	Adipis lanæ hydros. q. s. ad	℥i	30

M. Fiat unguentum. Sig.: To be applied locally night and morning.

Efforts should be made, in case of infants, to prevent scratching by tying the hands.

Chronic Prostatitis.

The treatment of chronic prostatitis outlined in The Journal, *Dec. 31, 1904*, will more exactly correspond with that of Dr. E. G. Ballenger, if carried out with the following details: The sounds should be placed in ice water before being placed in the urethra, for the purpose of solidifying the ointments made with oleum theobromate. Instead of the knee-chest position on the table, *Dr.* Ballenger recommends a semi-stooping position in which the patient rests his arms on the chair. The prescription preferred is as follows:

℞.	Argenti nitratis	gr. v-x	30-.65
	Olei *olivæ*	m. xv	1
	Lanolini	℥i	30

This should be introduced with an ointment carrier.

Medicolegal.

When Certificate of Death Is Competent Evidence.—The appellate term of the Supreme Court of New York says, in the case of Carmichael vs. John Hancock Mutual Life Insurance Co., that the certificate of the attending physician, when made a part of the proofs of death, is competent evidence on the trial as an admission against interest (Donnelly vs. Ins. Co., 43 Misc. Rep. 87; Hanna vs. Ins. Co., 150 N. Y. 526); and the cases which hold that such a certificate, when offered as such, without the characteristics of an admission by the plaintiff, may be excluded as privileged (Robinson vs. Supreme Commandery, 77 App. Div. 219; Davis vs. Supreme Lodge, 165 N. Y. 159), do not apply. Where the certificate has been delivered among the proofs of death, its character as proof is derived not from what the physician declared, but from what the plaintiff has admitted to be the fact, i. e., the cause of death, and the privilege which she might assert to exclude the evidence of the physician does not extend to evidence of what she has herself admitted.

Things to Which a Physician May Testify.—The Third Appellate Division of the Supreme Court of New York says, in the case of Becker vs. Metropolitan Life Insurance Co., where a policy was issued April 20, 1900, that the insurance company sought to show by a physician that on Oct. 30, 1899, he was called to attend the insured in his professional capacity; also whether he at that time did so attend him; also whether he had any record of the dates when he attended the insured in Norwich or elsewhere; also if he remembered how *long* the insured was confined to his house in October, 1899; also to give the dates between Oct. 30, 1899, and April 1, 1900, when he was called in to attend the insured, or when the insured called at his (the physician's) office to receive medical attendance from him. His answers to these inquiries were excluded, on the ground that they were prohibited by section 834 of the Code of Civil Procedure. This, the court holds, was error. It says that *neither of the questions* called for information that was in *violation of* such section, while such information was manifestly pertinent *to* the issue being tried, and would doubtless have much weight in controlling the jury's verdict

Promise for Town to Pay for Past Services.—The Supreme Court of Vermont says that in the case of Farmer vs. Town of Salisbury, brought by a physician, it appeared that, February 3, he was requested to visit a poor woman by a neighbor who promised to pay for that visit. The physician made the visit and informed the neighbor that the woman would require attendance for a long time. The neighbor declined to be further responsible, and by his advice the physician saw another neighbor, who tried to communicate by telephone with the overseer of the poor of the town, but, failing to do so, advised the physician to continue his visits, saying that he would see the overseer about the matter; but he did not see him until February 15, when he had an interview with him in the physician's behalf. The overseer then used language from which it was found that this neighbor understood, and had the right to understand, that the town would assume payment of the physician's charges, and that he so informed the physician. The trial court found that after the first visit the physician rendered his services in the expectation that the town would pay him, and, after this second neighbor's report to him, in reliance on such payment. The Supreme Court says that it was apparent that the overseer undertook to assume payment of the physician's entire bill, but there was no consideration for the promise to pay for the services rendered prior to February 15. They were not rendered on the overseer's promise to pay, and did not inure to the town's benefit. Therefore, the town was not liable for them, but was liable for the charges made after that date.

Communications to Physicians Not Privileged.—The Supreme Court of Rhode Island says that in the divorce case of Banigan vs. Banigan while a master in chancery was taking the deposition of a physician who had treated the defendant professionally, the witness objected to stating the disease for which he had treated the defendant. The master decided that the witness should testify. Thereon, the witness suggesting that the question as to whether he should be compelled to testify was one of much importance and that it should be decided by the court, the master suspended the proceeding, and filed a petition before Mr. Justice Dubois asking advice as to whether the witness was privileged to refuse to testify. The justice formally advised the master that the witness was not privileged to refuse to testify as requested by counsel for the petitioner, communications to physicians not being privileged in Rhode Island, and hence that the witness should be required to answer the question. The Supreme Court says that the petition by the master for instruction and advice above referred to was clearly within the jurisdiction of Mr. Justice Dubois, and, he having passed thereon, there was no authority in the Supreme Court either to reverse or to review his finding. It further says that there was obviously no reason for the justice who heard the matter in question to refer it to the larger quorum, since the uniform practice of this court from the earliest times has followed the rule of the common law in refusing to recognize a confidential communication to a physician as privileged, so as to protect the physician from divulging it when called on to do so as a witness in court.

Damages for Mental Anguish Without Physical Suffering.—The Supreme Court of North Carolina, in the case of Green vs. Western Union Telegraph Co., says that a significant fact is the growing tendency of judicial opinion to allow compensatory damages for mental suffering even when disconnected with any physical suffering. Of course, in cases merely of slander or libel, the court says, there could be no physical pain except as the reaction of mental suffering. The mere fact that a shock to the feelings which goes directly to the mind, without ever touching the body, may produce such reaction on the physical system as even to endanger life itself, is *per se* (by itself) the surest proof of the existence of actual suffering, and the strongest argument for the allowance of compensatory damages. If such suffering actually results directly from the wrongful act of the defendant, it would seem to make but little difference what were the collateral circumstances. Again, the court says that when we remember that this doctrine of mental anguish in telegraph cases is of recent origin, having theretofore been deemed contrary to the principles of the common law, and has made constant progress in opposition to the preconceived ideas of courts and jurists, it seems that it must possess much inherent strength and merit. This is especially evident from the action of certain courts, some of them of the highest reputation, which, while denying the doctrine in telegraph cases that damages for mental suffering may be recovered in the absence of physical pain or injury, allow it in cases of a kindred nature, such, for instance, as insulting or humiliating a passenger. An examination as to the present status of the doctrine in the different states, so far as ascertainable, shows it adopted in telegraph cases in Texas, Tennessee, Alabama, Kentucky, Iowa, Louisiana, South Carolina, Nevada, Washington (indirectly). The doctrine is denied, as shown by the most recent cases in Florida, Georgia, Illinois, Indiana, Kansas, Minnesota, Mississippi, Ohio, West Virginia, Wisconsin, Virginia. In this case a statute was passed on the subject, which apparently failed of its purpose. In the following states there have apparently been no decisions in telegraph cases on the subject: Arizona, California, Colorado, Connecticut, Delaware, Idaho, Maine, Maryland, Massachusetts, Michigan, Montana, Nebraska, New Hampshire, New Jersey, New York, North Dakota, Oregon, Pennsylvania, Rhode Island, South Dakota, Utah, Vermont, and Wyoming.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

January 14.

1 **The Foundations and Aims of Modern Pediatrics.* Theodore von Escherich, Vienna, Austria.
2 [illegible] Ray and Surgical Treatment of [illegible] R. Bullitt, Louisville, Ky.
3 [illegible] of Hypertension. Henry Wireman [illegible]
4 *Intussusception of the Appendix Vermiformis. George Emerson Brewer, New York.
5 *Lithemia: Its Diagnosis and Local Treatment. F. M. Johnson, Boston.
6 Three Interesting Cases: *Gastroptosis and Dilation; Chronic Tenosynovitis; Thoracic Abdominal Aneurism.* G. Childs MacDonald, San Francisco.

1. **Modern Pediatrics.**—Escherich reviews the various steps taken by pediatrics in its development into a science and which have considerably extended and clarified the study of pediatrics. Modern pediatrics exhibits a scientific structure including all disturbances of the life processes, arranged according to scientific principles, and in its completeness not reached by any other specialty in medicine. Only a small number of diseases can be considered peculiar to childhood, because they are caused by events which can not occur in the life of adults, such as the change from intrauterine to extrauterine life, and growth and development. The key to the understanding of the special pathology of the infantile organism is to be found in the study of developmental processes. Between the growing organism of the child and that of the completely developed adult great differences exist in the reaction called forth by the diseased process, the variations, which change constantly in the course of childhood. The author also considers the threefold division of childhood accepted by Vierordt, which he accepts as the most scientific as well as practical.

4. **Intussusception of the Appendix.**—Brewer cites the case of a woman, aged 22, suffering from symptoms of acute appendicitis. The abdomen was opened, and a prolonged search made for the appendix, which proved futile. Five months later the patient again presented herself, complaining of constant pain and tenderness in the right iliac fossa. The abdomen was again opened, the ileo-cecal region was dissected free from a mass of adhesions and thoroughly inspected. No trace of the appendix was found, but on palpating the cecum an elongated oval body was felt within its lumen. The intestine was opened by a longitudinal incision, and the inverted appendix was found projecting into the cecum. The patient

made a satisfactory convalescence and is entirely relieved of all symptoms. Brewer suggests that the condition was a congenital one and that the acute attack was due primarily to the inflammation of the cecum which resulted in a stricture with secondary involvement of the appendix. Or, that as a result of a catarrhal appendicitis, with or without the presence of a foreign body, the muscular efforts of the appendix to rid itself of its contents became so violent as to produce an intussusception in the same manner as the lesion is produced in other portions of the intestine.

5. **Lithemia.**—Johnson emphasizes the great value in lithemia of the microscopic findings in the urinary sediment, not only because of their diagnostic importance, but also because they serve accurately to indicate certain essential lines of treatment. He says that if catarrhal inflammation of the kidney is present and the bladder is likewise involved, thorough washing out of the bladder and lavage of the kidneys are of great value. When carefully done the procedure is harmless. The invasion of an ascending inflammatory process is completely stopped and accumulating concretions are washed away. The treatment is discussed in full.

Medical Record, New York.

January 14.

7 *Diseases of the Isthmian Canal Zone. Richard L. Sutton, U. S. A.
8 Value of Publicity Regarding Tuberculosis. Denslow Lewis, Chicago.
9 Sudden Death, [illegible] Embolism Following Surgical Intervention. [illegible] Chicago.
10 Treatment of [illegible] James W. Hunter, Norfolk, Va.
11 Infections of the Gall Bladder. Thomas W. Harvey, Orange, N. J.
12 *Pneumonia in High Altitudes. Summary of 101 Cases of Lobar Pneumonia Treated at the American Hospital, Mexico City, from 1890 to 1904. Albert R. Goodman, Mexico City.

7. **Diseases of Isthmian Canal Zone.**—Sutton reviews the diseases to be encountered in this particular territory, and the conditions which must be met by medical men. He says that the practitioner who expects to find a case of "yellow jack" or black water fever in every native clinic he conducts, will be greatly disappointed. These diseases are present at times, but are encountered much more seldom than the average reader would be led to imagine. Malaria is probably more frequently seen than any other affection among the natives. Long-continued residence and many attacks of malaria have combined to render the older inhabitants partly or wholly immune to the infection. The disease is encountered very frequently, however, among children, from earliest infancy to adolescence. The estivo-autumnal type is the most common. Often the symptoms seen are not directly indicative of malaria at all. The onset may be very atypical. Mixed tertian and estivo-autumnal fever is seen rarely, and no case of quartan infection has been discovered. Patients suffering from advanced degrees of malarial cachexia are often met with. Dengue is the disease which most frequently attacks the new arrival in the Isthmus, and even the more acclimated natives do not wholly escape it. The disease is extremely contagious, and many persons in the same place are usually attacked at the same time. Beri-beri, seen most frequently in the wet lowlands and marshy districts, thrives in the Isthmus, especially affecting the Chinese contingent. Both the dropsical and paraplegic forms are seen, often the two are associated. Infection with intestinal parasites is the rule. The eggs of half a dozen different species can be found in nearly every specimen examined. The parasites found are the *oxyuris vermicularis, tricocephalus trichiuris, ascaris canis* and *ascaris lumbricoides, strongyloides intestinalis,* and *uncinaria duodenalis.* One of the most troublesome insects on the Isthmus is the "jigger," the *culex penetrans.* Snakes, centipedes and spiders are numerous, but the danger from them is not great. Heat exhaustion and sunstroke occur more often among the Americans than any other class. Dysentery is still much in evidence, especialy among the natives. *The disease is of both* types, the acute specific, due to Shiga's bacillus, and the amebic, with the former predominating. Acute and chronic articular rheumatism also occur, and myalgia, especially of the lumbar muscles, is frequently encountered, malarial infection probably being the causative agent in many cases and dengue in others. Smallpox makes occasional inroads. Yellow fever is not at present epidemic and sporadic cases are seldom seen. Sutton says that the Isthmus is now in better condition, from a hygienic standpoint, than it has ever been, and, taking even the peculiar character of the climate into consideration, the health of the inhabitants will soon compare favorably with that of the residents in any extreme southern country.

12. **Pneumonia in High Altitudes.**—Goodman gives a summary of 101 cases of lobar pneumonia treated at the American Hospital in Mexico City during the past fifteen years. Of this number, 91 were males and 10 were females. The greatest number of cases, 79, occurred during the first six months, only 22 cases occurring in the second half of the year. Pneumonia is frequent before the rainy season and decreases during the rains and directly afterward. The average mortality for all cases during this time was 39.8 per cent. Deducting 4 cases in which death occurred within twenty-four hours after entering the hospital, the mortality is 37.1 per cent. Of cases treated since 1898 (since when more accurate records have been kept)—68 in all—the mortality was 50.1 per cent.; of these 4 died within 24 hours after admission, leaving the mortality of the remaining 57 cases, 47.4. The average of these 4 mortality percentages is 43.5, which in Goodman's opinion represents fairly accurately the actual mortality of pneumonia as existing in the hospital.

13 *Care of Puerperæ. James D. Voorhees, New York.
14 *Trauma and Chronic Compression of the Epigastrium as Etiologic Factors of Gastric Ulcers. William Ackermann, Milwaukee.
15 Nervous Symptoms Accompanying Pernicious Anemia. Roy M. Van Wart, New Orleans.
16 *Prostatectomy in Emergency Cases. John F. Erdmann, New York.
17 Observations on the Blood Pressure in Disease. Roger S Morris and Charles W. Edmunds. Ann Arbor, Mich.

13. **Care of Puerperae.**—Voorhees advises continued asepsis after delivery. For the first two or three days he places a piece of gauze wet with a 1 to 10,000 bichlorid solution over the vulva beneath the sterile vulva pad. Early vaginal examination and douching he condemns. After from ten to twelve days hot douches undoubtedly help the involution of the uterus. In some cases where the uterus continues to relax immediately after delivery, he often gives an intrauterine douche of acetic acid with good result. Voorhees says he often doubts the efficacy of the abdominal binder, although for the first two or three days it does keep down the gas and supports the abdominal walls. And in short-waisted women who have carried the child high and well out in front, it prevents an anterior relaxation of the abdominal walls. But for women who carry the child low and well backward, they are more or less unnecessary. Consequently, if such cases are bothered by the binder after the third to fifth day, he allows it to be discarded. To insure as complete involution as possible, Voorhees advises that on the second day the patient should be turned first on one side and then on the other; on the fifth day she should commence to lie on her abdomen for shorter or longer periods and be encouraged to sleep in this position, if possible. This change in posture favors the escape of the lochia and allows the uterine ligaments to contract, so favoring normal anteflexion. He advises keeping the patient in bed at least two weeks and longer if any signs of subinvolution persist. If involution is delayed, hot vaginal douches, boroglycerid tampons, ergot, quinin and strychnin are of service. The routine vaginal examination should be made before any case is discharged to determine the possible existence of erosions, inflammations, displacements, etc.

14. **Etiologic Factors of Gastric Ulcer.**—*Ackermann* discusses the influence of traumatism and epigastric compression, particularly long continued, in the causation of gastric ulcer. He says that, taking into consideration the fact that men, owing to their occupation, are more liable to epigastric compression than women, it is plain why ulcers occur more frequently in

men than in women during the latter years of life. And that in all probability many cases of gastric dilation thought to be due to perigastritis really owe their existence to cicatrices following traumatic ulcers. Sixteen cases are cited in which constant pressure on the epigastrium was followed by gastric ulcer. Both the occupation of the patient and the situation of the ulcers seemed to substantiate the author's view of the importance of compression, the ulcers usually being found near the pylorus, this part of the stomach being more exposed to pressure.

16. **Prostatectomy in Emergency Cases.**—Erdmann calls attention to the advantages of doing a prostatectomy in every instance possible, when the prostate is in part the cause of obstruction, in cases coming under the head of emergency drainage of the bladder. He cites records of eight cases that belong distinctly to this class in which relatively six different emergency indications are dealt with. The cases were as follows: 1. Impassable urethra due to stricture with rupture and gangrene of the entire scrotum and perineum. 2. Retrograde hemorrhage, bladder being full of clots and bloody urine, with malignancy of prostate. 3. False passage; retrograde hemorrhage; suprapubic aspiration, with infiltration of abdominal wall extending to the thorax and to the gluteal regions. 4. Acute obstruction due to eposure to cold and wet, inability to catheterize; trauma of the urethra. 5. Trauma of the urethra; catheterization for several days. retrograde hemorrhage, etc. 6. Deep stricture of the urethra; obstruction; catheterization cystitis with absorption. Erdmann is of the opinion that drainage by prostatectomy in these cases is the only method of procedure and that the perineal route is the one to be selected in practically every instance. Cases 1 and 3 died, but not because of anything in connection with the operation. Erdmann recommends emergency operative procedure because (a) only a few minutes more are required to remove the gland, the hemorrhage as a rule is not excessive, and the operative procedure itself does not increase the shock to any degree. (b) The removal of the prostate gives proper exit to the urinary outflow and admits of easy drainage. (c) Washing the bladder is much facilitated. The perineal route is recommended because (a) the opening is practically at the lowest point of the bladder and complicated devices for drainage, such as are necessary in suprapubic sections, are not required. (b) The old, being irritable and feeble and requiring to be moved frequently, the drainage in the suprapubic method is constantly interfered with, while in the perineal method it is controlled. (c) The after-soiling, when the tube is removed, is slight, and easily controlled in the perineal method as compared with the suprapubic. (d) Bladder irrigations are more readily done with less soiling of the bed, etc.

18 The Present Status of Railway Emergency Work. U. F. Martin, New York.
19 *A Clinical Study of Myoidema with Especial Reference to Its Occurrence in Pulmonary Tuberculosis. Henry L. Shively, New York.
20. Radium; a Review of the Literature. Fred G. Hodson, Atlanta, Ga.
21 Differentiation in the Diagnosis of Non-deforming Club-foot. John Joseph Nutt, New York.
22 *Tic Douloureux and Other Neuralgias from Intranasal and Accessory Sinus Pressures. Sargent F. Snow, Syracuse, N. Y.
23 Biliary Colic Without Gallstones. John G. Sheldon, Telluride, Colo.
24 The Proper Scope of Scientific (So-called Expert Testimony in Trials Involving Pharmacologic Questions (concluded). Solomon Solis-Cohen, Philadelphia.

19. **Myoidema in Tuberculosis.**—Shively has found this symptom present not only in tuberculosis pulmonalis, but also in typhoid, lobar pneumonia, acute and chronic bronchitis. carcinoma of the breast, aneurism of the arch of the aorta. and in secondary syphilis, and he has also observed it in perfectly normal individuals. In a series of 750 consecutive cases of tuberculosis of the lungs, myoidema was present in 703. Of this number, 196 were incipient. 475 moderately advanced and 79 advanced cases. In the incipient cases the fibrillary and nodular variety of myoidema could be obtained in 135; the nodular alone, in 19; the fibrillary alone, in 24, and neither form in 18. In the moderately advanced cases both kinds were present in 379; the nodular alone, in 30; the fibrillary alone, in 37, and neither form, in 29 cases. In the advanced cases both varieties were obtained in 74; the nodular in 4 cases, and the fibrillary in 1 case. It would seem that a phenomenon found in such widely different conditions could have but little diagnostic significance in any one of them. Yet, it is apparent that it is present in the great majority of all cases of tuberculosis of the lungs, and that it is usually obtained even in the incipient stages of the disease. Therefore, it is not without some importance as an addition to the syndrome of signs and symptoms which makes the early diagnosis less difficult. Myoidema, says Shively, is one of the indications of departure from health which should receive some consideration.

22. **Pressure Neuralgias.**—Snow believes that many cases of tic douloureux arise from intranasal and sinus pressure, and that 80 per cent. would be a modest estimate. The intense aggravated forms of headaches characterized by convulsions, rigidity of muscles, etc., that he has observed have been in females where a combination of both marked nasal and uterine factors existed. He advises careful and thorough inspection of the intranasal and accessory sinuses in such cases.

28 Consideration of Autointoxication and Autoinfection as a Cause of Various Mental Disorders (concluded). L. Vernon Briggs, Boston.

25. **Work as a Remedy in Neurasthenia.**—Hall protests against the almost universal application of rest in the treatment of neurasthenia and allied conditions. A study of the etiology of this rather indefinite disease has led him to some conclusions as to treatment that are a little at variance with the usually accepted ideas. Hall believes that some means must be devised whereby the neurasthenic or anyone who, for reasons of mental and nervous hygiene. might need to change his occupation and habits of life, could do so without the shock or failure which the usual desultory and spasmodic attempts at such an action imply. The great need seems to be to lift the neurasthenic out of his tangle of nervous symptoms, not by substituting another abnormality in the shape of unduly prolonged rest, but by bringing about, by a gradual process, the conditions of the normal life, a life of pleasant and progressive occupation, as different as possible from the previous life and resulting in self-forgetfulness. Manual work is best, for it is objective and wholesome, and trains to accuracy and precision of movement. In order to test the soundness of these preconceptions, Hall established a practical shop for the manufacture of pottery and for the production of a variety of fabrics by means of hand weaving. A competent teacher was secured, and she, with a few assistants, proceeded to make the shop practical and effective from a mechanical and artistic point of view. The shop was popular at once and had a very encouraging effect on the early patients. Basket-making has recently been introduced and is proving very useful. The work of the patients has been surprisingly good when judged by exacting standards. Having established this shop and made it practicable for those mildly affected, the next step was to attract and hold a confirmed neurasthenic and to enable them to escape the usual consequences of exertion. In the lighter cases there was no difficulty. The surroundings were so novel and the work so attractive that before they realized it themselves, these patients were hard at work. After eliminating as far as possible such evident sources of irritation as eyestrain, the problem seemed that of diminishing the prohibitive or anticipatory fatigue symptom. To do this Hall begins a treatment by a short period of rest in bed, perhaps a few days, perhaps a week, under the usual rest-cure conditions. Then, without any warning whatever, the patient

is required to do something. A very gradually progressive program is written out each day and intrusted to the nurse, the patient having no knowledge of what is expected of him. This device has proved exceedingly satisfactory. The progression leads to the shop and it depends on the work there, the actual living of a rational life, to fix and render permanent the improvement. The hours of rest are gradually made shorter and the hours of work longer until the day is full of interest and self-forgetfulness and the need of prolonged rest is lost. After a few weeks of work, when the inertia of months or years has been cast aside, it is remarkable to observe the change in facial expression, in precision and skill of movement, and in the whole morale of the patient. To encourage a feeling of independence, it has been decided that when a patient can turn out work of value the product may be sold through the agency of the shop and the proceeds credited to the maker. In order to test more thoroughly the efficiency of treatment by work, little or no use has been made of special baths, massage and electricity. The one great end to be obtained is self-forgetfulness and a pride and satisfaction in work and in life. While the agents mentioned are of value and are sometimes necessary, yet they constantly call the patient's attention to himself and to his symptoms. Hall hopes that the treatment by work will not only sidetrack the neurasthenic state, but will substitute a simple, but positive efficiency which will reorganize the life of the individual on better lines and which will do it substantially and speedily without undue mental strain on the part of the physician, nurse or patient.

26. **Improved End-to-End Intestinal Anastomosis.**—According to Gould, the only original feature of his technic is the method of beginning the first layer of continuous sutures. It is customary to start at the free edge of the bowel and sew toward the mesentery. This makes it necessary to work in a pocket while crossing the mesenteric border. For this reason it is preferable to place the first guides in such a manner that the mesenteric border will be first developed, and, when this has been sewed across, the rest is plain sailing. The size of the catgut is important. No. 0 chromic gut is amply strong and threads easily in a No. C milliner's needle, which is twice or three times the size of the usual needle employed. No. I Pagenstecher's celloidin thread and No. 0 chromic gut thread so easily that it can be done without any delay during the operation. The anastomosis is made with three separate stitches: 1. The mattress mesenteric stitch (Maunsell, Connell). 2. Continuous suture of all coats. 3. Interrupted or continuous seromuscular stitch (Cushing or Lembert). After the usual clearing of the lumen of the gut, short-jawed clamps are applied, leaving a margin of about three inches on either side of the area to be cut out. Handkerchief gauze is wrapped around the intestines beneath the clamps to isolate the field of operation. The resection is done by means of scalpel and scissors. Hemorrhage from the mesenteric vessels is checked at once. The placing of the Maunsell mesenteric mattress stitch forms the starting point of the anastomosis. This should enter and leave the bowel at least an eighth of an inch from the cut edge, but should penetrate the mesenteric space and peritoneum farther forward. The mesenteric third of the bowel circumference is rather inaccessible, and, to bring this portion forward, guide stitches are introduced with the ends left inside. On tightening the guides, the remaining circumference of the bowels falls away and the inverted edges are freely exposed at their mesenteric attachments. To control hemorrhage and to bring the cut edges together, a continuous chromic catgut stitch is used, size preferably No. 0. This stitch starts near one of the guides and is knotted on the outside where a long end is left to tie to the last stitch after it has completely approximated the circumference of the cut edges. The continuous through-and-through stitch passes across from one guide to the other. When the second guide has been reached, a third guide is introduced half way between the first two, on the free edge of the bowel opposite the mesenteric attachment. The ends of this guide are left outside. Traction on this and on the lower guides will make easy the completion of the continuous suture. The last stitch is knotted to the long end left on the first knot and the guide is removed. The continuity of the chromic stitch must be broken at points an inch or so apart. This makes it difficult to narrow the lumen by drawing the catgut into a purse-string and also gives greater security to the joint. The most important step is the seromuscular stitch. Both continuous and interrupted sutures are employed for this purpose, but the Lembert interrupted is the more reliable, on the whole. The first interrupted seromuscular stitch is placed opposite the mesenteric border, and this is followed by a stitch at the mesenteric edge on either side. The ends of these three stitches are left long, as they make excellent guides for the remaining stitches, which are introduced in the usual way. The mesentery is finally brought together by a few interrupted catgut stitches.

44 Case of Right-sided Infantile Hemiplegia, with a Description of the Pathologic Changes Found in the Brain and the Spinal Cord. Robert Reuling, Baltimore.

37. **Pathology of Fat and Fatty Degeneration.**—Christian has found that visually demonstrable fat is present normally in very many cells of the body, while extracted fat occurs in practically all of the tissues. Under abnormal conditions the visually demonstrable fat appears in the cells in increased amount and is always an index of cell injury. With regard to fatty infiltration and fatty degeneration, he says that fatty infiltration is the physiologic appearance of fat in normal cells, and that fatty degeneration is the appearance of fat in injured cells; the fat is an index rather than the direct result of cell degeneration. However, in both conditions the origin of the fat is probably the same, coming from without the cell by transport from fat depots elsewhere, but it may arise within the cell from fat related bodies, not from proteid.

41. **Tuberculin in Orthopedic Surgery.**—Baer and Kennard detail the results they have obtained from the use of tuberculin in orthopedic surgery. Forty private patients were injected. The cases were selected almost invariably in order to clear up the diagnosis. Twenty-five gave a positive and 15 a negative reaction. Of the former, 6 were subsequently operated on and all proved to be tubeculous. In 18 of the remaining 19 cases the diagnosis was verified by the subsequent history and the response to treatment. The remaining case is a recent one and therefore not available. Of the 15 patients who did not react, one was operated on and no evidence of tuberculosis was found; of the other 14, 8 have recovered under non-tuberculous treatment; the remaining 6 are improved and all suspicion of tuberculosis has been removed. Radiographs were taken of 15 of the 25 cases which reacted to tuberculin. Six

showed a focus, in 5 the disease was suspected only, and 4 showed no lesion. The authors consider tuberculin the best and most reliable diagnostic agent for incipient tuberculosis of bones and joints. Its proper administration is attended by no permanent, harmful effects. The dosage is variable, but it is rarely necessary to give more than six milligrams. The local signs following the use of tuberculin they consider of equal, if not greater, importance than the general reaction in bone and joint tuberculosis. Previous to the injection of tuberculin, the local seat of disease should be examined carefully for all signs of the suspected trouble. In response to the tuberculin, if tuberculosis be present, all the local signs of the disease will be distinctly increased; that is, motion will be more limited, the deformity will be greater; tendinous and muscle spasm will be exaggerated, and local temperature may be increased. Tuberculosis practically always reacts to tuberculin. Although radiography is of value in the diagnosis of these conditions, the use of tuberculin permits of an earlier and more positive diagnosis than the x-ray.

St. Paul Medical Journal.

January.

45 *A Method of Total Excision of the Ureter, with a Few Incidental Remarks on Kideny Tuberculosis. Arnold Schwyzer, St. Paul.
46 *The Control of Smallpox. H. M. Bracken, Minneapolis.

45. **Total Excision of the Ureter.**—The value of Schwyzer's method lies in the reduced amount of disturbance of the tissues, in the reduced size of the abdominal incision, and in the greater feasibility of a complete excision of the ureter, as compared with other methods. In cases of firm addhesions of the ureter to the surrounding tissues, or of advanced tuberculous periureteritis, it can not be employed. To better illustrate the method, Schwyzer mentions the case in which it was used. The patient, a woman, aged 23 years, was found to be suffering from a right-sided tuberculosis of kidney and ureter, with secondary infection of the bladder, and with the left kidney not beyond suspicion. Inasmuch as something had to be done, he decided on a preliminary exposure and exploration of the kidney. An incision was made four inches long, parallel to the costal border and an inch below the twelfth rib, beginning just outside the sacrolumbalis muscle. The fat capsule of the kidney was very dense, so that it was with difficulty that the kidney was separated from it. The kidney was rather large, and the fibrous capsule was ragged. A small incision was made into the convex border of the kidney. Through this a very soft silver probe was passed well down into the ureter, nothing but blood escaping from the wound. A large, soft-rubber catheter was passed through this opening and down about three inches into the ureter. It was left there for drainage. The abdominal walls were closed up to one inch for drainage. A week after the nephrotomy, he excised the kidney and ureter. With the patient in the lithotomy position, an incision, a little over one inch long, was made into the right vaginal vault over the region of the ureter. The ureter was somewhat freed, and a blunt hook was introduced over it. It was then dissected out of the bladder wall. Its end was caught and the bladder wall sutured with catgut. A string was tied to the free end of the ureter. The stitches were removed from the former lumbar incision, which was extended to five and a half inches in length, the anterior end of the incision being two cm. and seven cm. above the anterior superior spine. The kidney was freed and the ureter dissected out with the fingers for a considerable distance. The renal vessels were tied and the kidney cut off from them. The kidney was now outside of the wound and free, except from its attachment to the ureter. Two fingers of the left hand were next inserted down along the ureter, while two fingers of the right hand worked themselves through the incision in the right vaginal vault, also following the ureter. The fingers of the two hands worked about the ureter until they met. They were helped in their freeing action by the assistants pulling on the lower end of the ureter and alternately on the kidney. A small drainage tube was left in the vaginal opening. A drainage tube with gauze was placed in the upper wound, and the lumbar incision was closed, except about the drain. The patient is having a troublesome convalescence. Where the distance from the nephrectomy incision to the incision in the vaginal vault is much too great for the fingers of the operator, a small incision, just allowing two fingers to pass, could be made above Poupart's ligament, and the ureter, held in tension by pulling, can easily be reached and found extraperitoneally over the border of the iliac vessels. From there the fingers of the two hands will reach each other with ease and work bimanually. In order to use the same method in male patients, a perineal section would be necessitated, a much more complicated operation than the one in the female.

46. **Control of Smallpox.**—Bracken believes that statistics the world over have demonstrated fully that the proper enforcement of vaccination will prevent the occurrence of smallpox. And that it has also been demonstrated, that it is impossible to control smallpox by any known method of quarantine. Recognizing these facts as true, efforts to control this disease should be based on vaccination rather than on quarantine. Without vaccination there is no reason why smallpox in time should not again become as great a scourge throughout the world as it was in the prevaccination era. Compulsory vaccination laws are important. These should be demanded by the laity. Physicians should use their influence in favor of vaccination, but they should not place themselves in a false light by trying to force legislation demanding compulsory vaccination laws. Such laws should be demanded by the people as a means of self protection. However, if the people choose to follow the leadership of faddists against vaccination, rather than the scientific teaching and actual demonstrations in favor of vaccination, then on the people should rest the responsibility for the consequences resulting from failure to protect against smallpox by means of thorough vaccination. Bracken states emphatically that quarantine is either evidence of a lack of scientific knowledge as to the proper means to be employed in the control of a communicable disease, or inability to apply such knowledge. Therefore, the attempt to control smallpox by means of quarantine should be abandoned, for it is unscientific, impracticable, expensive and an absolute failure. The present methods of quarantine for smallpox should not be discontinued suddenly, but after a sufficient time has elapsed to permit of the creation of compulsory vaccination laws.

50. **Combined Treatment in Eye Disease.**—Burnham considers the treatment of various diseases of the eye by a combined method, that is, the internal administration of mercury and potassium iodid, associated with the hypodermic injection of pilocarpin, which he has been using for fifteen years. He finds that it stimulates the nerve centers to a remarkable degree, and through them the ordinary physiologic processes of the affected part or parts especially are aroused to an activity far in excess of the normal, and thus the diseased condition is acted upon and removed. Moreover, this hyperactivity can be regulated and sustained for years, if necessary, by the manner in which the combined treatment is administered. The method has proved unusually successful in the treatment of cases of very severe cyclo-irido-keratitis, failing vision in a rheumatic, acquired syphilitic cyclo-iriditis, hypopyon keratoiritis of the worst type, albuminuric neuroretinitis, cerebral syphilis, choroido-retinitis, and corneal nebula, specific or nonspecific.

53. **Erythema Infectiosum.**—Shaw calls attention to a disease which he says has been described independently by several well-known pediatrists and which, in his opinion, has clinical features distinct enough to justify its classification with the acute exanthemata. The priority of recognition as a separate disease entity belongs to Escherich. Erythema infectiosum is a feebly contagious disease, occurring chiefly in children between the ages of 4 and 12 years, with very slight subjective symptoms, and characterized by a maculopapular, rose-red rash, pronounced on the cheeks, legs, and outer surface of the arms. The specific agent is unknown. The disease occurs in epidemics and often follows an outbreak of measles or rötheln. Both sexes are equally affected. It occurs most frequently in the spring and summer months. The period of incubation varies from six to fourteen days. The disease may be ushered in by a slight feeling of malaise, weakness and sore throat, but in the majority of cases the first symptom noticed is the eruption. This is the most important and often the only symptom. It appears invariably on the external skin, usually first on the face, chiefly the cheeks. The skin is hot to the touch, is swollen, but is not sensitive; nor does it itch. The whole appearance is suggestive of erysipelas. The eruption is confluent over the cheeks, and the edges are well defined. slightly raised and distinct from the normal skin. The area of confluent eruption is rather sharply limited in front by the nasolabial folds and above by the temples. Laterally, it extends to the angles of the jaws. Discrete spots are often seen on the forehead and chin. The rash fades from the face after four or five days. On about the second day the eruption makes its appearance on the body, where it is most marked on the outer surface of the legs and arms. The trunk is involved to a much less degree, and may be almost free. The hands and feet are the last portions of the body to be affected. An evanescence is often observed which is perhaps peculiar to the disease. The eruption is not followed by desquamation. No hemorrhage results on pinching the skin. The lymph glands are not enlarged. The subjective symptoms are conspicuous by their absence. Measles can be excluded by the absence of involvement of the mucous membranes, of all constitutional symptoms and of Koplik's spots. In rötheln the rash spreads rapidly over the entire body and is of a different character from that seen in erythema infectiosum. There are also constitutional symptoms.

59. **Primary Sarcoma of Bladder.**—Three cases of this kind are reported by Wilder: 1, a round-celled sarcoma in a man, aged 48 years; 2, a fibro-sarcoma in a man, aged 53 years; 3, a mixed-celled (spindle and round) sarcoma in a man, aged 62 years. While sarcoma of the bladder is most common after middle life and during childhood, it *may* occur at any age. Of 50 cases studied, 26 occurred after the age of 40, and 14 cases under the age of 10. It is more common in males than in females. The most constant symptom is hematuria. Next in order are the symptoms of cystitis and vesical irritation—strangury, frequent and difficult micturition, small stream, retention, and purulent urine. Emaciation consecutive to the growth is present in advanced cases only. A calculus may or may not be present. As a rule, the disease is more rapidly fatal in children than in adults. The most common location of the tumor is at the base of the bladder in the vicinity of the urethral orifice. It is usually sessile, with a broad base, soft and friable, more or less lobulated, and in some cases has a cauliflower or villous appearance. Metastases, as compared with sarcoma of other parts of the body, seem rare, except in quite advanced cases. At the present time, the only hope for cure appears to lie in the early detection of the neoplasm by means of the cystoscope, or by exploratory incision, and its complete removal at this stage of the disease.

60. **Arrest of Growth and Absorption of Epithelioma.**—Randolph reports a case of endothelioma appearing on the posterior aspect of the left forearm which started in the subcutaneous connective tissue, grew steadily and painlessly for six months, and then, for some unknown reason, became arrested. Necrosis or atrophy of the cells of the tumor took place, and later this inactive tissue began to act as an irritant, exciting a productive inflammatory process which endeavored to remove the foreign mass. There was active hyperplasia, with a very marked round-celled infiltration. Very charcteristic was the development of numerous giant cells. Their peculiar arrangement seemed to show that the function of these cells is an absorptive or phagocytic one.

7 Anthropometric Investigation of Hospital Patients (concluded). F. C. Shrubsall.

2. Tubal Pregnancy of Years' Duration.—Fenwick's patient, aged 45, had a large abdominal tumor, fecal urine, pneumaturia, hectic temperature of long duration, and great emaciation and cachexia. On cystoscopy the bladder was found comparatively healthy, but was bulging forward, and under the prominence was a fistulous opening. He made a diagnosis of suppurating ovarian dermoid and cut into the tumor above the pubes. It was evidently intraperitoneal, but adherent to the abdominal wall so that the peritoneal cavity was not opened. Pus, feces and gas escaped in large quantities. After thorough irrigation a bare fetal femur appeared at the incision and then a humerus. A mascerated fetus was felt lying in a puddle of feces, pus and liquid rottenness. Parts of the skull bones were adherent to the walls of the sac and had to be peeled off with some force. The bowels were adherent to the sac and greatly softened. Fenwick packed the cavity of the sac, but the patient died in a few hours. Shortly before her death the patient stated that eight years ago she became

pregnant, and when she was decidedly big she made arrangements for her confinement. The various symptoms of pregnancy, however, gradually disappeared and her abdominal swelling subsided slightly, but for the last seven years she had a large lump in the right side. Three months ago she received a severe blow on this lump, and two days later she had great pain which persisted, causing her to seek medical aid. Postmortem examination showed a left tubal pregnancy which had suppurated, become adherent in every direction and perforated into the bladder and the sigmoid bowel. The sac which had contained the fetus could not be dissected away from the hollow viscera which surrounded it. The bones of the fetus were examined and found to be about the fifth month.

5. **Bacteriology of Enlarged Prostate.**—Dudgeon and Wallace made careful examinations of seven enlarged prostates, with a view to ascertaining whether the condition is the result of infection or not. In 5 of the 7 cases unmistakable signs of infection were found, consisting of pure cultures of the staphylococcus albus in 3 cases and bacillus coli communis in 2. In one of the latter diplococci were also found present. In some instances the infecting organisms were the same as those found in the urine. The authors conclude that, to a certain extent, the results obtained support the view that the initial lesion in prostatic enlargement may, in certain cases, be a septic infection from the bladder.

9 *Treatment of Streptococcic Puerperal Fever by Antitoxic Serum. Alexander G. R. Foulerton.
10 *Case of Streptococcic Puerperal Infection Treated with a Special Puerperal Antistreptococcic Serum; Recovery. Thomas Rose.
11 *Administration of Antistreptococcic Serum. J. W. Thomson Walker.

9. **Antitoxic Serum in Streptococcic Puerperal Fever.**—Foulerton has found that the relative importance of streptococci in puerperal infections is even more marked than a consideration of previous bacteriologic researches on the subject appears to indicate. He and his associate, Dr. Bonney, have found streptococci of one sort or another in the uterus in 46.3 per cent. of a series of 54 cases examined, and in these cases the organisms were found under conditions which indicated that they were the primary cause of the fever. Excluding the less severe cases of fever occurring after childbirth, and considering only those which either ended in death or were clinically of a distinctly serious nature, they found streptococci present as the presumable cause of disease in 62.5 per cent. Up to the present time they have dealt with 25 stains of streptococci isolated from the same number of cases of puerperal fever, and they have satisfied themselves that among these 25 strains there is more than one distinct species. An antistreptococcus serum was prepared in the ordinary way, the horse having been vaccinated with 5 of the strains. As yet this serum has been used in only a few cases, but among them there have been 2 cases of recovery after extremely severe forms of streptococcus infection. Apart from the failure of serum treatment in puerperal fever arising from uncertainty as to the particular strain of streptococcus which is present, the question of the dosage of the serum employed is of considerable importance. Regarding the matter entirely from the clinical point of view, it would seem that the action of an antistreptococcic serum is purely antitoxic and that the infecting bacteria remain unaffected by the serum and continue to elaborate their specific toxins. In order to neutralize these toxins which are being continuously thrown into the patient's circulation, repeated doses of the serum must be given until the infection comes to a natural termination. Foulerton says it is advisable to commence treatment with an injection of at least 20 c.c., and one must be prepared to repeat this dose, if necessary, at least every twenty-four hours. If no improvement follows two doses of 20 c.c. each, administered within twelve hours, it is useless to persist in administering it. Another brand of serum should at once be tried. Large doses are necessary for any success.

10. **Ibid.**—Rose reports a case of an extremely severe type of streptococcic infection in which there seemed to be no doubt that ultimately recovery was due to the action of an antistreptococcic serum.

11. **Administration of Antistreptococcic Serum.**—Walker finds that the injection of antistreptococcic serum in cases of pure streptococcal infection has been followed by strikingly beneficial results. The variability in the results of the serum unquestionably has been due to the selective activity displayed by the antitoxin of each variety of streptococcus, or to the serum being used too late or having lost its activity from staleness. More uniform results are likely to be obtained from the present compound antistreptococcic serum than from the earlier forms, from the prompt injection of serum at the commencement instead of near the close of a severe infection, and from the use only of serum which has been recently prepared. The administration of the serum for some days after the general symptoms have disappeared in order to avoid a recrudescence. The question of dosage must be judged by the nature of each case and the effect obtained by the injection, but it is important to know that large doses spread over several days have been used without ill effect. The most rational method would seem to be that of a large injection (from 20 to 25 c.c.) on the first occasion, followed by smaller doses as the case may require.

Indian Medical Gazette, Calcutta.

December.

12 *Further Notes on the Treatment of Leprosy by Injections of Leprolin. E. R. Rost, Rangoon.
13 A Short Account of the Various Trypanosomata. A. Lingard.

12. **Leprolin in Leprosy.**—Rost makes a further report on the treatment of leprosy by injections of leprolin. About 120 cases are being treated in Burma. Up to date 14 cases have been discharged as cured at Rangoon. Of 56 cases being treated by Rost 20 have so much improved that they may be said to be almost cured. In every case there has been marked improvement. The order of improvement is usually, first, a return of perspiration in a part previously dry, and then a return of sensation. This return of sensation may be only transient or it may be permanent. But ultimately it always returns on continuing the treatment. Second, there is a gain of strength and loosening of the contractions of the fingers and toes. Cases which have had very severe deformity and loss of power through contraction have completely regained their power and lost the deformity. Ulceration may give way to healing at once. In some cases thickened, hard epidermis has to be cut away before the ulcer heals. Nodules are usually slow to disappear. The color of the skin returns slowly. The pains in the limbs generally vanish early. The mental condition improves remarkably and with this the physiognomy improves. Local reactions after injection vary very much. Rost has given over 1,000 injections, and in no case was there any bad result nor was the disease enhanced thereby. In nearly all the cases the improvement has been obvious; in a few it is rapid, but in the majority the improvement has been slow, but steadily maintained. In some cases he has given as many as sixteen injections, and some cases did not show any sign of improvement until after the sixth injection. The difficulty in making a leprolin of constant strength makes it imperative to increase the dose if it is not found to cause a reactionary fever of over 100 F. The interval between the injections has been restricted to ten days, as some few days seem necessary to allow the patient to recover after the fever, besides which a too rapid recovery must not be expected in a disease which is so remarkably chronic. Evidently the action of leprolin is an antitoxic one and not an auto-antitoxic one. A detailed report of cases pronounced cured is appended to the article.

15. Influence of Displacement of Kidney on the Ascending Colon.—Alglave noticed in dissecting a cadaver that the cecum was displaced, swollen and compressed by a movable kidney. The functions of the cecum must have been seriously interfered with during life. Search for similar conditions in other cadavers showed 4 cases in the course of a few days, all in female subjects. He gives a number of illustrations of the findings, showing how the kidney, as it becomes displaced downward, drags down with it the adherent organs and especially the right angle formed by the colon. This kinks the colon. The consequent digestive and intestinal disturbances are not due directly to the displacement of the kidney, but the latter is the indirect cause. Nephropexy removes this cause, but, he adds, it is not always sufficient to remedy the conditions that have become installed, the kink in the colon frequently persisting unmodified by the nephropexy alone. If the kinked loop is much damaged, it may be necessary to exclude the ascending part of the colon by ileo-colostomy or ileosigmoidostomy. The latter is especially indicated when the liver is also displaced downward, and does not permit the intestine to resume its normal place.

16. Operative Injury of Thoracic Duct.—Lecène reports a personal case and reviews 21 in the literature. Operative injury of the cervical thoracic duct is not always perceived at the time of the operation, although the escape of lymph or chyle from the wound usually attracts attention. The patient suffers from thirst, emaciation, general asthenia and sometimes oliguria, the dehydration of the organism causing choleriform symptoms. Only one of the cases on record terminated fatally, and this was in 1875. If the injury is discovered at once, a ligature should be thrown around the peripheral stump of the severed duct. Ligature of the central stump is generally superfluous, as the valves are sufficient. Ligation of the peripheral stump does no harm, as has been established by clinical and experimental experience. The duct was sutured in one instance (Cushing), but this is indicated only in exceptional cases. If the injury is not discovered until later, pressure applied to the wound after removing the drain will generally result in a rapid cure. The wound may be opened and a ligature applied on the duct, and this has been done in some instances, but it is rather difficult and it is easy to cure without it. The success realized by simple, firm tamponing has been so complete that many authors advocate it, instead of ligation, for all cases, but Lecène would reserve it for the cases in which the injury was not noticed until later.

17. Perforation from Gastric Ulcer.—Gross' monograph has been running through the year, with an exhaustive survey of the literature, concluding with summaries of the details of 403 surgical cases. He has operated on 2 cases, with fine results in one instance. In this case there had been no melena nor hematemesis, and no bleeding point was found near the perforation, consequently the latter was merely sutured, without excision, in two tiers with fine silk. The peritoneum was then sponged dry. A drain was left in contact with the wound and another in the Douglas cul-de-sac. The patient was a farmer, 47 years old, a hard drinker, with stomach symptoms for two years. The success was evidently due to the fact that the operation was undertaken within three hours of the perforation. The stomach contents had not had time to induce inflammation of the peritoneum.

18. Cancer of the Thyroid.—Delore of Lyons states that cancer of the thyroid gland is particularly frequent there. He has observed 14 cases during the last three years, and Billiard has collected 83 from the hospital records, 15 in one-half year. The overwhelming majority are in women, and the subjects are generally younger than those with other forms of cancer. In a few cases developing at puberty, the course was fulminating. There is evidently a close connection between the cancer and preceding goiter.

20 *Des dangers de l'emploi du naphthol camphré dans la pratique courante. Cazin and Hallion.
21 *Les formes graves de la constipation et leur traitement chirurgical. F. Lejars.

20. Dangers of Camphorated Naphthol.—Guinard has recently reported a case of death less than an hour after injection of 25 c.c. of camphorated naphthol into a supra-clavicular cold, ganglionary abscess. The patient was a young man of 28. Guinard has found records of 12 similar fatalities after the use of this substance. There is a still larger number of cases on record in which convulsions and other symptoms of intoxication occurred, although the patients recovered. The doses were usually large, but in some of these cases not more than .5 c.c. had been injected, and half this amount in the case of one child. Desesquelle, who first used camphorated naphthol, expressly insisted that .2 c.c. for an adult and .1 c.c. for a child was the maximum daily dose. Disregard of his directions has led to accidents. Cazin and Hallion have been studying its toxic action on laboratory animals, and their results corroborate the experiences in the clinic. They conclude that one or two drops are enough for a ganglionary abscess, and a few drops in the drain tube leading to the peritoneum or pleura—no more under any circumstances. With these restrictions, camphorated naphthol can retain its place in the treatment of various affections in which it has proved its usefulness.

21. Surgical Treatment of Severe Forms of Constipation.—Lejars reviews some recent articles on this subject and styles constipation the "ill of the century." Surgical intervention, suppressing part of the large intestine, excluding or excising it, is a comparatively simple and benign operation, when done in two operations, first curing the stercoremia before completing the task. He adds that the large intestine, like the appendix, is an ancestral organ, ill suited for the conditions of modern life, and that it is destined to retrogress, atrophy and finally disappear. Like the appendix, its only function is becoming more and more merely a pathologic function. Surgery, in removing these organs, merely hastens the natural progress of evolution.

33 Practical Progress in Physicotherapy.—Staungshyperämie: Wärme und Kälte: Gas- und Wechselstrombäder. A. Laquer.

23. Brain Tumors.—In 2 of the 5 cases described the tumor was a cholesteatoma at the base of the brain. The patients were 40 and 45 years old; the structure of the tumors, their location and relations to the brain, and the microscopic and chemico-microscopic findings, sustain the assumption that cholesteatomata of the central nervous system originate in aberrant fetal epidermis germinal tissue.

24. Hysteric Sleep.—Raecke reviews 23 cases of hysteric sleep or somnolency. In 10 it had been preceded by hysteric convulsions; in 7 there were attacks of lethargy, while 6 others presented a protracted hysteric stupor which only at times appeared to be sleep, and alternated with periods of delirious confusion or general inhibitions with partial loss of consciousness. Hysteric conditions may be differentiated from epileptic similar conditions by the behavior during the intervals and by the history of the case, with examination of the pupil and of the tendon reflexes and evidences of old injuries, scars on the tongue, recent bruises or ecchymoses and the Babinski sign. It is difficult sometimes to distinguish between hysteric and catatonic stupor, but hysterics are more liable to assume comfortable positions, to attend to their bodily needs, to rouse at mealtimes and to display a certain amount of interest in their surroundings. Positive differentiation is possible only when the existence of hysteria can be determined aside from the stupor.

25. **Hypochondria.**—Schott regards hypochondria as an expression of degeneration, and warns against medication for it as a rule. When it accompanies a curable psychosis, it generally presages a protracted course. All peripheral sources of irritation should be removed in case of hypochondria so far as possible, and it should be borne in mind that the hypochondriac *is liable to commit suicide or to injure himself or those around* him.

26. **Psyche and Psychoses.**—Kronthal argues that the nervous system is a collection of innumerable routes for reflex action. The centers in the brain are merely the points where the circuit is closed between the sensory and the motor nerves. He asserts that the entire nervous system is merely a combination for the conduction of stimuli. This explains the decussation of nerves, as their crossing multiplies the number of possible reflexes. The sum of all the reflexes is the psyche. When an individual reacts in an abnormal manner to the impressions of the outer world we call the condition a psychosis. He adds further that sleeping and waking have nothing to do with the central nervous system. The individual sleeps when his cells are weary, intoxicated and unable to react further. He wakes when his cells have recuperated. He dreams when his cells react imperfectly to stimuli. Psychoses can occur without any participation of the nervous system. As the psyche is the sum of all the reflexes, a psychosis is inevitable when a number of the elementary organisms, the cells constituting the individual, respond to stimuli with an abnormal reaction. The reactions throughout the body become different with a varying temperature. In fever we should, therefore, expect an altered sum of reflexes, an altered psyche, and we find it in the delirium of fever. In alcohol intoxication likewise, the cells behave differently from normal, and the sum of the reflexes—the psyche—is likewise abnormal. When certain of the cells respond sluggishly and others with excessive excitability, we call this condition hysteria. He reviews the conditions in other affections viewed from this standpoint, affirming that this theory supplies a solid scientific basis for treatment of psychoses. They are merely the morbidly altered reaction of the individual, the result of a morbidly altered condition of the body. If we can succeed in making the body react normally once more then the psyche, the sum of the reflexes, will become normal again. There is nothing mystic about the psyche. It is merely the sum of the reflexes, and study of physiology and allied sciences is making physicians better and better acquainted with the reflexes and with the means of influencing them.

28. **Prognosis and Treatment of Diabetes.**—De la Camp reviews recent progress in this line, dwelling particularly on Naunyn's axioms: "The assimilating capacity of a diabetic decreases with *persistent glycosuria," and "The assimilating capacity* improves with persisting aglycosuria." They emphasize the importance of reducing the output of sugar as the main essential in treatment. Naunyn further affirms that every diabetic who requires treatment at all, should have his diet regulated both as to quality and quantity. It often happens that a patient is seen for the first time after some trauma, excess or other injurious influence, and the affection is supposed to be severe when it subsides afterward into a much milder form. Others give the impression of being mild, but grow rapidly worse. Such subjects are generally young. Even when the diabetes apparently subsides completely, it probably still persists in a latent form. The glycosuria may vanish when nephritis becomes installed, but this is no gain for the diabetic. Pregnancy is an unfavorable complication. Roff states that 50 per cent. of pregnant women suffering from diabetes succumb in coma. Progress has been realized in the dietetics of diabetes by von Noorden's discovery of the remarkable tolerance of diabetics for oatmeal. (See The Journal, xli, page 1374.) De la Camp has observed a case in which a woman, 35 years old, gained over ten pounds in weight in three weeks on a daily ration of 250 gm. oatmeal, 100 gm. butter and 4 eggs, a total of 2,500 calories. She had 8.1 per cent. sugar in 3,200 c.c. urine smelling strongly of acetone. The output of carbohydrates was 259, with an intake of 293. She was given from 20 to 60 gm. of sodium bicarbonate a day, the larger amount being necessary to render the urine alkaline. The output of sugar and the acidosis remained at the same figures, without retention of water.

30. **Syphilis Acquired by Physicians in the Exercise of Their Profession.**—*Blaschko states that he has had occasion* to observe 12 cases of syphilis in physicians during the last ten years, acquired in the exercise of their profession, 10 in Berlin alone. As the primary sore develops on the fingers as a rule in these cases, it is generally unrecognized and taken for a panaritium. Its nature is first suspected by its protracted course, the bluish infiltration and the aspect of the depths of the lesion. In 2 cases there was mixed streptococcus infection, with a torpid lymphangitis and numerous small superposed buboes. Herpes on the finger, cadaver tubercle and soft chancre present different symptoms, the first being preceded by neuralgia in the nerve involved and the entire process terminating in about ten days. Soft chancre rapidly heals under carbolic acid and iodoform. In other cases the syphilitic primary sore was very small and soon healed without a scar. The outbreak of general symptoms or the development of very large indolent buboes was the first sign that attracted attention. In one case the primary sore was on the face. In another instance a roseola broke out over the entire body without any premonitory signs of trouble, and not a single point of entry for the virus could be discovered on the patient. He was a very careful, conscientious and painstaking physician, and the fact that such a trained observer was unable to discover the portal of entry for the virus suggests the possibility of a syphilis without the primary lesion, the "*syphilis d'emblée*" of the French. The infection seems to have been generally acquired during the extirpation of a bubo or something of the kind. None was referable to infection from an instrument which had recently been used on a syphilitic subject, although such a possibility should never be ignored. The erosions at the base of the nails from scrubbing were generally the entering point. The danger from this source is particularly great in case of abortions or of premature births, as these so frequently occur in syphilitic women. In one case infection was unmistakably derived from dissection of a syphilitic cadaver twenty-four hours after death. Blaschko urges that every physician should bear in mind the possibility that the patient before him may be a syphilitic in every case in which he has to use the knife or to make a bimanual examination. At present only those particularly engaged in practice among syphilitics ever seem to think of this possibility. Modern methods of cleaning the hands invite erosions, etc., and he thinks that too little stress is placed on cleansing the hands *after* operations, and that they suffer from the excessive scrubbing before. *Every wound, every crack,* should be carefully covered. His practice is to touch them with a 2 to 3 per cent. solution of silver and thus produce an impermeable covering of silver albuminate. This he covers with a small scrap of adhesive plaster with collodion outside or, better still, a finger cot. He advises rubber gloves or cots for all gynecologic examinations in the interests of both patients and physician. When infection has once occurred, silver nitrate and sublimate, even at once, have proved ineffectual to abort the process. His practice is to rinse the scratch copiously with water and then pour tincture of iodin into the wound. Possibly hydrogen dioxid might be effectual. He once used on himself an electrolytic needle when he received a scratch while

puncturing a bubo. He burned out the spot the next day with the actual cautery and never has heard anything further from it. He believes in treating syphilis only when indicated by symptoms. His medical patients were inclined to err on the side of excessive treatment. and severe physical and psychical depression was the result in some instances. He thinks that the fact of the existence of the syphilis need not interfere with the subject's professional work under certain obvious restrictions as, for instance. when there are lesions on the hands. The physician himself is usually the best judge as to this. He does not know of any instance in which the disease was transmitted farther by the physician affected His family life suffers more than his professional. but the medical profession, Blaschko adds, frequently requires great sacrifices from its members. and experience has shown that they are borne with courage and dignity even under these circumstances

34. **Vaginal Ovariotomy.**—Bürger reports from Schauta's clinic 110 cases of ovariotomy by the vaginal route. The contraindications accepted are the same as in other clinics, with the exception that Schauta prefers the vaginal operation even for cysts filling the entire abdominal cavity, if there are no contraindications of other kinds. The particulars of the various groups of cases are described, the results, immediate and remote, confirming the opinion that vaginal ovariotomy is a harmless operation. with a rapid and smooth recovery, which does not entail any appreciable consecutive disturbances Menstruation recurred in the 22 women examined in this respect in an average of about five weeks, while the average after abdominal ovariotomy has been ten and eleven weeks in his experience.

41. **Leucocyte Count in Appendicitis.**—Federmann emphasizes that a high leucocytosis in the first days of appendicitis indicates that the organism is actively at work struggling with its invaders. An operation undertaken in these conditions has a good prognosis. His experience has been that a high leucocyte count indicates a severe infection, but is no criterion as to the presence of pus.

42. **Intermittent Dilatation of End of Ureters.**—König writes from Altona to describe a case of urinary disturbances in which the cystoscope showed that the vesical end of the ureters became intermittently dilated, forming a cyst, which finally emptied its contents under vigorous contractions of the bladder wall. the cyst subsiding completely, leaving the orifice normal. The lower end of both ureters was evidently dilated and as urine accumulated the cyst formed. He has found 50 similar cases recorded in the literature. His patient was an otherwise healthy man who had suffered from childhood with desires to urinate and difficulty in urinating. During the last year blood and hemoglobin were noted in the urine after exertion Garré operated on such a case, curing his patient, a young man. of serious urinary disturbances

43. **Cure of Stiff Elbow.**—Schanz operated on the elbow as usual, but to prevent recurrence of the ankylosis, he interposed between the raw surfaces of the bones a pedunculated flap of subcutaneous adipose tissue, tying it in place so that it could not slip out. The cast was removed in about a month; in three weeks the patient could use her arm freely and in three months after the operation could brush her hair, eat, etc., with apparently normal function of the arm. There was no pain at any time. The thick flap prevented the growth of connective tissue adhesions, while its porous character allowed movements impossible with a denser tissue. It is possible that a kind of bursa may have formed in the fat. He expects to apply this technic to other joints as occasion arises.

44. **Climate and Tuberculosis.**—Besold thinks that better results will be realized when more attention is paid to individualized treatment and less to climate in tuberculous cases.

46. **To Prevent Leaving Sponges in Abdomen.**—Calmann has a long tape fastened to each of his compresses and sponges The ends of the tapes are taken up in a bunch and tied around one of the legs of the table, at the head, on the side where the instruments are handed to the operator. The tapes are long enough not to interfere with the use of the sponges in any way.

48. **Heredity of Syphilis.**—Jesionek has had occasion to observe several occurrences which have convinced him that the semen of a syphilitic is able to induce contact infection. Also that the semen can transmit the syphilis of the father to the offspring. He thus accepts paternal transmission of the disease and the "choc en retour," that is, infection of the mother from the infected fetus. Among the evidence which he cites to support this view is the family experience of a physician—a trained observer—after professional infection from an obstetric case.

54. **Cachectic Leucocytosis.**—Arneth tabulates the blood findings in 12 cases of cancer, mostly gastric cancer. They show that secondary anemia and cachexia may develop in case of uncomplicated cancer without much impairment of the leucocytes or influence on their numbers. But the coincidence of a complication affects the leucocytes materially, the blood then presenting the aspect which he has previously described as anisohypocytosis or anisohypercytosis. In one extreme case, the carcinosis involving the entire body, the reds presented the aspect of true pernicious anemia, while the neutrophile leucocytes presented that of leukemia. In future a distinction must be made between the blood findings of uncomplicated cancer and those for which the complications are responsible.

60. **Blood Pressure in Arteriosclerosis.**—Dunin has measured the blood pressure 1,000 times in 440 patients with arteriosclerosis, in his private practice. He used Gaertner's tonometer exclusively. In 120 out of 420 arteriosclerotic subjects he found the blood pressure normal or below. In all the other patients the blood pressure was above normal. In 36 out of 80 cases with low blood pressure angina pectoris was observed. In 8 cases the sharp accentuation of the aortic second sound was the only symptom on the part of the vascular system. The blood pressure in this group was only 90 mm. to 140 mm. The first sound was weak. In 2 patients there was also a diastolic murmur. None in this group complained of any heart trouble. In another group of 14 cases there were pronounced subjective disturbances and corpulence, and changes were found in the heart, or aorta, with signs indicating dilatation of the arch of the aorta and sometimes also of the aortic orifice. A further group of 22 presented the same findings with the exception of the corpulence. In all his cases of normal or low blood pressure the arteriosclerosis was evidently restricted to the large arteries, while the smaller were intact. Most of the patients were middle-aged. although some were quite young. In 35.7 per cent. of 380 cases of arteriosclerosis corpulence was noted, the proportion being higher among the subjects with high blood pressure. Reduction of the corpulence frequently restored the pressure to normal. Functional over-pressure he found very rare. Therapeutic measures to reduce the blood pressure were seldom successful except in cases of corpulence, although the general condition was much benefited by hygiene and measures to tone up the nervous system and the heart muscle. So long as the heart is sound and vigorous the changes in the arteries are effectually compensated. Long-continued over-pressure entails hypertrophy of the left ventricle, although it may not be clinically evident. Measurement of the blood pressure may thus determine the size of the heart better than mere percussion. He found the pulse rapid in 40 out of 136 cases of high pressure. In one instance the pressure was 240, the pulse 200; in another, with a pressure of 250, the pulse was 120. Fully 25 per cent. of these patients were neurasthenics. Tachycardia with high pressure presages the approach of disturbances in compensation.

61. **Measurement of Diastolic Blood Pressure.**—Strasburger's technic differs from Janeway's and Masing's in that he uses the palpating finger instead of the sphygmograph, and, instead of determining the average blood pressure, lays most stress on the extremes found. Comparison of the height of the diastolic pressure with that of the systolic pressure, and determination of the blood-pressure quotient, show the reciprocal relations between the tension of the vessels and what the heart is able to accomplish. The condition of the circulatory system can be ascertained by study of the systolic pressure and of the blood-pressure quotient better than by any means known to date, especially in respect to the functional capacity of the heart and the blood supply in the tissues. He states that such results have been obtainable hitherto only by measuring the blood pressure in the severed artery of a living animal. His "pressure quotient" is obtained by subtracting the diastolic pressure from the systolic, the remainder found being what he calls the "pulse pressure." The ratio between the pulse pressure and the maximal pressure is his "blood pressure quotient." It affords an insight into the relations between the work accomplished by the heart and the resistance in the arterial system. He tabulates the findings in a large number of cases of various affections and in normal subjects. He also shows in a diagram the various conclusions that may be deduced from the different groups of findings.

62. **Bacteriemia.**—Jochmann reviews the results of bacteriologic examination of the blood on a large clinical material. They demonstrate the great importance of this means of investigation, both from a diagnostic and prognostic standpoint and also as a guide for treatment. His findings in 161 clinical cases and 70 cadavers have convinced him that scarlet fever is not a streptococcus affection. As germs in the blood increase rapidly immediately after death, the frequent negative postmortem findings, even in the fulminating cases of scarlet fever, were very significant. His findings were also negative in 18 cases of acute articular rheumatism. Even the exudation aspirated from the joints in 11 cases always proved sterile. The bacteriemia is sometimes the only sign of typhoid fever, and is almost constant during the acme of typhoid. Gonococci were found in the blood in 2 out of 3 cases of gonorrhea, one patient recovering.

65. **Sigmoiditis.**—Rosenheim relates the particulars of 11 cases, showing the importance of direct inspection of the sigmoid flexure in dubious cases of intestinal trouble. It may reveal a local inflammatory process restricted to this region and amenable to treatment. Rest, oil injections, belladonna and morphin aid in inducing a complete cure. Pains in the left side, diarrhea or constipation and fever, sometimes local hemorrhages, may be the principal symptoms. He uses the endoscope when introducing the tube for local medication.

66. **Myelocytes in the Blood.**—Schindler's extensive research has shown that conditions inducing leucocytosis may cause the myelocytes to pass into the blood. This is currently observed in infectious diseases, and has no special significance if the myelocytes vanish as the leucocytosis subsides. If they persist, their presence indicates functional exhaustion of the elements of the marrow. The toxins of certain diseases, typhoid fever and malaria, have an inhibiting action on the leucocyte-forming tissues. The myelocytes appear in this case as the evidences of abnormal reaction on the part of the marrow to the irritation. In malaria, his findings show that the leucocytes increase as the temperature rises and diminish during the intervals. In some cases of malaria the blood findings are exactly like those of pernicious anemia.

67. **Urea and Ammonia in Symptomatology of Liver Lesions.**—De Rossi reviews the present status of our knowledge on this subject, and analyzes four instructive cases. He thinks that it is established that all the organs form urea in proportion to their size and their nutrient interchanges. It is not the property of the liver alone. Also that the albumin molecule takes various ways to form urea, and not merely that of the ammonium salts alone. Also that the elaboration of urea is, in all probability, not a simple process and, above all, not a single one. The nitrogenous compounds in the urine vary in individual cases of liver affections according to the general conditions of metabolism, not necessarily merely according to the lesion in the liver. The only finding that occurs with any regularity in these cases is an increased amount of NH^3. But even this finding is not directly proportional to the liver lesion, but depends more on the condition of the circulation and on the acidity of the tissues. The practical conclusion from the above is that alimentary ammoniuria is not a reliable test of the functioning of the liver.

68. **Operation for Exstrophy of Bladder.**—Müller proposed in 1903 a mode of operating on subjects with extroversion of

the bladder, but he had not attempted to execute it on the living subject. Muscatello here reports a case in which he followed the suggested technic with one slight modification. The results compel him to rank it above all other methods yet presented. Its principal advantage is that it protects the ureters against contact with feces after they have been transplanted in the sigmoid colon. This is accomplished by dividing the colon and suturing it together again after exclusion of a short portion. The part of the bladder containing the trigone and the mouths of the ureters is then transplanted in the excluded portion of the colon. This brings the ureters into a blind pouch at some distance above the point where the mouth of the pouch opens into the sigmoid colon. The top of the blind pouch formed by the excluded part of the gut is fastened with a few stitches to the colon above the anastomosis, thus retaining the connection between the excluded portion and the rest of the bowel. Müller proposed to fasten the excluded portion to the anterior abdominal wall, which might result in the kinking of the ureters, etc. The patient in the case described had been treated by the Maydl technic at first, but without success. The second intervention, according to the Müller technic, resulted in a complete cure of his deformity. The wound had healed completely in less than four weeks. The article is illustrated.

75. **Barium Chlorid in Therapeutics.**—Pesci has been testing barium chlorid in 40 cases of various affections, including 11 of pleurisy, 8 of valvular defects, 4 of myocarditis, 3 of typhoid, etc. He studied the temperature, pulse, respiration, arterial pressure, urine and ingestion of fluids in the various cases while under the influence of the drug. The results confirm those reported by Schedel, Tabora and others in respect to the efficacy of barium chlorid as a pressure-raising drug and diuretic. The pressure was raised from a few mm. to a maximum of 60 mm. in his experiences, both clinical and experimental. It rose a few hours after taking the chlorid, and constantly increased to a maximum at which it persisted for three or four days, then gradually subsided, but still kept for a time longer above the previous figure. In the very severe cases the pressure sank after the first rise —a sign of grave prognosis. In some cases there was no appreciable action on the pressure, but the general condition showed marked improvement, sometimes with diuresis. In every case, however, the pulse tracings assumed a more normal type, the pulse findings explaining the general improvement that followed the use of the drug. No injurious action was noted in any case. The prompt diuresis that followed in cases of pleurisy was the most gratifying result noted, in some instances the benefit being truly marvelous, the amount of urine excreted increasing from 1,000 to 4,000 c.c. The dosage was 43 cg. in three days, 60 cg. in four days, or 32 cg. in three days. He advocates the drug, therefore, as the best diuretic for pleurisy, the benefit being prompt, constant and superior to that of any other diuretic with which he is familiar. The drug is also indicated in the first stage of disturbance of compensation in a valvular affection, when the circulation is sluggish and the relaxed walls of the arteries allow infiltration of the tissues. Barium chlorid stimulates the musculature of the walls of the arteries. It is also useful for the same reason in infectious disease when the pulse is becoming dicrotic from relaxation of the walls of the vessels and weakness of the intoxicated myocardium. Barium chlorid arrests these disturbances or prevents them by its beneficent influence on the disease itself Excessively high blood pressure with weak heart is the only contraindication.

84 (No. 10.) *Statistics of Japanese Naval Officers and Men Killed or Wounded in Present War.

80. **The Anopheles During Hibernation.**—The results of extensive personal research are given in this illustrated article. Suzuki thinks that the female alone survives the winter. It usually contains fertilized eggs, and as soon as it regains its vitality, when thawed out by warm weather, it lays the eggs. He found mature eggs in both the anopheles and culex during their hibernation.

82. **The Japanese Hospital Ship.**—This floating hospital has been described previously in THE JOURNAL. It did good service during the war of 1894-5 conveying the wounded from the seat of war to the home hospitals. In the illustrated description we note that 126.5 cubic feet of space are allotted to each patient in the general room, while the seriously wounded have each 416 cubic feet and the infectious cases 266.5. The Sei-I-Kwai urges the necessity for installation of a refrigerating machine and electric fans, to complete the equipment.

84. **Killed and Wounded in Japanese Navy.**—The tables give 1,022 killed and 556 severely wounded, the total injured being 2,321. Six navy surgeons have been killed and six have had dysentery or typhoid fever. Thirteen "medical attendants" were also killed and the same number have had some infectious disease. The medical cases all recovered. The statistics cover the period from Feb. 9 to Oct. 10, 1904. They are grouped by the various engagements, almost all at Port Arthur.

85. **Malarial Affections of Nervous System.**—Dobrokhotoff's article reviews the various nervous affections due to the malarial parasite, the clinical pictures drawn from his own experience and study of the literature. The malarial psychoses generally develop with depression; neuralgia, neuritis and localized focal affections of the central nervous system are not rare. More diffuse troubles, such as multiple sclerosis, also occur as the result of malaria. He gives the details of a striking case of malarial multiple sclerosis. The parasites in the circulation injure the endothelium of the vessels either directly or by their toxins, or by the products of the destroyed red corpuscles. The changes thus induced in the endothelium cause thrombosis in the capillaries, and injure the walls of these vessels. The capillaries in the brain are particularly liable to these injuries, with consecutive hemorrhages. He thinks that these changes in the capillaries explain the conditions noted in the parenchymatous elements of the liver, spleen, kidneys and ganglion cells in malaria. The prognosis is favorable for these nervous affections on a malarial basis, with the exception of the comatous form. They gradually subside under quinin to apparently complete restitution.

86. **Acute Endocarditis.**—Martzinovsky believes that acute endocarditis may result from the action of one or more of several bacteria. At least 10 c.c. of blood should be taken for bacteriologic examination, as the number of microbes in the blood is not necessarily large. Both aërobic and anaërobic cultures should be made, and a negative result does not exclude endocarditis. He was able to discover a connection between the endocarditis and erysipelas, with streptococci, in one case, and between a diplococcus endocarditis and croupous pneumonia in another. He found acute endocarditis in about half of his cases of rheumatism, but the bacteria differed in the various cases, so that the assumption of a single causal germ for acute articular rheumatism seems highly improbable. In his experience, acute endocarditis was frequently followed by progressive anemia and icterus, with urobilin, albumin and casts in the urine. The most promising treatment for acute endocarditis seems to be with an appropriate serum, but this will require early and repeated examination of the blood to disclose the kind of antiserum needed. His article is based on a study of 30 cases.

87. **Perineal Prostatectomy.**—Gerzen reviews the literature on this subject, including much of the American, and describes a case of his own. He commends the perineal operation to his countrymen as destined to an important place in the treatment of enlarged prostate.

88. **Epididymitis.**—In a case described by Krimoff a trauma had induced aneurism of the spermatic artery and epididymitis. The latter may be due to gonorrhea, tuberculosis, syphilis or to casual microbes, as he demonstrates from his experience.

90. **Cancer of Vater's Ampulla.**—Kusheff asserts that cancer at this point can be diagnosed from the progressive emaciation of the subject with icterus but no fever nor catarrhal symptoms on the part of the stomach or intestines. In 2 cases described, cholelithiasis could be excluded as also hypertrophic cirrhosis of the liver. There was no ascites, and no tumor could be palpated. His patients were men of 57 and 75, respectively. The cancer in each was an adenocarcinoma.

93. **Sudden Death in Diphtheria.**—Krasnoff's experimental researches have resulted in a confirmation of his belief that sudden death in diphtheria is due to paralysis of the diaphragm.

94. **Eye Symptom of Diffuse Sclerodermia.**—Lozhetchnikoff calls attention to the bilateral, symmetric immovability of the eyeball in diffuse sclerodermia. The process has evidently involved the muscles of the eye when this stage is reached. He observed this symptom in a girl of 17, and she improved under hot baths and massage until even the eye symptom entirely disappeared. He reports the case as one of cured sclerodermia.

95. **Bone Formation in Heart Valves.**—In the 4 cases described there was an unmistakable formation of bone in some of the valves and even in the heart itself. The subjects were elderly men.

96. **Etiology of Chorea.**—Study of 124 cases of chorea at the Moscow hospitals has established, to the satisfaction of these authors, that articular rheumatism, endocarditis and chorea form a triad for which one and the same cause is responsible.

101. **Experiences with Talma Operation.**—Kozlovski gives the particulars of 5 cases of ascites from cirrhosis of the liver, treated by omentopexy. Two patients were apparently much improved but their ultimate fate is not known. Two others were much improved and lived five and eleven months. In one the ascites recurred after a few months. One patient died in less than a month. The particulars of seven similar operations by other Russian surgeons are also given.

102. **Retinal Hemorrhages in Parasitic Anemia.**—Tchemolosoff adds two cases to his first series of four with anemia and retinal hemorrhages due to the presence of the *Ankylostomum duodenale*. All the cases terminated fatally, notwithstanding prompt differentiation and treatment. The eye of one of these patients was submitted to minute microscopic examination, the results of which are given in detail.

110. **Action of Radium on Typhoid Serum.**—Yagn made 19 tests of the serum of typhoid patients, exposing it to the action of the radium rays. He found that long exposure completely checked agglutination. Exposures less than two or three days in length inhibited, but did not completely arrest the agglutinating property.

Books Received.

CONSERVATIVE PERINEAL PROSTATECTOMY.

A REPORT OF FIFTY CASES.*

HUGH H. YOUNG, M.D.
Associate Professor of Genito-Urinary Surgery, Johns Hopkins University; Head of the Department of Genito-Urinary Surgery.
BALTIMORE.

One year ago I presented to the American Association of Genitourinary Surgeons a paper entitled "Conservative Perineal Prostatectomy—A Presentation of New Instruments and Technic."[1] Since then I have further elaborated the technic, and it is my purpose to-day to outline the results obtained in 50 cases in which I have employed this method.

In using the word conservative, I do not wish it to be understood as opposing radical surgery for the prostate, but simply as an advocate of the conservation of those structures which are in no way concerned in the obstruction to free micturition, and are of themselves of independent importance, viz., the preservation of the urethra and of the ejaculatory ducts. By means of the 50 cases which I report I hope to make it clear that both of these structures need not be uselessly sacrificed or injured and that their preservation in no way detracts from a perfect functional result, so far as the restoration of normal urination is concerned, but also that the virility of the sexual powers will be generally left unimpaired.

I hope I will be pardoned for outlining here briefly the principal features of the technic already described. The form of perineal incision is of no particular consequence but, as the operation which I employ is carried out between the bulb of the urethra and the anterior surface of the rectum, I have usually made my cutaneous incision so as to give the best exposure to this region—an inverted V, with the apex over the posterior part of the bulb and the branches extending to a point between the anus and the ischial spine on each side (Fig. 1). This incision, although only carried through the skin and superficial fascia, allows the rectum to be retracted backward with ease, giving a splendid exposure. The only muscular structures divided are the central tendon of the perineum (Fig. 2) and the rectourethralis muscle which lies immediately beneath it (Fig. 3) and covers the membranous urethra and apex of the prostate. This small muscle, as Proust has shown, is the key to the situation, because it draws the rectum forward nearly up to the triangular ligament, where it is in great danger of being injured, if the rectourethralis is not carefully divided before going deeper, and because it also covers the entrance to the retroprostatic space which forms the field of work. The membranous urethra having been exposed, a small longitudinal incision is made on the grooved staff in the urethra (Fig. 4), the edges are carefully caught with forceps, an ordinary sound is passed through into the bladder to enlarge the canal, after which the prostatic tractor (Fig. 5) is inserted and opened out (Fig. 6).

When traction is made, the posterior surface of the prostate emerges at once from its hidden site in the depths of the wound, and the operator is free to carry out any maneuvers which he may desire (Fig. 7).

After having previously performed many suprapubic and perineal operations in the dark, depending entirely on the sense of touch, and glad enough to remove almost any portion of the prostate that I could get hold of, regardless of the urethra, etc., it occurred to me in the third perineal case with this tractor that it was a pity to sacrifice undoubtedly valuable structures, portions of the urethra and ejaculatory ducts, when the prostate could be so drawn down that it lay almost in the surface of the wound ripe for any nicer procedure which one might wish to execute.

I determined, by study of anatomic and pathologic specimens of the prostate, that two divergent incisions (Fig. 7) could be so made through the posterior surface of the prostate as to preserve between them the ejaculatory ducts and the floor of the urethra, without retaining any obstructive tissue (Figs. 8 and 9), and that if a median bar or lobe were present, it could be easily drawn by the tractor so as to project into one of the lateral cavities, and there be enucleated from its side, without disturbing the ejaculatory ducts, or even the urethra (Fig. 10).

That this assertion, which I offered at first with considerable hesitation, is undoubtedly true, I can now, on an experience of many middle lobe cases, affirm with great positiveness—and this without leaving behind any portion of hypertrophied tissue sufficient to produce obstruction of free urination. It has also, contrary to my expectation, proved applicable to all forms of median lobe enlargement, including even enormous intravesical outgrowths (one of which was as large as an orange and weighed 240 grams.) I am free to admit that in some of these cases the median enucleation might have been done more quickly from a suprapubic wound, but the middle lobe was always often associated with lateral enlargements which would have been more difficult to remove by that route, and the prospect of a much shorter convalescence and less operative risk, put me on my mettle to accomplish the more ideal, though more difficult, feat. Another reason has been that I have always been able by spinal cocainization to get excellent anesthesia of the perineum and prostate, whereas I have failed to get like good results for the suprapubic route.

---

* Read in the Section on Surgery of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904. The discussion on the symposium on prostatectomy, of which this article was a part, appeared in THE JOURNAL, Nov. 12, 1904, page 1452.

[1] Published in THE JOURNAL A. M. A., Oct. 26, 1903.

THE USE OF THE INDEX FINGER AS A TRACTOR.

There are some cases, however, in which the median enlargement is in the shape of a small bar or lobe, so adherent that it is difficult to engage it with the blade of the tractor, as described in my first paper, and for these I have of late employed the index finger of the left hand in place of the tractor in the urethra, to push the lobe into the lateral cavity. After the tractor has been withdrawn the finger is inserted gently through the opening, down the prostatic urethra, until the end is free in the bladder. Examination will then reveal the median bar or lobe which remains, and it is an easy matter, by crooking the finger over it, to carry it into the left lateral cavity where it can be enucleated (Fig. 11). If an adherent bar is encountered a fairly sharp periosteal elevator is a good instrument with which to peel it out. Occasionally it may be necessary to use scissors for this purpose, and to get hold of the mass to be removed as it begins to be separated, some long forceps may be required.

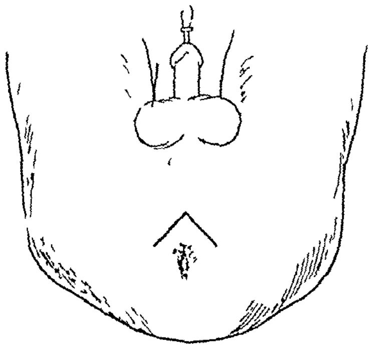

Fig. 1.—The inverted V incision

A very small rounded or pedunculated median lobe has been, in several of my cases, impossible to engage with the blade of the tractor, but I have been able, by using the finger instead of the tractor, to successfully remove it without injuring the urethra or the ejaculatory ducts. The technic described above is entirely different from that of Albarran, who draws the median lobe into the widely opened urethra with the finger, the portion of the prostate containing the ejaculatory ducts being destroyed, as he admits. He even goes so far as to ligate the vasa-deferentia in the groin after perineal prostatectomy has been completed, on the ground that the ejaculatory ducts have already been destroyed, and vasectomy will prevent epididymitis, which occurred in a large percentage of his cases.

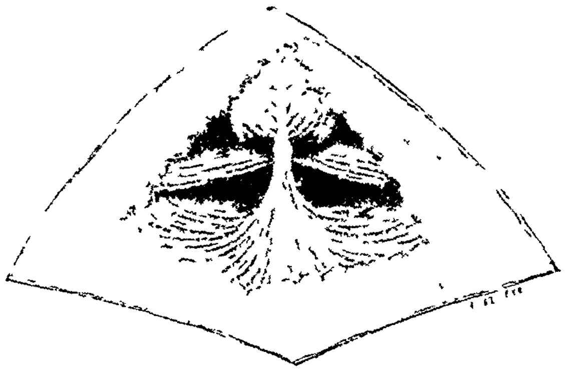

Fig. 2.—Central tendon of perineum exposed by blunt dissection

The following case illustrates the value of the modification of technic described above:

No. 493.—J. T. M., 54 years. Admitted Oct. 23, 1903.

History.—Frequency of urination beginning 15 years ago; considerable difficulty in voiding urine for past 10 years. One year ago he urinated every hour night and day—after that incontinence. He has been using a catheter for a short time.

Examination.—Prostate small and hard. Cystoscope showed small median lobe and slight lateral enlargements. The urine was acid and purulent. Residual urine, 500 c.c.

Operation.—Ether anesthesia. Enucleation of lateral lobe, which proved very small, a median bar and a pedunculated middle lobe the size of a pea. Urethra, bladder and ducts were left intact. Lateral lobes and median bar were easily removed with the assistance of the tractor in the bladder. The pedunculated median lobe was so small that it could not be engaged with the blade of the tractor, but after this instrument had been removed the index finger was introduced, as shown in Figure 11, when it was easily shelled out, although only about 8 mm. in diameter (Fig. 12). Total weight of prostate was less than 15 gm. Median lobe, about 2 gm. Double drainage No shock.

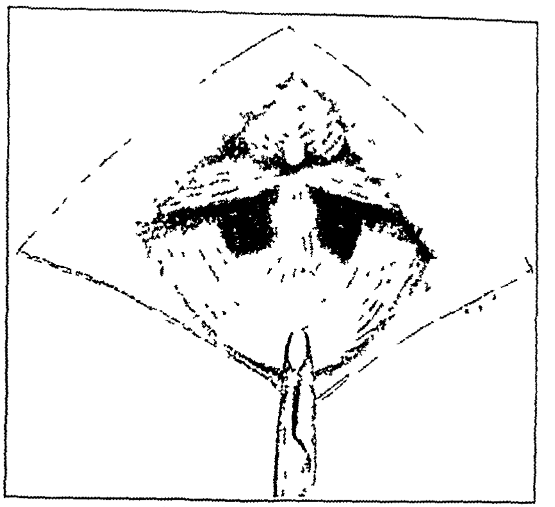

Fig. 3—Central tendon divided, exposing rectourethralis muscle

Result.—Convalescence was rapid. The patient left for home in third week. Interval between urinations was then 4 hours; residual urine 40 c.c., erections had returned. Perineal wound closed in the fourth week.

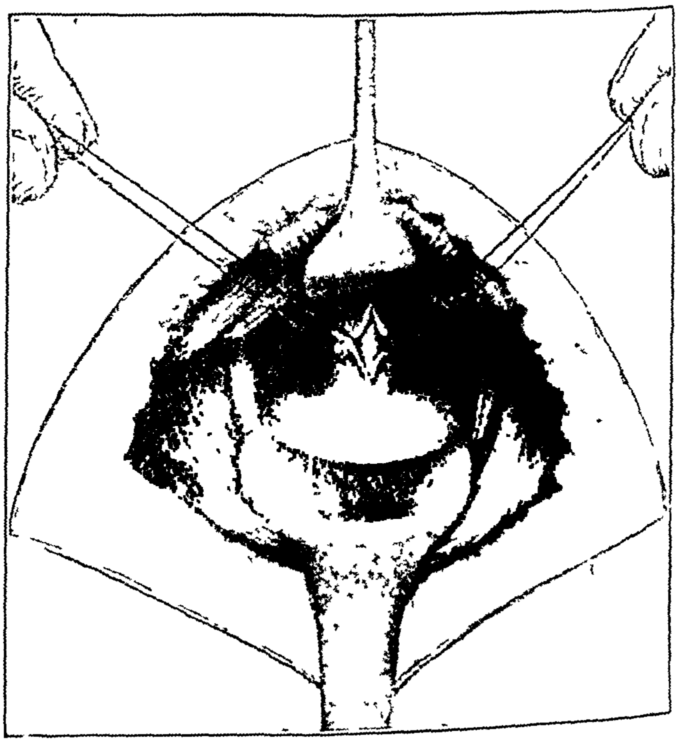

Fig. 4—Incision of membranous urethra for introduction of tractor.

Report several months later: Urination free, about 500 c.c at a time, at intervals of three hours. No residual urine, no incontinence. *Erections, coitus and ejaculations normal*

A very pedunculated middle lobe may evade both the finger and the tractor, and in such instances it may be best to insert a curved clamp and draw the middle lobe down the dilated urethra where it may be enucleated or divided with scissors. This is the technic employed by Albarran.

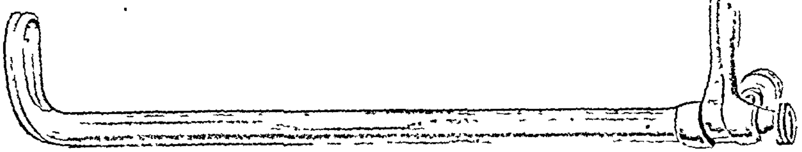

FIG. 5.—Prostatic tractor closed for insertion.

A SUBURETHRAL METHOD OF REMOVING A MEDIAN BAR OR LOBE.

In case the patient has already lost his sexual powers the reason for preserving the ejaculatory ducts does not hold, and in such cases, when the median bar or lobe is too small or too adherent to be delivered into a lateral cavity with the tractor, I have removed the mass suburethrally, after transverse division of the ejaculatory bridge as shown in Figure 13.

After stripping back the capsule (Fig. 14), it is an easy matter to shell out or to excise the median bar or lobe without opening the urethral or vesical mucous membrane covering it, as shown by the following case:

No. 528.—R. M. W., 78 years of age. Admitted Jan. 9, 1904.

History.—Onset occurred 18 years ago, with gradual increase in difficulty of urination. In 1901, he often voided urine 30 times during a night; he used a catheter only occasionally. In April, 1901, double castration was performed by another surgeon with only slight benefit. He now voids urine very frequently, at times, every hour.

Examination.—Condition was good for his age. Arteriosclerosis slight. Urine was acid and moderately purulent. Prostate was considerably enlarged. Catheter was difficult to pass—urethral distance eleven inches. The cystoscope showed a median bar, a fairly large left, and a similar right lobe.

Operation.—Spinal anesthesia by cocain, gr. 1/3. Enucleation of large lateral lobes and small median bar, as shown in photograph (Fig. 15). The "ejaculatory bridge" was purposely cut to remove the bar, which was enucleated as described above. Urethral and vesical mucosa covering the bar was not torn. The lobes weighed 74 gm.; the median, 7 gm The patient was up in a wheel-chair on the third day, tubes out on the fourth day.

Report: Five months later, he does not have to use a catheter—can empty bladder. Fistula closed. No incontinence. No residual urine, but cystitis and some vesical contracture are present. Micturition about every two hours. The patient had no after-treatment, and the frequency of urination could be relieved by dilatation of the bladder by hydraulic pressure.

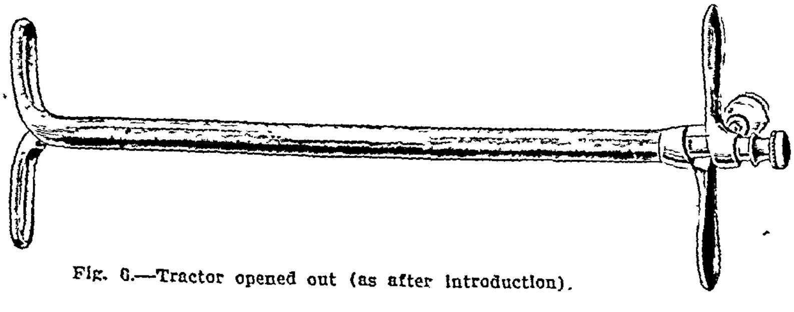

FIG. 6.—Tractor opened out (as after introduction).

TREATMENT OF VESICAL CALCULUS AS A COMPLICATION OF ENLARGED PROSTATE.

In the great majority of cases the median mass can be enucleated through the lateral cavity—the larger the lobe, the easier it is.

In my first 100 cases of prostatic hypertrophy, calculus was present in about 30 per cent., and, although the proportion has not been so great in these 50 cases of perineal prostatectomy it has occurred frequently enough to be an important factor in the operation. Either litholapaxy, before or during the prostatectomy operation, or suprapubic or perineal lithotomy may be performed. Without going into the arguments for or against either of these procedures, it is evident that if a perineal prostatectomy is to be performed the ideal procedure is to remove the calculus at the same sitting, without crushing it, for litholapaxy is in these cases a tedious procedure. If, however, the removal of the calculus intact will seriously injure the urethra, the ejaculatory ducts or the neck of the bladder, such a method is contraindicated. To drag a calculus by main force out through the urethra, as it is left by the technic which I follow, would be at once dangerous and destructive, except when it is small.

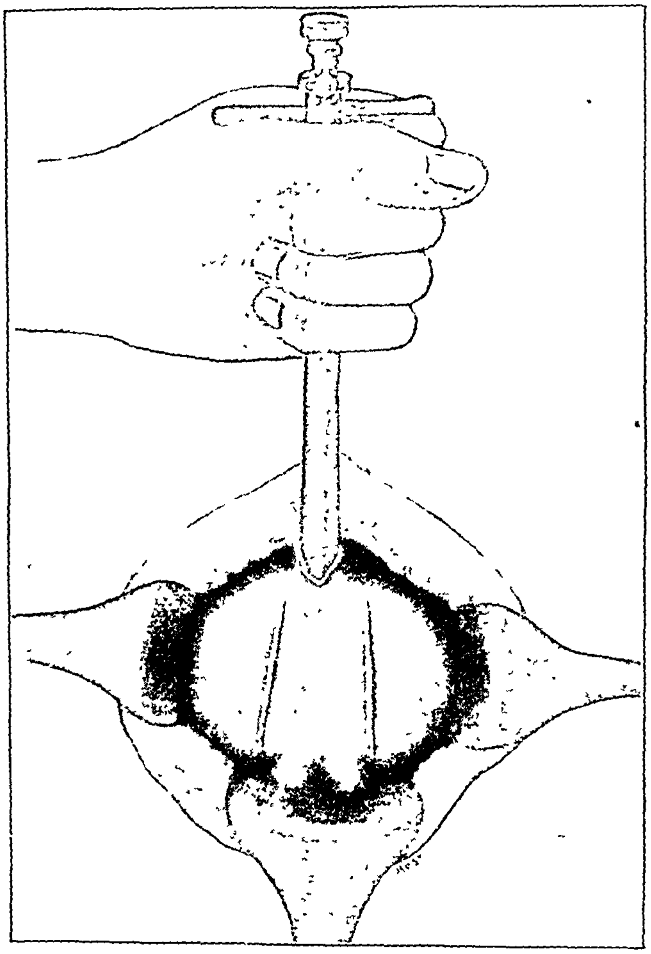

FIG. 7.—The prostate drawn down by tractor.

I have therefore endeavored to devise a method which would be free from the dangers mentioned above, and which would also provide for the removal of moderately large stones. The technic which I have found most satisfactory is graphically shown in the accompanying drawing (Fig. 16).

As seen here, the urethra is split with scissors along its left lateral wall, from the urethrotomy wound in the membranous urethra up to its vesical orifice. By this procedure, the urethra becomes a common cavity with that left by the enucleation of the left lateral lobe, and abundant room is furnished for the extraction of calculi. If the cystoscope has shown the calculus to be only a moderately large one, it is usually only necessary to dilate the vesical orifice with a uterine dilator in order to extract it with the forceps. If the calculus is too large to be thus withdrawn, a probe-pointed bistoury may be inserted, and the orifice enlarged by a cut through the vesical mucous membrane covering the left lateral cavity of the prostate.

I have followed the technic described above in five cases; in three cases removing one calculus, in one, two, and in another seven, with success in all. The ejaculatory bridge containing the ducts was not injured, no urethral nor vesical mucous membrane removed, and the perineal wound healed just as rapidly as after the simple prostatectomy; in one case, perineal leakage ceased after the ninth day. I have not found it necessary to close the divided urethra with sutures, but have simply provided the double urethral catheter drainage through the urethrotomy wound and the gauze packing for the lateral cavities as usual. The great advantage of perineal over suprapubic lithotomy is that the patient can be propped up in bed at once, and moved into a wheeled chair on the third or fourth day. The secret of success in these cases, is to flush the kidneys and to get the patients out of bed quickly, and this can not be done after the suprapubic operation with the same impunity and rapidity as in the perineal cases. In some cases *sectio alta* may be necessary, though an attempt to crush the stone through the perineal wound may be a decided one.

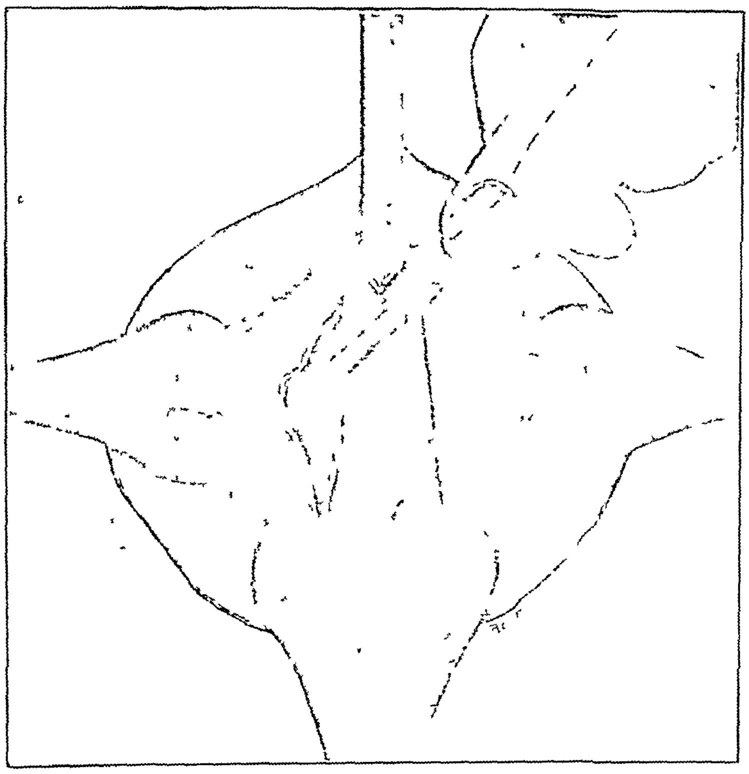

Fig. 8 — Stripping back the capsule with blunt dissector.

The following case shows that a very large calculus may be removed through a lateral cavity by the technic described above:

Patient.—S., male, aged 65.

Examination.—On cystoscopic examination a moderately enlarged prostate was found, complicated by a very large, rough vesical calculus.

Operation.—Perineal prostatectomy was performed by the usual technic, the urethra and "ejaculatory bridge" preserved and the moderately hypertrophied right, left and median lobes enucleated. The left lateral wall of the urethra was then divided longitudinally up to the vesical orifice, with scissors (Fig. 16). Large stone forceps were inserted into the bladder, and a calculus of great size caught. On withdrawing the forceps the calculus was found to be too large to pass through the dilated vesical orifice, but by making traction the vesical mucosa in front of the stone was drawn into the left lateral cavity, where it was divided with a scalpel, on the stone as a bobbin. After this, the calculus (Fig. 17) was easily extracted The divided vesical neck was then approximated with two catgut sutures, and the lateral wall of the urethra easily closed

Result.—The patient made an excellent recovery. The urine ceased coming through the perineum on the sixteenth day, no incontinence of urine followed; and normal micturition was established.

The stone, which is apparently oxalate of lime, has a very rough surface, and measures 4.5x3.5x3.5 cm.

PRELIMINARY TREATMENT.

This is of very great importance for successful results in these very delicate patients, and it is often wonderful how careful nursing will carry one over a crisis and get him finally into condition for operation, as shown by the following case:

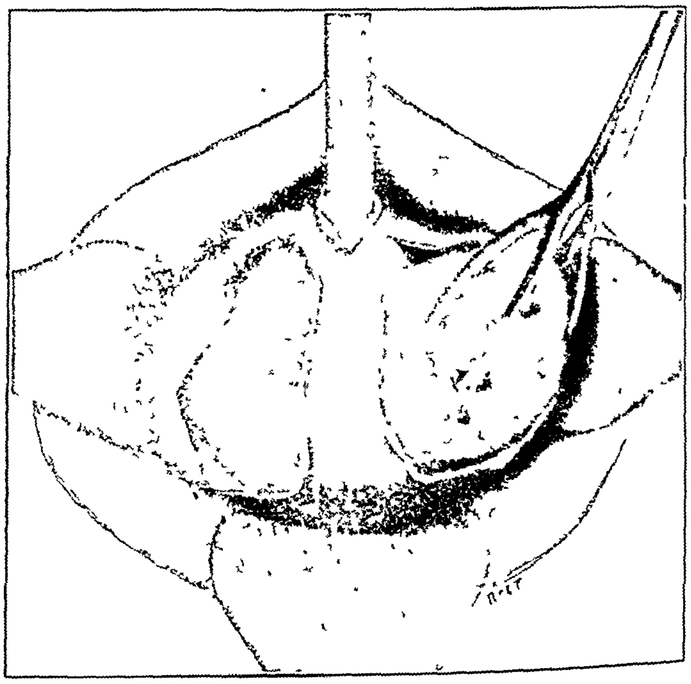

Fig. 9.—The enucleation of lateral lobes.

No. 576—D. C, aged 72, was admitted April 22, 1904, in a desperate condition.

History.—For five months he had been compelled to urinate every half hour, and ten days previously complete retention developed, but his physician was unable to catheterize him for 24 hours, when he found 1,500 c.c. of urine present. In a few days he had fever, nausea and a severe pain in left kidney. On entrance to the hospital he was emaciated, had fever, and showed evidences of uremia. His bladder was greatly distended and the left kidney was enlarged and *tender*. After two or three days be became desperately uremic.

Preliminary Treatment.—A rubber catheter was fastened in the urethra, and he was given submammary infusions and salt solution by rectum. Forced liquid diet was given for several days.

Result.—Under this treatment he gradually became rational, uremia disappeared, and finally, after six weeks of "internal hydrotherapy," perineal prostatectomy was performed under spinal anesthesia, cocain, gr. 1/3, being used. He was very little shocked by the operation, and made a satisfactory recovery. The fistula closed in 5 weeks, and examination six weeks after operation showed 20 c.c residual urine, urination free, bladder contracted by long drainage. and holding only 150 c.c, for which he will be treated by hydraulic dilatation. His general condition is excellent, and one would not think that only a few weeks previously he had been so desperately ill.

CYSTOSCOPY.

Cystoscopy is, I think, of very great importance, for it tells us the size, character and disposition of the prostatic enlargements in the bladder and thus indicates what we must look for at operation and the best means of attack. If the cystoscopy shows that the lateral portions are alone enlarged, there being no median lobe nor even bar present, we know at once that after the lateral lobes have been enucleated, nothing further is necessary. When on the other hand a definite median lobe is shown by the cystoscope, we should not rest content until it has been removed by the usual technic or by the modifications described above. The cystoscope has also shown other conditions, such as calculi, and vesical tumors, when such were little to be expected from the symptoms. The important rôle played by diverticula of the bladder, and demonstrated by the cystoscope is shown by the following case:

Patient.—E. J. I., aged 60, had had complete retention of urine and used a catheter for several years. He saw a surgeon in another city, who passed a catheter, and told him that he was suffering from prostatic hypertrophy, for which vasectomy would be the appropriate treatment.

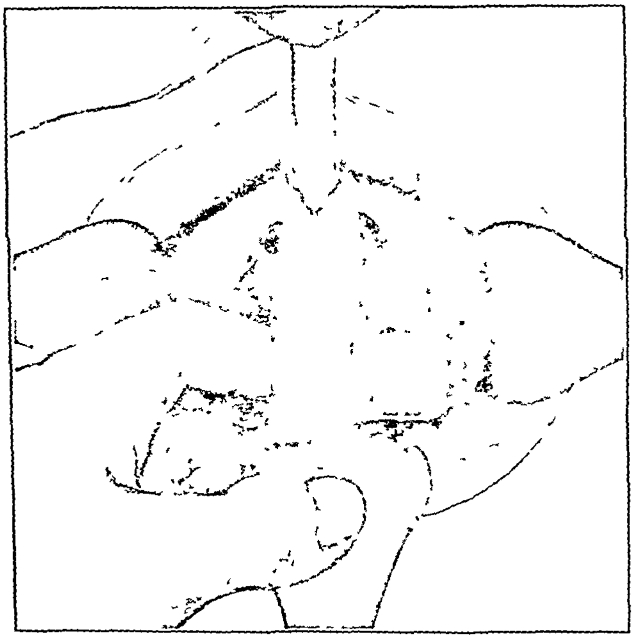

Fig 10.—Delivery of the middle lobe into left lateral cavity.

Examination.—On examination I found no prostatic enlargement, but the cystoscope showed that the obstruction to urination was due to two diverticula beneath the trigone, which was so elevated by them that it acted as an obstruction to the egress of urine through the prostatic orifice.

Treatment.—He was restored to voluntary urination by a suprapubic operation, in which the septa between the diverticula and bladder were divided and the cut edges sutured.

In another case, the cystoscope showed a small opening in the anterior wall of the bladder, which communicated with a very large diverticulum. The prostate was bilaterally enlarged, and 1,200 c.c. residual urine was present. Prostatectomy was performed, but as it seemed dangerous to leave the diverticulum I made a suprapubic incision, exposed the anterior wall of the bladder, found that the diverticulum had a neck like a gourd and extended backward beneath the peritoneum, and along the rectum, and contained about 500 c.c. of fluid. After division of its neck at the bladder wall the diverticular sac was easily extirpated, and the vesical opening closed like the stump of an appendix. The bladder was not opened in either procedure. There was no subsequent leakage and the patient is perfectly cured. Without the cystoscope, the diverticulum would not have been discovered, until at some late date when possibly occlusion of its orifice and perivesical abscess would have furnished an interesting autopsy. I might cite numerous instances showing the great importance of cystoscopy in every case before operation, where the condition permits. The cystoscopic views obtained of the different segments of the prostatic urethral margin I record in diagrams devised especially for this purpose as shown in Figure 18.[2]

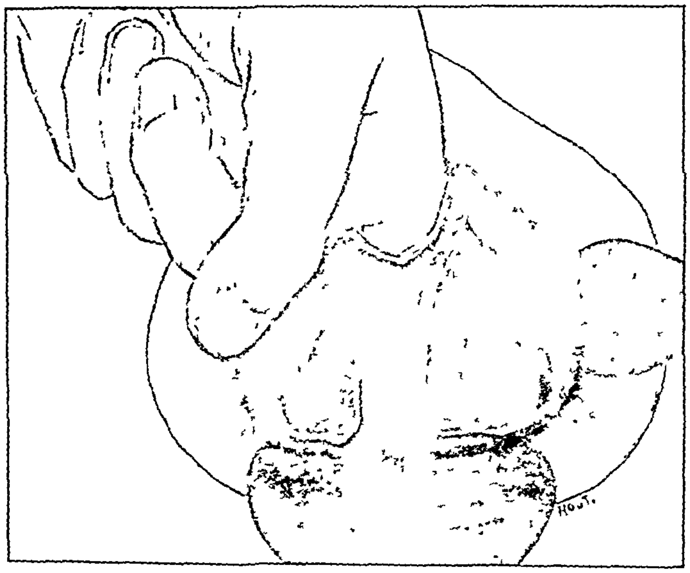

Fig 11.—The use of index finger to deliver a small median lobe into lateral cavity.

SPINAL ANESTHESIA.

The use of spinal cocainization has proved of very great value in those cases in which, on account of old age or renal disease, ether or chloroform would be dangerous. I now use one-third of a grain of dry sterile cocain, and allow it to dissolve in the spinal fluid which has been drawn into the barrel of a Luer all-glass syringe, which has been so successful in the hands of Goodfellow. In my cases, now numbering ten, there have been none of the unpleasant sequelæ which we used to have when an aqueous cocain solution was injected into the canal. In several instances there has been a very slight nausea and vomiting on the table, but this is all, and the anesthesia has been perfect. Two of my patients were over 80 years of age, and others were either very old or very weak. In one case, already mentioned when speaking of preliminary treatment, one kidney and possibly both were diseased, and the patient was very uremic. In several of these cases I would not have dared to give a general anesthetic, and I firmly believe that through the use of spinal anesthesia the radical removal of the prostate through the perineum has been made a very much safer procedure than it was when ether or chloroform was necessary, and that the Bottini operation has been robbed of the strongest argument in its favor, viz.: that it could be done under local cocain anesthesia. One-fourth of a grain, I believe, is sufficient to insure excellent results.

---

[2] The Use of the Cystoscope in Prostatic Hypertrophy, Bulletin of the Johns Hopkins Hospital, November, 1904.

AFTER-TREATMENT.

This has been so fully described in my previous article that I have little to add. As stated above, my guiding rules are:

1. To keep the kidneys very active, by means of water by mouth (from two to four quarts a day), and, if necessary, by subcutaneous infusions, or rectal injections of normal salt solution.

2. To get the patient up as soon as possible (propped up the second day, out of bed the fourth day, and walking as soon as possible).

3. Early removal of the gauze and tube drains. The former had best be removed on the second day and the tubes on the third or fourth day. The earlier the tubes are removed, the earlier the perineal fistula will close. Continuous irrigation of the bladder is now rarely continued longer than two or three days, sometimes only one. Since using it, however, I have not been troubled by the tubes becoming blocked by blood clots, as often happened before.

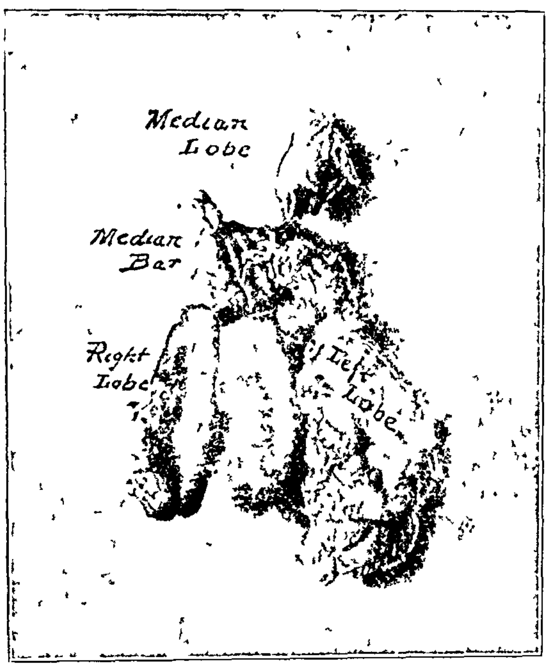

Fig 1.—Photograph, actual size Small pedunculated median lobe, small median bar. Two lateral lobes. Weight 15 gm.

4. Avoidance of instrumentation: The cases in which I used a retained urethral catheter, in the hope of facilitating the closure of the perineal fistula, have not proved the value of this procedure. In fact, in those cases in which the fistula closed in from 6 to 10 days, no catheter was inserted after the withdrawal of the perineal tubes. The wound is now allowed to close without additional packing after removal of the original gauze packs on the second or third day. I practically never pass sounds after operation. None of my 50 cases have shown any tendency to stricture formation, and a silver catheter will nearly always pass in without even detecting any roughness along the membranous urethra at the site of the urethrotomy. The use of the retained catheter, and dilatation by sounds are, I believe, the inciting causes of epididymitis. Cystitis and contracture of the bladder are the most important and common complaints with which we have to deal after the patient has been relieved of his prostatic obstruction. This is particularly true of patients who have suffered from severe interstitial cystitis or vesical calculus, or where the bladder has become contracted by a prolonged use of the retained catheter. In many of these cases the bladder may be distinctly enlarged by the patient voluntarily holding his urine as long as possible, and imbibing freely in water. It is often necessary to spend several weeks in forcibly distending the bladder by hydraulic pressure in order to restore that viscus to its normal size. In a paper on the subject[3] in 1898, I showed the simplicity and efficacy of this method, and in numerous cases recently I have demonstrated its necessity to obtain a functional cure; restoration to urination at normal intervals, after prostatectomy. The accompanying chart (Fig. 19), is the record of a case in which the largest amount of urine voided at a time was 60 c.c., the bladder on forced distention held only 80 c.c., and the interval between urination was one hour and ten minutes. The rapid improvement in vesical capacity, amount voided and the interval under "the hydraulic pressure treatment" is graphically shown in the chart.

RESULTS.

I have thus far (May, 1904) operated on 50 cases by this method. The ages of these patients were as follows:

Over 80 years	2	Between 60 and 65	13
Between 75 and 80	7	Between 55 and 60	6
Between 70 and 75	8	Between 50 and 55	2
Between 65 and 70	7	Under 50 years	5

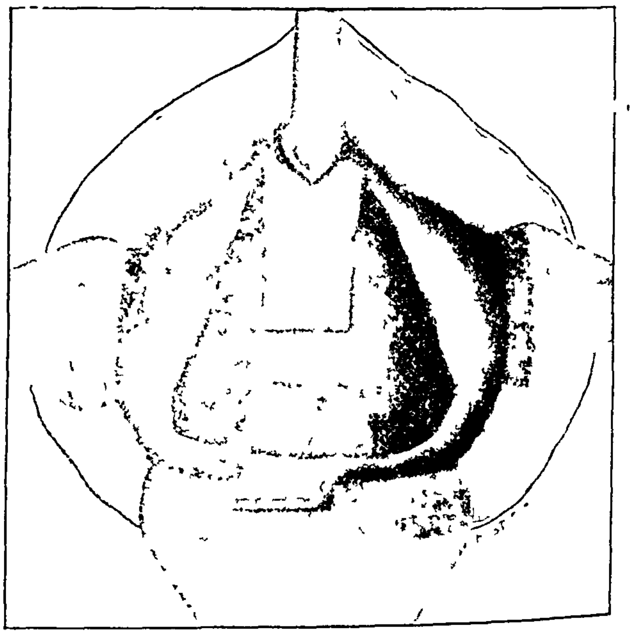

Fig. 13.—Division "ejaculatory bridge" suburethral enucleation of median bar.

MORTALITY.

There have been no deaths which, in my judgment, can be justly charged against the operation.

One man, aged 72, was in excellent condition two weeks after the operation, when, after an enema he died very suddenly and autopsy showed pulmonary embolism The second death occurred one month after the operation, in a patient aged 82 years, who did well for two weeks, but after that grew gradually weaker and died, apparently, as much from old age as from anything else The list of ages as given in the table shows at a glance the benignity of the operation, and the absence of operative deaths speak for its wider employment in severe cases.

In five cases a Bottini operation had been previously done (by me in three). One of these required prostatectomy on account of alarming hemorrhages from the intravesical prostatic enlargements. the other two, on account of difficulty of urination, due to persistence of prostatic obstruction. One case had incontinence of urine, which was not relieved by prostatectomy. The fifth case had been operated on by another surgeon without result, and was cured by prostatectomy.

---

[3] Bulletin of the Johns Hopkins Hospital, May, 1898

RELIEF OF OBSTRUCTION.

Eighteen cases had complete retention of urine and led catheter lives. Thirteen used the catheter, but were able to void some urine naturally; the frequency of using the catheter varied greatly. In 14 cases the patient did not use a catheter, although, in one case, the residual urine was 1,200 c.c. In 5 cases the urine escaped through suprapubic fistulæ. I have heard from all of these cases. None of them is using a catheter. The suprapubic fistulæ are all healed, and voluntary urination is present in all cases and but two or three complain that the stream is smaller than normal.

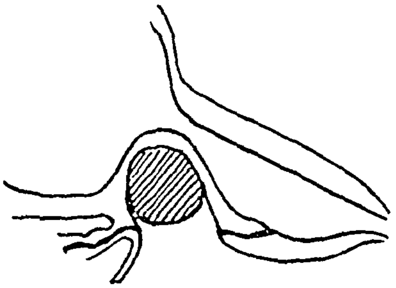

Fig 14.—Schematic longitudinal section of the urethra, showing the median enlargement enucleated beneath the urethra.

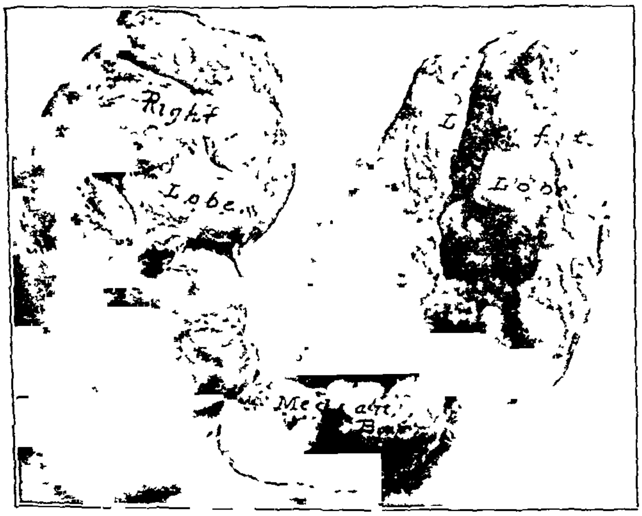

Fig 15.—Photograph of large lateral lobes and median bar removed by suburethral method

RESIDUAL URINE.

I know of no case that has more than 35 c.c. of residual urine. I have been able to examine about one-half of the cases and have found only once as much as that present, and in the majority there is no residuum. Those whom I have not seen have written me that they have every reason to believe that they can empty the bladder.

CAPACITY OF THE BLADDER.

The capacity of the bladder has much to do with the functional result.

In 10 of my cases the bladder was more or less markedly contracted before operation. In 3 cases calculi were present; the bladder held 50, 65 and 100 c.c., respectively; the first two were voiding urine very frequently and the third used the catheter every hour. After operation, all suffered from frequent urination. One remained for treatment and in one month his bladder capacity had been increased from 160 to 310 c.c., and the interval from one hour to three hours; residual urine, 8 c.c. One of the other cases, not treated, is able to void urine well and to empty his bladder, but the capacity is so small that he is compelled to urinate every half hour.

A very instructive case was that of a patient who came to the hospital very uremic, with a greatly distended bladder and pyonephrosis. Under continual catheterization, infusions and liquids he finally became strong enough for operation, but his bladder had contracted until it held only 30 c.c. Five weeks after operation he voided urine in a large stream, and there was only 20 c.c. of residual urine present. The bladder, however, will not hold over 150 c.c. on forced distension, and the patient has to void urine every hour and a half.

Another case had a vesical capacity of only 210 c.c. after operation but in four weeks the bladder was enlarged by twice daily forcible hydraulic dilatations up to 460 c.c., and 19 months after operation he voided urine every six to eight hours.

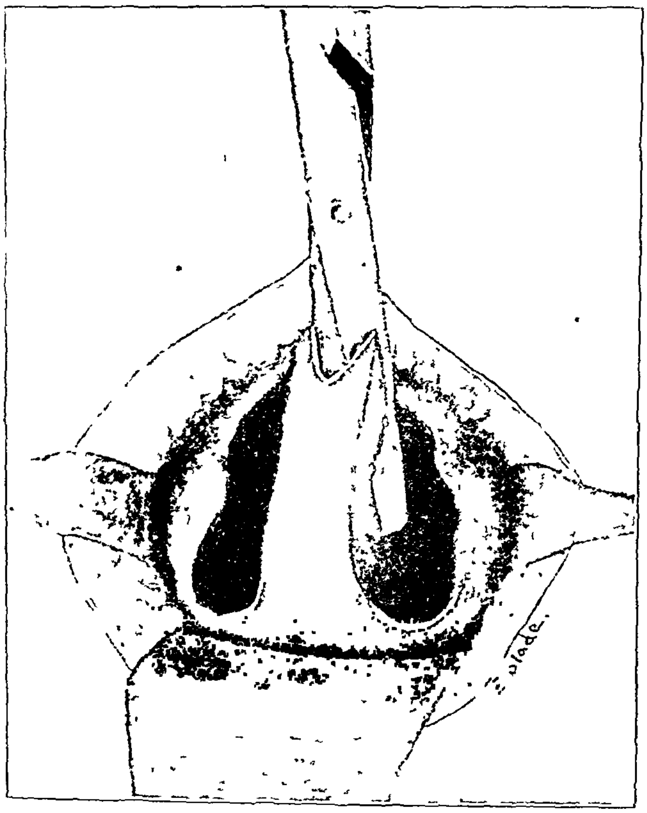

Fig. 16.—Division of lateral wall of urethra to allow extraction of large calculus through left lateral cavity.

I am convinced that several of my patients who now report frequency of urination could be restored to a normal interval by the dilatation treatment. This generally should not be begun until 5 or 6 weeks after the operation, when the fistula is firmly closed. Considerable pressure must be used, and it is necessary for the patient to endure a good deal of pain in order to accomplish results.

PRESERVATION OF SEXUAL POWERS.

I have tried hard to find out the exact status of the patients' *puissance* before and since the operation. This is a delicate question always, and one about which personal testimony is very likely to be slightly untrust-

INTRANASAL TREATMENT.

If we are not going to operate on our patient we must endeavor to maintain free drainage in the nose and not permit him to pass altogether from our observation. There is no doubt that in some cases the more aggravated symptoms are relieved and the state of the patient becomes more satisfactory when the intranasal condition is carefully attended to. If nasal polypi are thoroughly removed along with the anterior end of the middle turbinated bone, and the anterior ethmoidal cells opened into, better drainage may be established and the outflow of secretion rendered more easy. We have probably all seen cases in which the carrying out of this procedure has made the patient's condition more comfortable. In what proportion of cases a cure, as has been alleged, may result from intranasal treatment of this kind, is a matter which might form an interesting point for discussion. I am of the opinion that the number of such cases must be very small because both the anatomic configuration of the sinus and the pathologic changes which occur in its lining membrane in chronic suppuration militate against the chance of a cure merely from better drainage. It is necessary to bear in mind that the intranasal treatment outlined above should be carried out as a preliminary to an external operation on the sinus. Hajek,[6] however, takes a more favorable view of intranasal treatment; out of twenty-seven cases of chronic suppuration treated by intranasal methods, nine were completely cured; in eleven a mucopurulent secretion remained, while in seven no improvement was effected. In all of them, with three exceptions, the headaches disappeared. There were thus nine cases healed, while in eighteen the discharge continued. If, however, freer drainage from the sinus can be established in this way, it is possible that the risk of serious intracranial complications arising may be lessened.

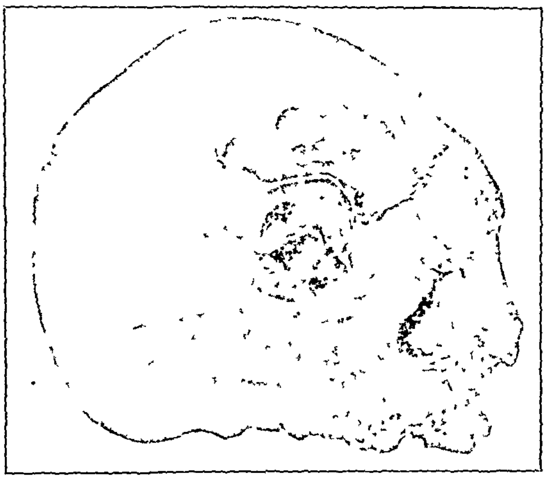

Fig. 3.—A large anterior ethmoidal cell is seen invading the orbital plate of the frontal bone and lying below the frontal sinus.

OPERATIVE PROCEDURES.

Having decided on operation, what procedure are we to adopt? Notwithstanding the numerous operations and their various modifications that have been described, many of which are associated with the names of different surgeons, there are only two main principles involved. First, the sinus is opened and drained into the nose, but its cavity is preserved; or secondly, the sinus is obliterated by the removal of one or more of its bony walls, so that there is no longer a cavity to deal with. If the first principle is adopted whatever be the precise mode of procedure, we still have a sinus remaining, which may subsequently become the seat of fresh infection. Little or no disfigurement follows this method of operating. If, however, we carry out the second principle and obliterate the sinus, we remove all possibility of further suppuration in this locality. At the same time by doing this we encounter a drawback, viz., a varying amount of disfigurement, which in this region of the body is one of no small moment and which sometimes, indeed, assumes very considerable proportions. The questions, therefore, which have to be considered are, what cases, if any, are suitable for treatment by preserving the sinus, and secondly, how may we best obliterate the cavity and at the same time produce the minimum of disfigurement. Again, can any method be adopted by which we may combine all the advantages associated with each of these procedures and at the same time eliminate their defects? These are the main points to which I would ask your consideration in this paper.

PRESERVATION OF THE SINUS.

The Ogston-Luc Operation.—It is quite unnecessary to present you with a detailed description of the operation so widely known under this title. Suffice it to say that it consists in opening the frontal sinus through its anterior wall, the size of the opening being relative to the dimensions of the cavity, in careful curetting of its interior and in establishing a large communication between the sinus and the nose, at the same time destroying the anterior ethmoidal cells in the region of the nasofrontal duct. Drainage into the nose is insured by the introduction of a strip of gauze through the nasofrontal aperture and the operation is completed by immediate suture of the skin incision.

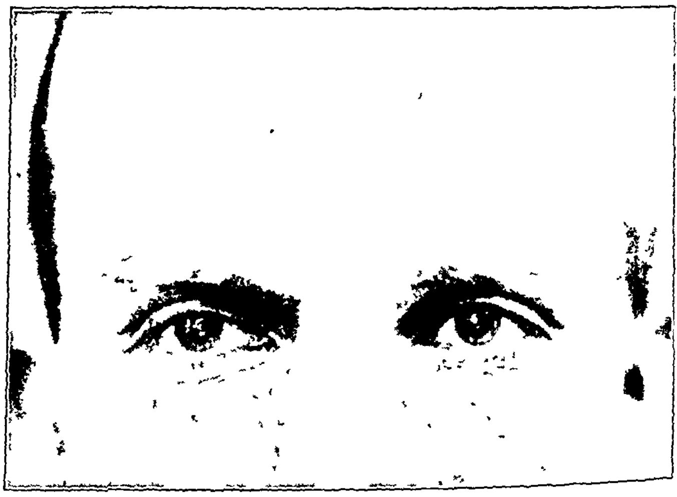

Fig. 4.—Patient, young man, after opening and draining left frontal sinus. (Ogston-Luc.)

Probably no operation, or a slight modification of it, has been more generally accepted and performed on the frontal sinus, yet more extended experience and a careful consideration of the results obtained from it go to show that the class of cases which is really suitable for this procedure appears to be a comparatively small one. This is due mainly to *anatomic* causes. If we consider the variations in the configuration of the frontal sinus, its variable extension vertically as well as outward toward the temporal region, and, not the least important, backward along the roof of the orbit, we can readily appreciate the difficulty of thoroughly inspecting the cavity through a somewhat limited opening in its anterior wall. If we bear in mind, further, that the frontal sinus is not always a simple chamber, but, on account of the existence in many instances of incomplete bony septa and partitions in its interior giving rise to one or more diverticula or recesses, it is difficult, and sometimes even impossible, to deal effectively with the whole cavity in this operation. These recesses are commonly met with in the external angle of the sinus and frequently in its horizontal or orbital portion. Both these situations are from their anatomic position very difficult of access. In consequence of this, pus and diseased mucous membrane may be overlooked and foci are left to cause fresh infection of the surface which has been curetted. Recesses may also exist in the vicinity of the septum between the two sinuses, and the non-recognition of these may cause the operation to fail.

---

[6] Nebenhöhlen der Nase, 2d ed., 03.

Figures 1 and 2 illustrate some of these points. Figure 1 is an example of a case in which a recess formed by a partition lying close to and parallel with the septum led to an unsuccessful result. The patient had been operated on by two surgeons by the Luc method, and I believe that on each occasion the narrow mesial recess was overlooked and proved to be the cause of subsequent reinfection of the whole sinus. It was not until the entire anterior wall was removed that its existence was determined. It was then found that in addition to this the cavity (right sinus) extended into the left supraorbital region This latter diverticulum had also doubtless been overlooked. Figure 2 represents another sinus which had been twice operated on without success by merely opening and draining the cavity. After removal of the whole anterior wall at a subsequent operation, a well-marked diverticulum was discovered in the external part of the horizontal portion of the cavity.

Fig. 5.—Patient, young man, after opening and draining left frontal sinus (Ogston Luc)

Another difficulty which may present itself and which, if not recognized, must obviously lead to the failure of the operation, is the existence of a communication between the two sinuses through the intervening septum. Such an intercommunication, although it may doubtless occur, is not a usual anatomic condition, and I have never observed the septum to be incomplete in the normal skull. As the result of a pathologic process, however, the communication is sometimes found in cases of chronic suppuration and the opposite sinus becomes infected through it. It may not be easy to recognize the existence of such a communication through the limited opening which is made in the Luc operation, consequently the opposite sinus continues to discharge its purulent contents into the cavity which one has attempted to render aseptic.

There is still another point which calls for attention, since it may prove a source of weakness in this method of operating, and that is the difficulty of gaining sufficient access to the anterior ethmoidal cells. In a proportion of cases one or more of these cells extends outward into the orbital roof beneath the floor of the frontal sinus. An example of this is seen in Figure 3. Under these circumstances considerable dissection not only of the anterior wall, but also of the floor of the sinus is necessary before these cells can be recognized. Suppuration in the ethmoidal cells may be concomitant of chronic suppuration in the frontal sinus. Consequently, in seeking to establish a free communication between the sinus and the nose, an attempt must be made to destroy or remove the diseased ethmoidal air spaces which may otherwise prove a source of reinfection. As we shall see later the importance of dealing with these, has led Killian to resect the ascending process of the superior maxilla and thus gain more ready access to them.

ASSOCIATION OF FRONTAL AND ETHMOIDAL SUPPURATION.

It will not be out of place at this stage to examine some of the published records bearing on the association of frontal and ethmoidal suppuration, and learn how frequently the two conditions coexist. When we come to study such figures as I have been able to obtain, relative to this point, we find that the experience of surgeons varies. Thus Jansen[7] in ten instances, Röpke[8] in thirty-seven, Killian[9] in sixteen and Luc[10] in four instances found the ethmoidal cells affected along with the frontal sinus. Walker Downie[11] in six cases has noted ethmoidal disease in five of them. On the other hand, Lermoyez[12] in thirty-six instances in which the frontal sinus was affected found only two with associated ethmoidal dis-

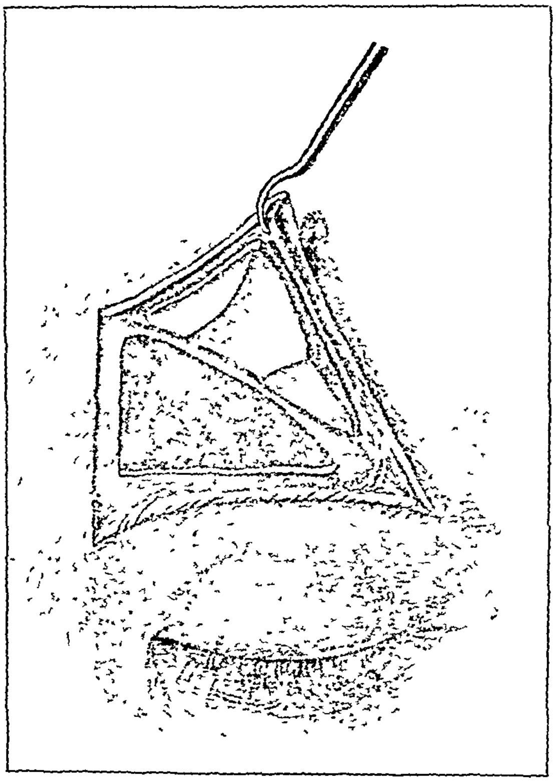

Fig 6.—Osteoplastic operation on frontal sinus Bone flap recommended by Hajek

ease; while Herbert Tilley[13] in twenty-five diseased frontal sinuses has noted six with ethmoidal suppuration. Milligan[14] has described in seventeen instances affection of the ethmoidal cells in nine, while of nineteen diseased frontal sinuses observed by myself the ethmoidal cells were also affected in eleven. In Wertheim's[15] postmortem observations the ethmoidal cells were found affected in seven out of twelve cases.

[10] Ann des Mal de l'Oreille, December, 1902.

[11] Glasgow Medical Journal, March, 1899

[12] Ann des Mal de l'Oreille, November, 1902

We find on adding these figures together that in 172 instances in which chronic suppuration of the frontal sinus existed the ethmoidal cells were implicated in 107—i. e., 62 per cent. In other words, in 40 per cent. or less than half of the total number of cases of chronic frontal sinus suppuration, the ethmoidal cells were healthy, a larger proportion than perhaps is generally believed. It is difficult, however, to assign a cause for the great disproportion observed between the figures recorded by such observers as Jansen, Röpke, Killian and Luc on the one hand and those of Lermoyez and Tilley on the other.

RESULTS OF THE LUC OPERATION.

We have thus far indicated the anatomic features which may conduce to the non-success of the Ogston-Luc operation. It is necessary, however, to consider whether clinical observations justify us in regarding this operative procedure in an unfavorable light. In endeavoring to collect reliable statistics on this point a difficulty was at once met with, namely, information as to the exact method adopted by each operator. The kind of drainage employed and the treatment of the skin flap must be regarded as factors of considerable moment in the success or non-success of the operation. It is obviously unfair to adversely criticise a recognized operative procedure when in some not unimportant details the operation has differed from the lines laid down by the originator of it. For this reason the figures which follow are not large, as I have limited myself to those cases which undoubtedly appear to have been treated by the Ogston-Luc method. They may possibly be considered by some to afford a too limited basis for reliable deductions to be drawn from them. In all there are fifty-five cases. Of these seventeen are reported by Lermoyez[12] in the paper already referred to, nine of which were cured and eight relapsed. Lambert Lack,[16] who does not take a favorable view of this operation, treated eleven cases by this method, not one of which was completely successful. In four of them headache and pain were relieved, but the discharge, although much diminished, continued. In five no relief was obtained. Two cases terminated fatally. Luc himself has been disappointed with his results, having found it necessary to operate again more than once in some of his cases. An analysis of ten cases which came under my own care shows that six were completely successful. The cavity in all of these did not exceed ordinary dimensions, and in two of them it was of specially small size. In two there was also associated ethmoidal suppuration. Of the four unsuccessful cases, one had associated ethmoidal disease, while two others had been already operated on twice; neither of these had ethmoidal suppuration.

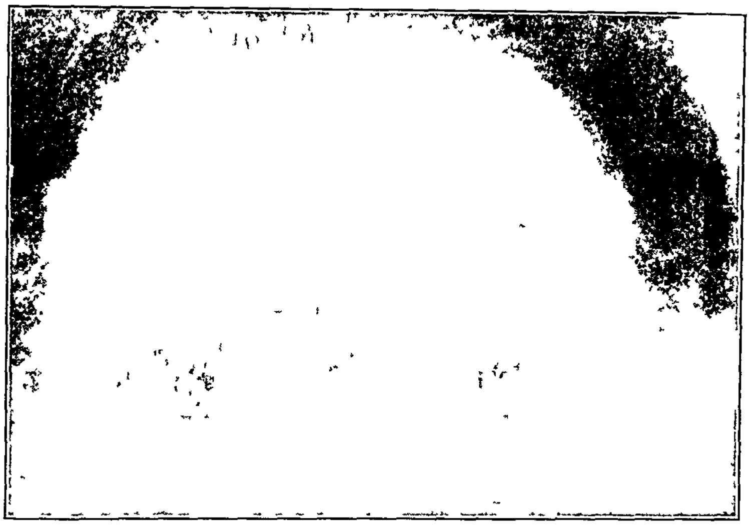

Fig. 7.—Patient, woman, two months after radical operation on large left frontal sinus (Killian method). A vertical incision was found necessary.

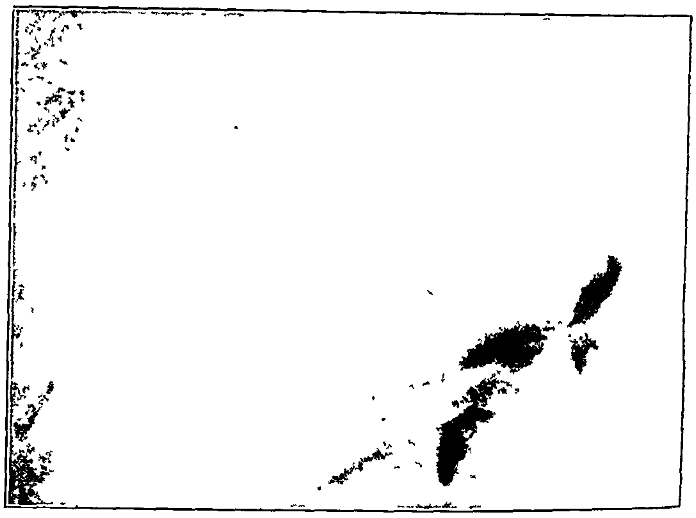

Fig. 8.—Profile view of patient, woman, three months after radical operation on large left frontal sinus. (Killian method.)

We find, however, that the operation has met with more success in some hands. Kuhnt[17] operated successfully in three cases, Grünwald[18] had six cases all successful, while Barbor and Furet[19] had no failures in eight cases. In summarizing these fifty-five cases we find that there are thirty-two cures and twenty-three failures, that is to say, a percentage of 58 successful operations. We shall see later how these results compare with the statistics of the obliteration method. Luc[10] himself now admits that the operation associated with his name has not given general satisfaction either in his own hands or in the hands of other operators. He considers it an ideal operation, however, only in certain cases, namely, when the dimensions of the sinus are limited, provided that the fronto-nasal canal is roomy, when the ethmoidal labyrinth is free from suppuration, and lastly, when the inflammation without being actually acute, has not persisted for more than a few months.

OPERATION FOR OBLITERATING THE SINUS. THE METHOD OF KUHNT.

Both anatomic and clinical evidence appear to be against the performance of an operation which does not permit of thorough inspection of the sinus and of the possibility of establishing a free communication with the nasal cavity by destroying the anterior ethmoidal cells should they also be diseased. In the majority of cases, therefore, we must seek for an alternative procedure by the carrying out of which the chances of failure and the risks of fatality are diminished. Experience goes to show that this is to be attained by obliterating the cavity of the sinus. In order to bring this about it is necessary to remove the whole of its anterior wall and also to a greater or less extent its floor. The removal of the floor is a valuable addition to the operation, I think, in those cases in which there is considerable extension of the sinus along the orbital roof. The removal of all the bone between the sinus and the soft tissues of the orbit is a guarantee that any ethmoidal cell extension into the roof of the orbit has been destroyed. Some operators, however, consider the removal of the osseous floor unnecessary. By this radical procedure we are able to thoroughly inspect the whole interior of the cavity, however large it may be, and no recesses can escape our observation. Further, the septum between the two cavities may be examined, and, as I have already said, the presence of ethmoidal cell extension into the orbital roof will thus not be overlooked. By this means also easier access is obtained to the ostium frontale and the diseased ethmoidal labyrinth may be more freely dealt with. Finally, we have the satisfaction of knowing that there is no longer a frontal sinus in which to fear recurrence of suppuration. In other words, therefore, if an operation of this kind, or some slight modification of it, such as the individual operator may think fit to apply, be performed, we eliminate all the defects and weaknesses of the less radical procedure.

[18] Die Naseneiterungen.

[19] Ann. des Malad. de l'Oreille, June, 1899.

If we now consider the curative results from the more radical methods, that is to say, in those cases in which the cavity of the sinus is obliterated, we find that the figures compare very favorably with those obtained after the Luc operation. My statistics are based on the results obtained in sixty-seven cases. Kuhnt has reported ten successes in ten cases operated on, and Röpke[8] was successful in all of his twenty-five cases. Lermoyez[12] had eleven cures in eleven cases of chronic fontal sinus suppuration; five of these had been operated on by the Ogston-Luc method, but had had recurrence of suppuration in the cavity. Lambert Lack[16] operated successfully in nine cases, and expresses the opinion that this method of dealing with the sinus is the most reliable. Hajek[6] obtained eight cures in nine cases, and Herbert Tilley[13] has recently published three cases, in all of which ethmoidal suppuration was present, and in which an excellent result was obtained. Of the sixty-seven cases here referred to a cure was effected in all but one, thus showing a very marked difference in the results as compared with the percentage of cures by the previous method. These figures are striking and though the total number of cases recorded here is not large, yet collectively they furnish sufficient evidence as to the respective merits of the two operations, so far, at any rate, as regards the cure of the condition. The question of comparative cosmetic results will be discussed later.

POSTOPERATIVE MORTALITY.

The comparison of the relative value of the two methods of operating is not complete, however, without consideration of the fatalities which have occurred after operative interference. Probably there are few surgeons, experienced in dealing with this class of cases, who have not had the misfortune either to lose a patient themselves, or to see a fatal result occur in the practice of one of their colleagues. A very considerable number of deaths have followed operation on the frontal sinus, and on that account we must necessarily regard it as one of the major operations in surgery. It is impossible to state with any degree of certainty how many fatalities have occurred, as there must be many cases which remain unrecorded. I have succeeded in collecting twenty-four, in which death followed operation on the frontal sinus. Of these sixteen have already been published, while I have information regarding eight others. Possibly others have been published, but I have not been able to obtain access to the literature dealing with them. The fatalities have been recorded by Luc,[20] Lermoyez,[12] Tilley,[21] Lack,[16] Rudloff,[22] Jaques,[23] Knapp,[24] Gibson,[25] Thiele,[26] Bryan and Gruening.[27] It is possible that in the cases reported by the two last mentioned observers the infection may have spread to the intracranial structures from the ethmoid cells, which were affected along with the frontal sinus.

The clinical picture presented by the majority of these cases is very similar. The infection which finally leads to the fatal result occurs, I think, at or within two or three days of the operation. The diploë of the frontal bone is invaded by the organisms and an osteomyelitis is in the first place set up. The infection spreads thence, on the one hand, through the outer table of the bone, giving rise to subperiosteal abscesses beneath the scalp; on the other hand it passes inward and may subsequently give rise to extradural or subdural abscess, general meningitis or cerebral abscess, the patient succumbing to one or more of these conditions, or to a general septicemia or pyemia after a varying number of weeks or months. Once an osteomyelitis of the frontal bone has become established, the prospect of cure by surgical interference is apparently hopeless. It commences insidiously and before the general symptoms and local signs are such as to permit of an exact diagnosis being arrived at the disease in the bone has made considerable progress. Even the most active treatment and apparently thorough removal of the bone in the neighborhood of the sinus fails to stem the slow but steady advance of the inflammatory process. In a case of this nature occurring under my own care no untoward symptoms supervened until the tenth day after the operation, when the temperature, which was previously normal, suddenly rose and some edema of the scalp was visible above the limits of the sinus. Subperiosteal and extradural abscesses formed and in spite of extensive removal of the frontal bone the patient finally died from pyemia after three months' illness. In Tilley's[13] case also symptoms developed ten days after the operation on the sinus and death took place after a protracted illness lasting for nine months.

An analysis of the fatal cases affords instructive reading when considered from the point of view of the nature of the operation performed. Of the twenty-four fatal cases there are twenty-three in which I have information regarding the operative procedure adopted. Of these seventeen, or 74 per cent., occurred after opening and draining the sinus (Ogston-Luc). Further analysis of this number brings out the fact that in fifteen death followed a single operation, while in two, more than one operation had been performed owing to the failure of the first to effect a cure of the suppurative condition. Of the remaining six of which we have notes all proved fatal after an operation for obliteration of the sinus, i. e., 26

per cent.; in three of these, however, simple opening and draining had been previously performed without success, the more radical method having been a secondary procedure. It is evident, therefore, that a considerably larger proportion of fatalities have occurred after the Ogston-Luc operation than after the operation of obliteration. I think that the question of a second operation on the same patient is one of some importance relative to the mortality. We naturally ask ourselves, Is the patient placed in a worse condition for further interference if the previous operation has proved a failure? Of the comparatively small number of fatalities quoted above, no fewer than five of the patients had been subjected to two or more operations by the Luc method. Three of these subsequently underwent the obliteration operation and died. I am, therefore, inclined to think that multiple operations exercise a detrimental effect, although we know of cases which have successfully undergone the simpler procedure and have been finally cured by more radical methods.

The presence of a discharging fistula in the forehead as the result of failure to cure the sinus suppuration must place the patient in a less satisfactory condition for further interference than if the skin remains unbroken. In the fatal case under my own care, to which I have already referred, there remained as the result of two unsuccessful Luc operations a permanent fistula in the line of the eyebrow discharging pus. At intervals there was considerable phlegmonous swelling of the scalp covering the lower part of the forehead, and it is possible that the bone forming the anterior wall of the sinus had already become the seat of septic infection. If we can satisfy ourselves that a patient in this condition is more prone to such fatal complications as we have enumerated, and if further operative measures are undertaken, then we have still another argument against the Ogston-Luc procedure. Not only does it give a greater number of failures, but it jeopardizes the non-successful case which will subsequently require more radical treatment.

In order to avoid the occurrence of such fatalities it is very necessary to try and determine when and how the infection takes place which leads to the spread of the septic process. A careful study of failures in the past should be the stepping-stone to future success.

I am of the opinion that in those unfortunate cases in which death results the inflammatory condition is lit up during the operation. The granulation tissue in the sinus which has hitherto formed a barrier to the invasion of the organism is broken down, and thus a path is opened which readily admits of their further spread in the frontal bone. I am now in the habit of using small flushing spoons while removing the diseased mucous membrane, a constant stream of warm sterile saline or boracic acid solution thus constantly playing on the surface of the bone. In this way an attempt is made to remove all septic material at once from the wound and thus to lessen the risk of further spread. If the patient's head is at the same time kept dependent the lotion readily flows over the vertex, so that the eyes are not exposed to the risk of infection. When curetting of the sinus is not complete we have a state of affairs present which must necessarily increase the chance of a dangerous complication arising. Foci of septic material are left, which may readily contaminate the newly exposed bone in the neighborhood. It is possible, as Lack has suggested, that the organisms may invade the anterior osseous wall of the sinus and thence spread directly into the vertical portion of the frontal bone. The density of the bone forming the anterior wall of the sinus varies considerably and in some instances presents a markedly diploic appearance. In neither of Lack's fatal cases was the mucous membrane of the sinus curetted, yet an osteomyelitis of the frontal bone supervened and death followed from intracranial complications. Tilley blames defective drainage into the nose, coupled with complete closure of the skin incision, as causes of disaster in these cases. Most surgeons will probably agree with the necessity of establishing free drainage, a point which has from time to time been insisted on by the majority of writers on the subject. In two of the unpublished fatal cases the operator informs me that no sutures were placed in the skin incision. In one case he attributes the fatal result to defective nasal drainage; in the other, numerous ethmoidal cells extending into the orbital roof were overlooked and bone sepsis was thus set up.

Do statistics show that the mortality occurring after operation is less in the last two or three years than it was previously? Is a riper experience leading to uniformly better results? While I think we may certainly answer the second question in the affirmative, one must admit that of the twenty-four fatal cases which have formed a basis for my remarks, no fewer than nine have occurred during the last two years. It is not my intention to overestimate the grave risks which may attend operation on the frontal sinus, nor would I have it inferred that because any one procedure has been followed by a certain number of fatalities that consequently it must no longer be attempted in suitable cases. Further, unfortunate accidents of this nature should not lead us to decline to operate on our patients should they desire relief at our hands. On the contrary, our failures should stimulate us to better work, because there is no better school than the school of experience. They should be the means of insuring more certain success in the future and we should do all in our power to improve our operative technic and at the same time be careful to carry out the most rigid asepsis in its minutest detai

DISFIGUREMENT.

There is, however, another very important aspec this subject, and that is the question of disfigurem No operation on the frontal sinus can be undert without this point presenting itself, and it is mainly this reason that the subject has been so much deba Were it not for this important consideration, much has been published on the surgery of the frontal si would never have been written. If the surgeon is gi a free hand by his patient and is asked to effect a c regardless of disfigurement, there is no question that will prefer to obliterate the sinus entirely and thus m any further trouble impossible. It is only occasiona however, that the position of affairs is so satisfactory, question of age, sex and social relations as a rule play an important part. Consequently it is our duty to s to obtain the maximum amount of success with the mi mum of disfigurement. There is no doubt about the c metic advantages of the operation performed accordi to the method first practiced by Ogston-Luc. The pres ervation of the anterior wall of the sinus and the imme diate closure of the eyebrow incision may be followed by such excellent results that in the course of time it may be impossible to observe any difference between the two sides of the face. Figures 4 and 5 illustrate patients whom I have operated on by the Luc method. It is unfortunate that equally satisfactory curative results can not always be obtained by this procedure.

With the obliteration of the sinus, on the other hand.

and the necessary removal of its anterior osseous wall, the contour of the forehead is to a certain extent destroyed. There consequently follows a greater or lesser degree of disfigurement, depending more on the antero-posterior depth of the cavity than on its superficial extent. The deeper the sinus the greater is the amount of the sinking in of the overlying soft tissues, and consequently the more pronounced is the subsequent depression. There is, however, undoubtedly considerable difference to be observed in the results obtained, a difference depending partly on the natural contour of the forehead in different individuals, the depth of the sinus and undoubtedly also on the possibility of the surgeon being able to leave more of the bony floor in one case than in another. As regards the skin incisions, if made in the line of the eyebrows, or even when a vertical incision is employed in one of the natural hollows, they are practically invisible, so excellent is the healing in this vascular region.

It is sometimes advanced as an argument against interference with the osseous floor of the sinus that diplopia or double vision may be produced from interference with the pulley attachment of the superior oblique muscle. This complication undoubtedly occurs in some cases. In one case detachment of the pulley may be followed by temporary interference with vision; in another no such effect is produced. It does not, however, as a rule, appear to be more than a transitory complication, and we must not regard it in the light of a contraindication to radical treatment. My own experience would lead me rather to regard detachment of the superior oblique muscle in a less serious light than some have done.

We have now discussed more or less thoroughly the arguments for and [illegible] out one or other of the two principles [illegible] early part of this paper. We naturally ask ourselves whether there is not some procedure which will give us all the advantages which attend the obliteration method of operating and which will, at the same time, give as nearly as possible the excellent cosmetic results obtained by the method associated with the name of Luc. Such an operation, if applicable to every case, would certainly be ideal and would terminate the many discussions which have been held on this subject.

OSTEOPLASTIC OPERATION.

By means of an osteoplastic operation an attempt has been made to overcome some of the difficulties, and [illegible]chönhorn, Czerny, Brieger and Winkler have practiced such a procedure by raising a bone flap from the anterior wall of the sinus. Hajek,[6] too, describes this method as the one which he has frequently adopted. Having previously defined the limits of the cavity by means of the x-rays, he proceeds to raise a triangular flap of bone from the anterior wall along with the superimposed soft parts as illustrated in Figure 6, taken from his work. Good inspection of the interior of the sinus is thus obtained and the small pockets and recesses can be dealt with. In order to gain access to and deal with the anterior ethmoidal cells, he has found it necessary to partially resect the nasal process of the frontal bone, and he finally completes the operation by introducing a large drainage tube into the nose. The bone flap with its superficial covering is replaced and the drainage tube is worn for a period varying from six to twelve weeks.

In a sinus treated in this manner the healing process is necessarily slow, considerable time being required before the new epithelium completely covers the interior of the cavity. The cosmetic results are good, but as the sinus is not obliterated there still remains the possibility of reinfection. Hajek does not give any detailed account of his results, but merely states that since he adopted this method of operating they have been better. He carefully guards against making any definite pronouncement regarding the value of the procedure or as to the duration of the cure after osteoplastic resection. In two of his cases operated on in this way and treated for some months, recurrence of suppuration took place eight and nine months respectively after the operation.

KILLIAN'S OPERATION.

There still remains for our consideration another procedure which, although first described in 1895,[28] has only recently come more prominently before our notice.[9] I refer to the operation which is associated with the name of Gustave Killian of Freiburg. In the author's opinion it fulfills the two main requirements in these cases more than any other method does, namely, the radical treatment of the disease with a minimum of disfigurement. Satisfied on these points himself, Killian is prepared to recommend and carry out treatment even in cases of suppuration where there is no discomfort experienced by the patient beyond the presence of slight nasal discharge. Should a more general and extended experience prove equally satisfactory, it is possible that in the "Killian operation" we have at last obtained a method of dealing with chronic frontal sinus suppuration in large and complicated cavities, which may be regarded as the method par excellence.

The whole sinus with its recesses and partitions is thoroughly inspected and the cavity is almost completely obliterated by the resection of its anterior and inferior bony walls. Further, by the removal of the ascending or frontal process of the superior maxilla, excellent access is obtained to the ethmoidal cells and a large opening of communication is thus made between the frontal sinus and the nasal cavity, so that good drainage through the nose can be established. In order to reduce to a minimum the deformity which may follow so extensive a dissection, the supraorbital bony margin is preserved as a bridge between the gap formed by the removal of the anterior sinus wall on the one hand and the floor on the other.

The results of this procedure have apparently proved eminently satisfactory both as regards the cure of the condition and the final cosmetic appearances. This has been the case not only in Killian's own hands, but also in the hands of others who have employed it. Thus we find that of twelve cases operated on in this way by him all, with but one exception, healed satisfactorily. The failure was due to the fact that the opposite sinus discharged through an aperture in the septum and so reinfected the area of operation. After this had been attended to a cure resulted, so that we may regard all the twelve cases as successful. Luc,[10] who has of late adopted this method of operating, informs me that of ten cases treated in this way nine were cured. In the tenth a fistula remained at the inner end of the scar, which he was unable to close owing to the patient being obliged to leave Paris. Thiele[29] reports six cases; in four a cure was obtained after one operation; in one, owing to failure in removing a part of the floor of the sinus and a pocket being thus left, a second operation was necessary, but at the time of writing sufficient time had not elapsed to admit of his recording it as a satisfactory result. In the remaining case death occurred apparently from meningitis four days after the operation. This case is included among the deaths already referred to. Siebenmann[29] has been thoroughly satisfied with the results which he has obtained by this method. In a case operated on by myself a few months ago an excellent result has been obtained. Of the twenty-nine cases above specified in which Killian's method was practiced, twenty-six were cured, or 83 per cent.

---

[28] Münch. med. Woch., No. 28, 1895.

The cosmetic results have also proved to be very encouraging. By leaving the supraorbital margin, the contour of the eyebrow is preserved and the depression which attends complete removal of the anterior and inferior walls of the sinus is undoubtedly minimized. Killian considers that there is less disfigurement after the removal of both the anterior and inferior walls than when the anterior only is resected. The orbital tissues take a considerable share in the filling up of the sinus area, so that the sinking in of the soft parts covering the vertical portion of the sinus is thereby reduced. One can not fail to be struck while carrying out the operation, both in the living and on the cadaver, with the ready manner in which the orbital fat rises up into the horizontal part of the cavity on removal of the bony floor of the sinus.

If the cavity is a deep one it is impossible to avoid some degree of flattening above the supraorbital margin; in order to diminish this as far as possible it is advisable to bevel the cut edge of the anterior wall at the upper margin of the sinus. In some cases where the sinus is deep and the septum between the two cavities is consequently prominent, the scalp may not fall satisfactorily against the posterior osseous wall of the sinus, so that a small cavity may persist in this situation. When the operation is performed on both frontal sinuses Killian advises the removal of the intervening septum on the ground that the depression which follows presents a more uniform appearance than when the septal ridge is preserved. Both Luc and Thiele comment favorably on the cosmetic results in their cases. Figures 7 and 8 represent a patient as seen three months after operation and the disfigurement is not marked. The removal of the ascending process of the superior maxilla does not lead to deformity. It has been urged against the Killian method that the incision carried downward on to the face is a disadvantage, but the skin wound there, like a vertical incision on the forehead which is sometimes practiced in frontal sinus operations, heals so readily that no appreciable scar is left.

The remarks which we have already made regarding the occurrence of diplopia apply equally in this connection. It may occur as a temporary drawback, but I am inclined to the opinion that there is an exaggerated fear regarding the production of this complication. Killian met with slight transient iritis in three of his cases, but by the prophylactic use of atropin this can be avoided. I have never met with this complication after extensive operations on the sinus. Great care, however, should be taken to handle the eye as little as possible and to avoid any undue pressure on it. The operation no doubt exposes the eye to the risk of injury and is more delicate to execute, is more laborious, and also occupies a longer time, but if better cosmetic results and a permanent cure can be obtained by it, such disadvantages must not be regarded as contraindications.

If exception is to be taken to any one point in the procedure, it seems to me that it lies in the fact that the cavity is not completely obliterated. A space remains behind the inner end of the bridge which continues to secrete and discharge a certain quantity of pus until a new lining membrane growing upward from the nasal cavity has completely covered the granulations. It is true that this cavity is merely a diverticulum of the nasal chamber and is accessible from it, but it prolongs the healing process, and two, three or more months may elapse before that is completed. Luc pays considerable attention to the after-treatment of these cases. The crusts which form in the frontonasal region are removed daily and a tampon of wool soaked in peroxid of hydrogen or in a weak iodin solution is carried upward into the cavity which is left. He lays considerable stress on the necessity of keeping the scalp in close apposition with the posterior wall of the sinus by means of a firm bandage maintained for a considerable period of time, a procedure which I would certainly indorse. It is very necessary that this apposition of surfaces should be accurate, so that the upper part of the cavity may be completely obliterated.

GENERAL CONCLUSIONS.

Certain general conclusions may be drawn from a study of this subject. In the first place it will be admitted, I think, that there is no single method of procedure applicable to all cases of chronic suppuration in the frontal sinus. When the sinus is a small one and we feel confident that we have thoroughly inspected it through the aperture made in the anterior wall, and when no ethmoidal disease coexists, simple opening and draining by the Ogston-Luc method may prove satisfactory. In these cases it is very necessary to insure a permanent communication between the sinus and the nose. On the other hand, we may prefer to obliterate such a cavity without incurring the risk of much disfigurement. In every other class of cases I would recommend and practice obliteration of the sinus.

The whole cavity may thus be thoroughly inspected and its recesses and bony partitions dealt with; better access to the ethmoidal cells may at the same time be obtained and a large communication made with the nose by resecting the frontal process of the superior maxilla. If the sinus is shallow and the supraorbital region is not prominent, it is unnecessary to preserve the bridge of bone. If more extended experience will show that the operation suggested by Killian provides satisfactory curative results with less disfigurement than is associated with other radical methods, then we probably have at our command an operative procedure which will take the first place. Whatever be the exact radical procedure adopted, there is no doubt of the value of removing the ascending process of the superior maxilla in order to gain better access to the ethmoid labyrinth and nasal cavity.

I am fully aware of the fact that this paper can not be regarded as a complete exposition of the subject. There are some points which have only been briefly touched on, and there are others which have not been considered at all. I have endeavored to place before you the broad principles which should guide us in dealing with these important and often troublesome cases. Questions of detail depend to some extent on individual operators and are points which may be conveniently taken up in the subsequent discussion.

It seems to me that the time has come when a collective investigation into the results of surgical interference on the frontal sinus and possibly also on the antrum might prove of the greatest value. Lack of sufficient opportunity has hitherto prevented me from undertaking this, but if we could obtain a really accurate report of the chronicity of the cases, the number of sinuses affected, the surgical method employed in operating, the treatment of the wound and the results obtained as regards cure, relapse, the amount of disfigurement produced and a fatal issue, we would possess a valuable guide for our future work. The statistics which I have quoted here are of a somewhat fragmentary nature and are gathered from the work of a comparatively small number of men. Perhaps the time is not far distant when we may be the fortunate possessors of the information to which I refer. It should be the aim of all of us to so perfect our methods that we are able to operate on every patient with frontal sinus suppuration, confident that we will effect a cure with the minimum of disfigurement.

---

[29] Arch. f. Laryngol., vol. xv, 190

In conclusion I wish to acknowledge the valuable assistance which I have received from my friend, Mr. John Grieve, in the preparation of a number of my photographs, and to express my thanks to Prof. D. J. Cunningham of the University of Edinburgh for the opportunity kindly afforded me for dissection on the cadaver.

DEMENTIA PRÆCOX.*

F. X. DERCUM, M.D.

Professor of Nervous and Mental Diseases, Jefferson Medical College; Neurologist to the Philadelphia Hospital.

PHILADELPHIA.

In the writings of some of the earlier authors, notably Pinel, Spurzheim and Esquirol, we find that they recognized the affection now so widely known as dementia præcox. This recognition was, to be sure, vague and imperfect; the affection was naturally confounded with other dementias, paretic, organic and alcoholic and yet these early writers were aware that there was a form of idiocy which was not congenital, and which supervened only after the organism had attained a certain degree of development. Spurzheim, for instance, speaks of an "accidental idiocy," while Esquirol speaks of "accidental and acquired" idiocy; thus the latter says that there are children who are very well at birth, who increase in stature at the same time that their intelligence develops and who are very sensitive, lively, irritable, passionate and possessed of a brilliant imagination, a developed intelligence and an active spirit. This activity, not being in relation to the physical strength, these creatures use themselves up, they rapidly exhaust themselves, the intelligence becomes stationary, they acquire nothing more, the hopes to which have given rise vanish, while they finally pass into a terminal period of dementia. Subsequent writers recognized similar conditions, e. g., Rousseau and Moreau, though the former regarded primary dementia of the period of puberty as very rare, while the latter declares that such cases (early mental maturity and later idiocy) are very frequent. Morel,[1] under the title of "Hereditary Insanity, with Limited Intellectual Existence, Tendencies, Precocious and Innate to Disease, Transition to Idiotism, the most Irremediable, under the Influence of Certain Intercurrent Causes, etc.," describes cases which clearly belong to the hebephrenic or simple form of dementia præcox, and in commenting upon them, he says that a sudden immobilization of all of the faculties, *une démence précoce,* indicates that the young subjects have reached the termination of the intellectual lives of which they are capable. They live intellectually only up to a certain age, after which arrest takes place and they fall progressively into a state which he can only compare to idiocy. To Morel belongs the credit of having first made use of the expressive designation *démence précoce,* and it was Arnold Pick of Prague who first employed its Latin equivalent, *dementia præcox,* now so largely used. Pick described a number of cases clearly belonging to this group of affections.

It is not necessary to dwell here on the epoch-making studies of Kahlbaum, who first differentiated hebephrenia and catatonia (1863, 1874) from the great mass of demented cases, nor is it necessary to speak of Hecker's historical study of hebephrenia (1877). Time and the object of this paper also forbid comment on the writings of subsequent authors.

There is one author, however, whose name must be mentioned, for he has made the domain of dementia præcox peculiarly his own. His views, novel and striking, at one and the same time excite our admiration and challenge our criticism. It was Kraepelin who first gave to the term dementia præcox a broad interpretation. His point of view appears to have been reached by a process of gradual development. In the fifth edition of his Psychiatry, he still makes use of the term dementia præcox as designating a form of mental disease practically the equivalent of the hebephrenia of Hecker and Kahlbaum, and he limits the term to this designation. In this edition (the fifth) catatonia is still treated separately and not embraced under the heading of dementia præcox, and the like treatment is accorded to dementia paranoides. In the sixth edition, however, of his work, Kraepelin greatly expands the term dementia præcox; in fact, he gives it a new meaning. He no longer describes a specific form under this name, but applies it equally to hebephrenia, catatonia and dementia paranoides; in other words, these diseases are now treated by him as only so many different forms of one affection. It is difficult to speak in moderate terms of the value and importance of this brilliant generalization. It has served to greatly reduce the difficulty of study and classification, and even of prognosis. Furthermore, it has enabled us to give to certain *symptoms* a fundamental value and to others a value merely secondary—in other words, to properly co-ordinate related facts.

However, this change, and the present status of the subject, makes it imperative that certain important points should be considered. To begin, the name itself, dementia præcox, demands discussion. The term "dementia" implies of necessity a downward or degenerative process; in the psychiatric mind it is associated with the mass of hopeless terminal demented states which are met with in the asylums, and yet, as a matter of fact, it is known that a history of persistent or permanent mental loss by no means always obtains in dementia præcox. Every asylum will bear witness to the fact that cases of hebephrenia and catatonia do recover, while even a larger percentage of recoveries (among hebephrenics) is noted among the milder cases, whose condition does not demand asylum commitment, i. e., the extra-mural cases. While it is true that in the great majority a hopeless dementia is the final outcome, still Kraepelin himself admits a not small percentage of recoveries, 8 per cent. for hebephrenics and as high as 20 per cent. for catatonics—though he considers the possibility of recurrences.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

[1] Traité de Maladies Mentales, pp. 562 to 566.

If recovery takes place at all in dementia præcox, surely the term dementia is inappropriate; the objection to its use is not only scientific but ethical. Far better is it to employ a term such as *das Jugendirresein* of German writers,[2] a term the English equivalent of which is the insanity of youth, or better still, the insanity of adolescence. The term dementia præcox conveys, in its very sound, an unfavorable prognosis; not so with the term insanity of adolescence. This presupposes nothing as regards the future, and leaves the question of recovery to be determined by the course of the case; sentence is not pronounced on the patient at the time of the making of the diagnosis, but is charitably as well as scientifically withheld. Finally, the fact that youthful patients are also liable to suffer from the various infectious or toxic psychoses and to manic-depressive insanity can offer no objection to confining the term insanity of adolescence to the field occupied by hebephrenia, catatonia and dementia paranoides. Neither the infectious and toxic insanities nor the manic-depressive form are peculiar to youth. Further they already have distinguishing appellations.

Another point of importance is the use of the term hebephrenia. Hebephrenia implies of necessity a disease of puberty, and while there can be no doubt that the time at, near or about this epoch is the most favorable period for the development of this affection, it is equally well established that hebephrenia may occur much later. Furthermore, the term hebephrenia is apt to convey to the mind of the student that there are special and distinguishing features presented by its history and symptoms, whereas it is in reality the simple expression of dementia præcox, and it should be so designated. It is certainly far less confusing to the mind of the student to speak of the simple form of dementia præcox or insanity of adolescence than to speak of hebephrenia. In fact, J. Rogues de Fursac, one of the French disciples of Kraepelin, has already adopted this term. Instead, therefore, of speaking of the different forms of dementia præcox as hebephrenia, catatonia and dementia paranoides, we would merely speak of the simple form, the catatonic form and the paranoid form. Terminology is often confusing, and whenever possible clearness should be aimed at.

Holding now clearly before our minds these three forms, let us briefly analyze their elements. In reading Hecker's historical paper on hebephrenia, one gleans three essential symptoms; first, an initial period of variable duration during which the patient is in a phase of depression; second, a period during which the depression fades and elements of expansion become manifest; third, and most important of all, a progressive dementia noticeable early and becoming gradually more and more marked; this is a clinical description which I need hardly point out accords closely with our experiences of to-day.

If we subject the symptom group of catatonia to a similar process of analysis, we find that there are present, as in hebephrenia, the same cardinal factors—the initial wave of depression, the subsequent wave of expansion, or mingled expansion and depression, and a progressive dementia, together with definite and characteristic motor symptoms which give to the disease its specific peculiarities and name, i. e., the fixed attitudes, the stereotypy, catatonia, automatism, automatic resistance, etc. When we turn our attention to dementia paranoides, and I now use the term in Kraepelin's original application—as employed in his fifth edition—we come to a group of cases in whom there is as before an initial wave of depression, a subsequent wave of expansion and progressive dementia, but added to which there are not now special motor phenomena, but special psychic phenomena in the shape of delusions, persecutory or expansive, which in their character—though unsystematized—suggest or simulate paranoia.

In studying the group of insanities of adolescence as a whole, certain other facts also become evident; first we learn, as was pointed out several years ago by Pickett, that the various forms tend to occur by preference at certain ages; that is, other things equal, cases of hebephrenia begin at a younger average age than do cases of catatonia; second, cases of catatonia begin at an earlier average age than cases of dementia paranoides, and thirdly, cases of dementia paranoides constitute the oldest group of all. That this generalization is not detailed in its application goes without saying. It is as are other scientific truths, general in its character, but is of the most decided significance. To some extent, the phenomena observed are in keeping with the facts of age, that is, the symptoms largely correspond to the degree of mental development to which the patient has attained at the time of the inception of the disease.

In the early, the hebephrenic or simple form, we have a wave of depression and a wave of exaltation, which is usually of a moderate altitude. It is unusual for the emotional wave to assume the depth or height seen in older cases. Sometimes, indeed, the depression and expansion are so slight that they are described by such terms as "mild depression," "mild hypochondriasis" or are merely characterized by a neurasthenoid group of symptoms. Indeed, the wave of expansion or exaltation may be so mild that its manifestations may be revealed only by physical elation, or boisterous and noisy conduct.

Again in hebephrenia the delusive beliefs are manifold and without attempt at definite arrangement; in other words, there are present the symptoms of moderate initial depression, moderate expansion with a simple dementia. When we turn our attention to catatonia we find that the phases of depression and expansion are somewhat more marked, while the psychic content of the delusions is somewhat higher—less childish or puerile on the whole—than in hebephrenia and a tendency to some arrangement of ideas, however loose, is frequently observed. In dementia paranoides, phases of depression and expansion are likewise marked, though the most prominent features now present are the delusions and hallucinations which both in their content and persistence suggest paranoia.

Let us now consider briefly the position of dementia paranoides. In his fifth edition, Kraepelin, to whom we owe this term, limits it to cases characterized by disconnected persecutory and expansive ideas, which rapidly pass into a persistent terminal confusion or dementia. In his sixth edition he made a decided change; this consisted in including under dementia paranoides the group of cases which he had formerly designated as the "phantastic form" of paranoia. The change was a very radical one, for it disposed at one blow of a large mass of cases universally regarded as belonging to paranoia. It includes almost the totality of the *délires systemtématisés* of French writers—the *délire chronique* of Magnan—and leaves nothing of paranoia proper except the form corresponding to Magnan's "insanity of the degenerates," or Kraepelin's *"combinirte Form."* In his fifth edition, Kraepelin depicted as phantastic paranoia, the form in which the delusions gradually withdraw themselves from the influence of actual perceptions, and are based more and more on hallucinations and independent invention; the disease presents the usual phases of depression, transformation and expansion. In his seventh edition, Kraepelin adheres to this radical substitution.

---

[2] Troemner and Ilberg.

I can not but feel that this change has been an unfortunate one, and that by it Kraepelin does violence to facts. It is certainly absurd to speak of a dementia as precocious which may begin as late as 40, 45, 50 or 55 years of age. Equally inapplicable is the term "Jugendirresein." In concluding his very excellent description of this form of paranoia in his fifth edition[3], Kraepelin says that the majority of the cases occur between 25 and 40 years of age; he adds that there are a group of cases which begin at a more advanced age—between the fiftieth and sixty-fifth year. In his description of the phantastic form of paranoia, in the sixth and seventh editions of his work, included now under dementia paranoides, this paragraph as to age is omitted. Why? Are the facts which were true in 1896 no longer true in 1899 or 1904? That they are still true will be admitted by every physician of asylum experience. Do such facts warrant the forcing of this group of cases into the frame of precocious dementia? That this group of cases really belongs under the head of paranoia we believe is established by the following: In the first place, it is impossible to sharply differentiate them from those to which Kraepelin has now limited the term—a group which, as we have already stated, corresponds to that designated at one time by Magnan as the insanity of the degenerate, and which was formerly designated by Kraepelin as the *"combinirte Form."* The latter constitute a group which is characterized by a very slow evolution of symptoms and by a very prolonged course, but in which the stages of depression, transformation and expansion are alike discernible. The cases are characterized by the fact that their delusions are based more or less largely on misinterpreted perceptions rather than on hallucinations, and that the delusions are perhaps better defined, better systematized and more firmly fixed than in the "phantastic form" or *délire chronique,* and yet these differences are only relative. They are, after all, only variations of degree and not of kind. Even if we take the point in regard to the absence of hallucinations in the *"combinirte Form"* as the standard of differentiation, we find that the moment we analyze it, it breaks down. Not only is it a fact that special sense hallucinations—hallucinations of hearing and of sight—do occur in some cases of this form, but my own observation has convinced me that while special sense hallucinations are relatively uncommon, general coenesthetic and psycho-motor hallucinations are by no means infrequent, and that the latter, as in the other forms of paranoia, form the foundation stone on which is based the mental attitude and the emotional tone of the patient. To define paranoia as a disease of the logical apparatus is a bizarre misstatement, which leaves out the intrinsic and fundamental features of the affection. That there is in all probability an underlying unity in all of the auto-degenerative psychoses which binds together all of the various forms of mental disease beginning with hebephrenia and ending in Magnan's paranoia (insanity of the degenerate, *"combinirte Form"*) is very probable. Perhaps there is an underlying unity of cause; indeed, it seems to me that this is probable. The mental picture presented is so varied by the elements of age and other factors that special clinical pictures are inevitable. If a term be devised (dementia præcox being abandoned) which would include all of these progressive degenerative changes under one head it would perhaps be right to consider them together and to treat of them as one disease. In such case, there would not only be included the phantastic paranoia, but the other form of the paranoia as well. I believe, however, that such a generalization as this would be scientifically and practically very disadvantageous, and would be as objectionable as is the present inclusion of the phantastic form of paranoia under dementia præcox.

We have in the solar spectrum seven colors, each color passing by a most gradual transition into another. Shall we, because it is impossible to draw hard and fast lines—because we can not say, for instance, where violet ends and blue begins, say that violet and blue are the same; or that green and yellow—most opposite in their reaction on the human sensorium—are the same because they pass by insensible transition one into the other? Surely nothing can be gained by wiping out well established lines of demarcation. Change does not always mean progress; it sometimes means error. Practical experience teaches us that no sharp differentiation can be drawn between the various forms of dementia præcox—hebephrenia, catatonia and dementia paranoides. Every now and then we meet with cases of hebephrenia in which passing motor phenomena, convulsions, transitory rigidity or stereotypy is noted, or again cases of dementia paranoides in which like features cause an approximation to catatonia. Similarly I believe that it is often difficult, if not impossible, to draw a differentiation between a dementia paranoides and a phantastic paranoia just as it is impossible always to make an absolute differentiation between the latter and the paranoia of Magnan, the "combinirte" form of Kraepelin.

DISCUSSION.

Dr. F. W. Langdon, Cincinnati, said that dementia præcox as a name, apparently, does not apply to a considerable number of these cases. When this condition develops at 30 or 40, or even at 50 years of age, and when it is not terminal dementia nor paretic dementia, nor post-organic dementia, they are classed as dementia præcox. If it can be shown that some of these patients had their original attack at adolescence and that what was looked on as a recovery has really been only a remission, then perhaps they are correctly called dementia præcox. Dr. Langdon considers that this condition is primary degenerative psychosis, which may be arrested for a time at various periods, and which, in most cases, eventually tends toward complete dementia. While no sharp lines of demarcation can be drawn in the psychoses, yet there must be some kind of demarcation for practical purposes, just as in the colors of the spectrum artificial lines must be drawn where the natural do not exist. Dr. Langdon thinks that while the term insanity of adolescence may be applicable to cases of dementia præcox, it does not clear up matters very much, because cases occur at 30, 40, or at 50 years of age, which can not be called insanity of adolescence unless it can be shown that they began at an earlier age. Experience seems to attach a significance to the term dementia præcox, though probably there is no reason why primary or idiopathic dementia would not be just as suitable.

Dr. F. X. Dercum stated that he believes that the older cases should not be classified with the younger ones. He believes that the original designation ought to stand and to stand unmodified; otherwise it loses a great deal of its clinical value. He does not believe that we ought to wipe out distinctions where they exist, just because the cases merge one into the other. The early cases are a distinct group by themselves; they are different from the adult cases of paranoia. It seems to him that it mars the picture, and certainly makes the term meaningless to include the adult cases of paranoia with those of dementia præcox. He thinks that it would be better to classify the juvenile cases under the term insanity of adolescence and leave off the term dementia præcox.

THE NATURE OF TRAUMATIC SCLEROSIS.*

ARTHUR CONKLIN BRUSH, M.D.
Neurologist to the Kings County, Brooklyn Eye and Ear, Williamsburg Hospitals, Home of St. Giles and Bushwick and East Brooklyn Dispensary.
BROOKLYN, NEW YORK CITY.

Though most of the confusion which once surrounded the results of trauma to the nervous system has been dispelled, so that we are able to recognize definitely most of the functional and organic diseases for which trauma is a competent producing cause, the nature of the condition in question is still open to investigation. The questions at issue at the present time seem to be, is this pathologic entity with an organic basis, is it only a grave type of hystero-neurasthenia, is it a distinct functional neurosis, or is it a type of true multiple sclerosis?

The evidence on which rests the claim for an organic basis for this condition dates back to the findings of Westphal, who, in 1878, described disseminated foci of sclerosis in the cerebrospinal axis as a result of trauma. Bramwell also described these lesions as secondary to minute hemorrhages. Sterling Kranthal, Dumenil, Petit and Edges confirmed these findings in their descriptions of degenerations of the columns of the cord, minute hemorrhages into its gray matter, and arterial sclerosis of both spinal and cerebral arteries as a result of trauma.

The evidence furnished by these pathologic findings is further supported by the results furnished by the experiments of Mendal, who fastened dogs to a rapidly revolving table and thus produced adhesions of the cerebral membranes, increase in the glia nuclei, vascular congestion and degenerative cell changes. Fustener, by continuing the experiment for a greater time, was able to produce besides these changes sclerosis of the posterior columns and optic nerves. Schmaus, by diffuse violence applied to the spine, was able to produce degenerations in the spinal neurons and vascular degenerations. His conclusions, as summed up by Knapp, are: that there is a distinct traumatic necrosis of nerve fibers; that more fibers die than can be recognized; that the fibers may be merely fatigued (fatal cases with no lesions and recoverable ones); that this fatigue of fibers may cause their death (gradually produced lesions), and that a gliosis ending in tumor formation may occur.

Since the time of these writers their findings have been so often confirmed that there *seems to* be no conflict of evidence as to the theory that trauma is a competent producing cause for these findings.

Our present knowledge of the results of diffuse violence to the cerebrospinal axis can be summed up as follows: That said violence can produce a condition known as concussion or commotion; that in this condition there may be localized hemorrhages, laceration contusion of nerve tissue, multiple minute hemorrhages or thrombi scattered throughout the cerebrospinal axis, general edema, distension and infiltration of the blood vessels; that from these lesions the following secondary changes may occur: The vascular hyperemia and infiltration of the vessel walls not only decreases the amount of *nutrient lymph supplied to the nerve* tissue, but also interferes with its return by a proliferation of the adventitia and a collection of débris and leucocytes in the perivascular spaces.

This then deprives the nerve cells of nutriment, and at the same time they are poisoned by waste products. Monti's observations show that the nerve cells die in a few hours when their nutrition is entirely cut off, and that defective nutrition causes the same changes after longer periods; the degenerative changes beginning in the distal parts of the cell and finally destroying the nucleus.

The effect of rupture of an axion is to cause swelling of its cell body, an eccentric position of nucleus, a disappearance of the chromaphilic elements, a loss of the striped appearance, and finally disintegration. In embolism and thrombosis the cells in the affected areas become edematous, the chromatin particles collect in the centers and finally disintegration occurs. In all *forms of injury to the nerve cells its dendrites* are first to degenerate, then its axon, and finally the cell body. The changes shown in the nucleus of these cells are a more deeply staining of the nucleus, which becomes vacuolated and finally small and angular. Coarse, granular changes are said to be characteristic of the chronic forms of degeneration, and depigmentation of sclerotic processes. The changes described in the neuroglia cells consist of swelling, an engorgement with granular detritis, and finally disintegration. The spider cells are said to resist the longest. There seems to be no conflict of evidence as to the theory that a nerve cell which has undergone degeneration is ever replaced, but we seem to have as yet no facts to show how far this process can be developed so as to forbid recovery.

The final results then of commotion or concussion of the cerebrospinal axis, in which the damage has been severe enough to forbid recovery would appear to be the production of areas of degeneration, areas of sclerosis and possibly arteriosclerosis, Bailey and Meyer considering the latter finding to be a coincidence.

Five cases of my own, which illustrate the various stages of the development of these lesions, have come to autopsy.

Case 1.—This case, showing the primary lesions, was *that* of a woman, aged 49, seen in the Kings County Hospital. Family and previous personal history, negative.

History.—Two weeks before admission she fell down a flight of stairs, received bruises about the body and limbs, and for a few hours suffered from shock. After one week she became unable to work.

Examination.—Examination showed the patient to be very stout and to lie with the limbs flexed. When made to stand, she slowly sank to the floor. Her speech was indistinct, and she would laugh or cry without obvious cause; memory and volition were poor. There was an intention tremor of the face and limbs, with loss of muscular power. The deep reflexes were exaggerated; anesthesia with ill-defined outline existed below the elbows and knees. The pupils were dilated, but responsive.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Course of Disease.—She developed a feeble heart, numerous small bedsores, incontinence of urine and feces, and died at the end of four weeks.

Autopsy.—The brain and cord were found congested and edematous, and the pia cloudy. The vascular walls were thickened by infiltration of leucocytes. Scattered through the brain and in the gray matter of the cord were numerous small hemorrhages, and thrombotic areas of degeneration. In certain areas no nerve cells were to be found, and they were replaced by newly-formed neuroglia tissue. The neuroglia cells were swollen, and the lymph spaces choked with cells and granular matter.

CASE 2.—This case, showing the intermediate stages, was that of a man, aged 40, seen in the Kings County Hospital.

History.—He worked as a laborer, and is said to have been in good health until two months before admission, when he fell down a flight of stairs. He was stunned, bruised about the head and body, and rapidly developed a spastic paraplegia.

Examination and Course of Disease.—Examination showed speech to be slow and indistinct. There was rigid muscular atrophy with flexion of the limbs, and an intention tremor of the face, tongue and hands. There was fibrillary twitching in the calves at times. The deep reflexes in the limbs were increased with absence of the plantar reflex. There were ill-defined anesthetic areas below the middle of the forearms and in the legs. There were several small bedsores and retention of urine. Death occurred after five weeks.

Autopsy.—The autopsy findings were similar to those in the first case, but the hemorrhagic areas were in a more advanced state of degeneration, the sclerotic areas were more fully organized, systemic regeneration was present in the cord, and the arterial walls were much thickened.

The three fully developed cases in which an autopsy was obtained presented the following pathologic findings:

The cerebral cortex was flattened and the pia thickened, opaque and infiltrated with serum, leucocytes and granular matter. The veins were dilated and their walls infiltrated with cells. The arterial walls were much thickened. The cortex was thin and pale on section. The cortical nerve cells were much diminished in number, and as a rule degenerated. In variously sized areas no cells were to be found. The neuroglia was much increased and the lymph spaces were dilated and choked, and scattered throughout the brain; in the cords were small areas of sclerotic tissue. Systemic sclerosis was present in both brain and cord.

ETIOLOGY.

This seems to be all the pathologic evidence which we possess to support the theory of an organic basis for this confidence. The evidence furnished the following facts: True cases of this type are not common, for personally, I have been able to find only fifteen in over three thousand cases which have come under my care where some injury to the nervous system existed for which injury was the cause claimed. Nine of these were males and six females. The age at the time of the receipts of the injury varied from 19 to 50. The assigned causes were in three, severe blows on the head, injury to the head and back from falls in three, general contusions from similar falls in two, and five had been thrown about railroad or trolley cars as the result of collisions. In three cases of head injury and in three of general contusion coma was the immediate result, and in the others shock seemed to have been well marked.

As would be expected from the pathologic findings, the development of the symptoms is insidious and the real nature of the condition is only recognizable after a considerable period of time. In my cases this varied between three and twenty-four months, the average being about eight months. During this period thirteen of my cases gave only a history of hysteria or neurasthenia, and of the remaining, one gave the history of an organic paralysis of the arm and the other of an atrophy of the shoulder girdle.

SYMPTOMS.

The symptoms vary both as to number, relative development, and time of appearance. Headache, varying in character and intensity, was present in eleven. Vertigo, either subjective or objective, was also present in eleven. The mental condition showed defective memory and volition, with easily produced laughter or crying in ten. Insomnia was present in ten. The speech was slow, indistinct or syllabic in ten. Nystagmus was present in ten and in three of these associated with strabismus. The pupils were found to be contracted in three, dilated in three, unequal in three, and irresponsive in two. A coarse intention tremor was present in all and rendered the patient's movements trembling, slow and uncertain. This was associated with some loss of muscular strength. Spastic paraplegia was present in eight. The deep reflexes were found to be exaggerated in eight and diminished in six. Areas of partial anesthesia, involving the extremities, never well defined, were present in ten. The visual fields were contracted in eight, and optic atrophy existed in four. Incontinence and retention of urine was present in nine. Besides these symptoms, which are those usually assigned to this condition, thirteen presented also the symptoms ordinarily found in hysteria, one atrophy of the testes, two auditory hallucinations, two epileptic convulsions, one a cerebral hemiplegia, and one a progressive muscular atrophy.

COURSE OF THE DISEASE.

The course of this condition is slow and progressive, with periods of remission. In my three fatal cases, the duration of the disease varied from six to thirty-nine years. Of the other cases, five have progressed, two have developed epilepsy, two have become insane, and of the remaining, their present condition is unknown.

RESUME OF THE LITERATURE.

It will be seen, then, that my cases present the same clinical picture as those described by Dana, Knapp, and Bailey; and form, at least clinically, a distinct group of cases as the result of trauma, but the real nature of these cases, as shown by recent writers on this subject, is still a question open to discussion.

The evidence furnished us by these authorities may be summed up as follows: Bailey, in his work on Accident and Injury, describes them under the title of the "Unclassified Forms," and states that there is no definite knowledge as to their pathology; that he does not claim a common pathology; that some owe their origin to scattered foci of morbid tissue in the brain and possibly the cord, such as occur in the brain in cerebral enteritis, or in the whole cerebrospinal axis in multiple sclerosis; that it is reasonable to suppose that, in these cases, the injury added to the activity of a process already existing rather than caused a sclerosis in previously healthy vessels; that there can be no doubt that minute multiple lesions can occur in the brain and cord from injury giving evidence of commotion, without indicating any particular part injured; that these disseminated areas of hemorrhage best explain the tremor, increased reflexes and psychic inhibition and that in many cases hysterical and organic symptoms co-exist.

Dana[1] states that in some rare cases traumatism may produce multiple minute hemorrhages throughout the nervous centers; that there are usually neurasthenic and hysterical symptoms with those of organic disease; that these cases eventually resemble disseminated sclerosis, and, in Hamilton's System of Legal Medicine, he describes them under the title of the "Grave Neuroses," and further states that, in his opinion, all cases of multiple sclerosis are either traumatic neuroses or the result of acute infectious disease, and that it must be the multiple minute hemorrhages which set up foci of softening, which are followed by the formation of connective tissue nodules.

Oppenheim[2] states that shock may be followed by arterial sclerosis, enteritis, and hyaline degeneration.

Knapp[3] describes this condition under the title of "Traumatic Sclerosis;" states that the evidence that these obscure affections are due to structural lesions is very slight, and that cases of disseminated sclerosis may be caused by injury.

Strümpel[4] states that if a disseminated myelitis should actually follow an acute disease and lead to the formation of multiple sclerotic nodules, this would be an affection similar to multiple sclerosis and yet essentially different.

Starr,[5] in writing on multiple sclerosis, states that the recently reported cases of Gaupp and Blencke are undoubtedly traumatic.

CONCLUSIONS.

This brief résumé, then, presents to us all the real evidence which is furnished by the pathologic findings, clinical observation, and the opinions of recent writers on this subject. It now remains for us to consider the facts in evidence and to apply such rules of exactness as our medical science furnishes in determining the nature of the condition in question. The marked part which neurasthenia and hysteria, as has been said, play in this class of cases, as they do in many other forms of organic nervous disease and especially those cases which follow trauma, has undoubtedly caused some to classify this condition as a type of these neuroses, but when we take into consideration the nature of the real symptoms, such as the syllabic speech, true nystagmus, the pupillary reactions and optic atrophy, the character of the tremor, the character of the reflexes, the true ataxia, the character of the anesthesia, the vesicle paralysis, the bed sores, the fatal course of the disease, and the pathologic findings, it can not be disputed that we are dealing with an organic disease of the nervous system rather than with a neurosis.

The consideration of the nature of this condition has been complicated by the occurrence of a class of cases, first described by Westphal and later by Strümpell, under the name of pseudo-sclerosis. This condition is said to closely resemble multiple sclerosis, to run a long and fatal course, and for which no pathologic basis can be demonstrated. This condition, it is said by Strümpell, can be distinguished from multiple sclerosis by its very marked oscillatory tremor, by the absence of real ataxia, and by its mental condition, in which there are causeless outbursts of wrath and actual maniacal attacks. Personally, I have seen but one such case, but these clinical differences and absence of pathologic findings sharply distinguish it from the condition under consideration. It would appear, then, that beyond a reasonable certainty, this condition in question is one of organic disease of the central nervous system, and that the sole question left at issue is: Is it a form of multiple sclerosis or a distinct pathologic entity?

Taking the pathologic description given by Starr[5] of multiple sclerosis, as a standard, it appears that the condition now under consideration differs from that disease in certain pathologic findings. This writer states that multiple sclerosis is never limited to definite tracts; that it does not lead to secondary degenerations in the various tracts because it spares the axons; that the patches consist of neuroglia fibers and glia cells, and that the essential factor is the production of neuroglia fibers and the disappearance of the myelin sheaths of the nerve fiber. It is in evidence, then, from the facts furnished by the pathologic findings in the class of cases in question, that these cases differ from true multiple sclerosis in the fact that secondary and systematic degenerations do occur; that the axons are destroyed, and that the patches of morbid tissue consist more of fibrous and less of cellular tissue than those found in true multiple sclerosis. This supports the theory of Strümpell, that this condition is similar to and yet essentially different from true multiple sclerosis.

The contention of Bailey and Meyer, that the diseased condition found in the arteries is due to an accidental predisposition and is not one of the essential pathologic processes belonging to the disease, seems to be contradicted by the facts in evidence, for, as it has been shown, this arteriosclerosis is a constant occurrence which is improbable were it only an interposed condition; that vaso-motor paresis with dilatation is one of the natural results of cerebral commotion[6], and that this dilatation may be followed by infiltration and thickening of the vascular walls. It appears, then, from the facts in evidence as furnished by pathologic and clinical observation and from the opinions of recent writers on this subject, that traumatic sclerosis is an organic disease of the cerebrospinal axis; that trauma is a competent producing cause, and that it is not a type of multiple sclerosis but a distinct pathologic entity.

29 South Portland Avenue.

DISCUSSION.

DR. EDWARD B. ANGELL, Rochester, N. Y., said that pathologic conclusions from these cases are unusual because few cases reach autopsy. The period of time during which the degenerative changes occur sometimes lasts so long that the patient passes from under observation. In a certain limited number of cases of trauma there are organic changes in the cerebrospinal axis, but there are a large number in which there are no such changes. Dr. Angell believes that a great deal of confusion has been brought about by trying to establish a new symptom-complex in traumatic diseases of the nervous system. The term "railway spine,". as used by Ericson, expresses injuries of the spine due to trauma and is a very misleading term. Dr. Brush's work will help to clear up a great deal of misunderstanding. A man recently came to Dr. Angell's office who had been injured in a railroad wreck. He was thrown from the train, striking on his back in an adjoining canal, and apparently suffered no injury, being a strong, healthy, robust man. Six months after the accident he noticed a disturbance of the muscular system and at the present time there is a well-developed case of muscular dystocia. In this case the symptoms did not follow the usual course. Undoubtedly, primarily, the organic changes are very minute, but the secondary degenerative changes are sometimes very extensive and not usually accompanied with definite symptoms until some time after the date of the injury. In Dr. Angell's experience in medicolegal matters he has found that many clinicians and neurologists are misled by the appearance of the patient who receives the injury and by the various symptoms of which he complains. The cases should be studied carefully, irrespective of this specific injury, and in this way the truth will be arrived at. In another case, illustrative of the other type, a man received an injury in a railway collision by being thrown down an embankment. There was marked evidence of hysteria and some suggestions of organic trouble. After the settlement of the suit, in which he got about $10,000 or $12,000 in damages, he rapidly recovered. Two years after the trial he was practically a well man and nearly all these pathologic symptoms had disappeared. Dr. Angell believes that the subsequent organic changes depend very largely on the previous health of the neuron receiving the injury. Not all people have a nervous system that is equal in longevity to their arterial system and in minor accidents at times there may be degenerative changes in the nervous system which are not wholly due to the injury.

PREVALENCE AND PROPHYLAXIS OF PNEUMONIA.*

EDWARD F. WELLS, M.D.,

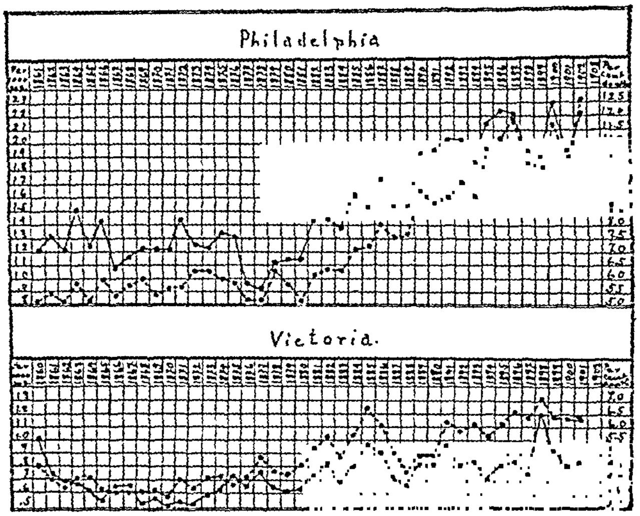
CHICAGO.

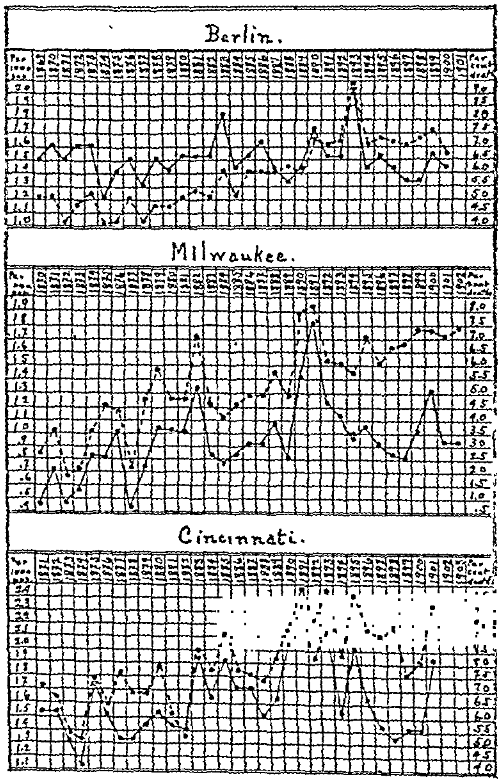
Two years ago I presented to this Section a paper on the fatality and increasing prevalence of pneumonia. with suggestions for individual and communal prophylaxis, and this communication should be considered as being supplemental to that paper.

When we subtract from our mortality bills the deaths caused by infectious diseases, e. g., tuberculosis, malaria, typhoid fever, dysentery, diphtheria, scarlatina, plague, etc., it will be found that comparatively few remain. Such infectious diseases are all essentially preventable, and might well be theoretically wiped off the face of the earth. In the case of some of these this will surely come to pass within a measureable time, but in the case of others this happy period is yet in the indefinitely far-distant future. In the case of some of the great infections. notably tuberculosis, malaria and typhoid fever, the causes, modes of conveyance and methods of prevention are so well known and available that we can contemplate their future with considerable complacency.

Pneumonia is the one great infection in which no systematic and strenuous efforts have, as yet, been made toward prevention. Clearly this has been due to our ignorance of the manner in which the pneumococcus acts as an efficient cause of pneumonia; of avenues of infection and manner of germ diffusion; of efficient and available methods of prevention. The time is now at hand, however, when, with a wider and more exact knowledge of fundamental facts, we are probably in a position to inaugurate a great forward movement in the prophylaxis of pneumonia. In my opinion, we can formulate rules for prevention which will appeal to the reasoning mind of the practitioner of medicine and to the common sense of the layman and which are sufficiently available to meet the exigencies of every-day life. Certainly the conditions are such as to invite a very careful consideration of the subject from every point of view.

Pneumonia is a very prevalent disease and its prevalence is markedly increasing. This increase applies to the deaths per 1,000 of population and to the percentage of total deaths. It probably also applies to the morbidity of the disease, but we lack statistics to positively prove the assertion. The increasing mortality prevalence of pneumonia is graphically shown by the above curves. In these curves the solid line indicates deaths per 1,000 of population. the dotted line per cent. of total deaths.





To what influences may this increased prevalence of pneumonia be attributed? That it is due to any general deterioration of the resisting powers of the populace to morbid infections is disproved by the fact that the average duration of life has been distinctly lengthened during the period of years covered by our inquiry. It is likewise improbable that there has been any general increased vulnerability to this particular bacterial infection. We are, therefore, driven to the conclusion that the pneumococcus has become more prevalent, probably more virulent, or that our opportunities for encountering the germ have been multiplied, or, more likely, that each of these is operative in bringing about the results mentioned. With the pneumococcus as a common parasite in the upper respiratory passages of man, and with pneumococcus-laden secretions from these parts extruded in such manner that they find entrance, as spray or dust, into the respiratory passages of other and unaffected persons, the very general absolute and proportional increase of urban populations and the augmented facilities for travel and the universal tendency for people everywhere to congregate and mingle together, is amply sufficient to account for much, if not the whole, of the increased prevalence of pneumonia.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

During several months I have carefully examined the secretions from the respiratory passages, oftenest from the throat, in 135 persons, and found the pneumococcus present in 61, or 45 per cent. This proportion, it will be noted, is very much greater than that usually found by other observers. In this connection it may be stated that in a considerable number of cases repeated examinations were made, and that in the majority both smears and cultures were examined. The specimens were stained by the Gram method, using a freshly made gentian violet solution and counter staining with pyronin. In the instances in which both smears and cultures were made the pneumococcus was found most readily and oftenest in the smears. The preparations were subjected to careful and prolonged examination, the pneumococcus being the object sought for it was probably found oftener than it would have been were it noted only incidentally. In the majority of the cases the number of pneumococci found were either few or moderate. In some instances the pneumococci were numerous and in a few they were very numerous. In one case, a man who had had pneumonia six years before, and now ill with severe tonsillitis, the germ was present in extraordinary abundance.

At my request Dr. Reynolds, commissioner of health for Chicago, had a special report made on this subject by the director of the municipal laboratory, which is herewith appended:

Chicago, May 26, 1904.

Arthur R. Reynolds, M.D., Commissioner of Health.

Dear Sir:—In reply to your note of yesterday regarding the number of times pneumococci were found in the laboratory specimens, I beg to say that during the month of April ninety-six throat cultures were examined in the laboratory, and pneumococci were found in large numbers in six of these cultures. This would be a little over 6 per cent. I think, however, that if we made a special stain each time we would find a few pneumococci present in a greater percentage of the cases.

I had hoped to make a special stain of each culture in order to give Dr. E. F. Wells, 4744 Woodlawn avenue, a complete report as to the number of times pneumococci are found, whether they be the predominating organism or not. However, the moderating weather that we have had lately has produced a marked decrease in both pneumococci and influenza bacilli, so that 6 per cent of the cultures is about the average for the present.

Very truly yours,

J. F. Biehn, M.D., Director of the Laboratory.

In making these observations there was early noted a peculiar and, I believe, important fact, namely, that in some families every, or nearly every, member had the pneumococcus in the throat, while in some other families no member showed the organism. Comparing these various observations, it was further noted that the majority of the families in which the pneumococcus was peculiarly prevalent had had, more or less recently, one or more cases of pneumonia, while the families in which the germ was not found were, as a rule, without such history. For example:

Case 1.—In 1899 a man, aged 57, had pneumonia. His sputum, examined several times and as recently as last November, always showed pneumococci. He died in December from valvular disease of the heart. On December 10 smears were made from the throat secretions in the case of the widow and also a servant who had been in the family for many years, and in both a few pneumococci were found. They were both suffering from influenza at the time.

Case 2. A man, aged 40, had pneumonia in 1898. In April, 1904, he had a very severe attack of tonsillitis, with the pneumococci as the pathogenic germ present in immense numbers. A few days later smears and cultures were made from the throats of the three other members of the family, and pneumococci were found in each.

Case 3. A man, aged 57, had pneumonia in April, 1904. Of three other members of the family two had pneumococci in their throats. Two other persons who had been in the same house for several weeks did not show the organism.

Case 4. In February, 1904, a man died of pneumonia. A few weeks later examination showed pneumococci in the throats of his widow and a servant who had long been in the house.

Case 5. Two years ago a child had two attacks of pneumonia within a year. The throats of four other members of the family contained pneumococci, while they were absent in the case of the servant who had been long in the house.

Case 6. Four years ago a man, aged 66, had pneumonia. One year ago his wife died with the same disease. Pneumococci are present in the throats of the gentleman and also in another member of the family. Two other persons who have recently become members of the family appear to be free from the organism.

There are exceptions, some of them marked, to the rule:

In one family a boy had pneumonia with middle-ear and mastoid suppuration three years ago. Of the three other members of the family all appear to be free from the pneumococcus. In another family a child had pneumonia three years ago. Of the four other members of the family two have and two have not the germ in their throats. In yet another family the mother has recently had pneumonia, while the pneumococcus has been found in the throat of only one of the other seven members. In yet another family the pneumococcus was found in the throats of each of the four members, although no case of pneumonia has ever occurred in that family.

It would seem that this fact, if confirmed by further observation. offers a plausible explanation for the house epidemics and consecutive family cases which are sometimes encountered.

At the present moment, with an increasing prevalence and case mortality and an unsatisfactory therapeusis, the hope for the immediate future in pneumonia lies in the line of prevention. What can we do to prevent this disease? I answer as follows:

1. For the Individual:—The nasal, pharyngeal and oral cavities should be kept as clean as possible and especially free from accumulations of mucus. When it has been demonstrated that such secretions contain the pneumococcus these efforts should be particularly well directed and maintained. In coughing and sneezing a protective cloth, preferably moistened, should be held

before the mouth and nose. This is especially necessary in the case of pneumonic patients and in those harboring the pneumococcus. The sputum and other secretions of the respiratory tract of such persons should be destroyed before they have become dried. Individuals should, so far as practicable, keep out of range of the extruded pneumococcus-laden secretions of infected persons.

2. For the Public:—The above advice, properly formulated into plainly and succinctly stated rules, should be widely and persistently circulated by the communal health authorities among the laity, and practicing physicians should be furnished a supply of these rules, neatly printed and without imprint, with the request that they give it as their instructions to their patients and clientele. And further, by every means, the interest of physicians and humanitarians in this subject should be aroused and fostered. For this purpose special societies and committees might be formed for the purpose of studying the problem and furthering the efforts of the various health bodies, as has so successfully been done in the case of tuberculosis.

DISCUSSION.

Surgeon-General Sternberg, Washington, D. C., stated that he made a good many experiments as long ago as the winter of 1880, when he first discovered this micrococcus of pneumonia, and he found that it was very pathogenic for rabbits. He went to Philadelphia during that winter for the special purpose of finding out whether this micro-organism was to be found in the mouths of other healthy individuals or whether it was peculiar to himself. He made numerous experiments with the saliva of students in Philadelphia and in Baltimore. The organism was found in a considerable proportion of the cases examined, and there seemed to be quite a difference regarding its virulence as obtained from different individuals. Subsequent observations made in Germany and in this country have shown that it is a widely distributed organism quite as common as the streptococcus pyogenes and other pyogenic micrococci. All these pathogenic bacteria lose their virulence when they lead a saprophytic life for some time. As the pneumococcus is found in the mouths of healthy individuals it must be considered a saprophyte. The pneumococcus found in the sputum of pneumonia patients, as a rule, is more virulent than when found in the mouths of persons who have not suffered from pneumonia. Dr. Sternberg is a little in doubt as to the ability of bacteriologists to say positively that they find the micrococcus of pneumonia in smear preparations. There are other organisms which resemble it so closely morphologically that he could hardly say that he had it unless he had found it in cultures or had obtained it from inoculations of susceptible animals. Referring to the danger of persons carrying this micrococcus in the salivary secretions, Dr. Sternberg stated that he had made frequent inoculations in rabbits with fatal results, showing that he carried this micro-organism in a virulent form in his salivary secretions. It is evident that something more than the micrococcus is necessary in order to induce the disease—a lowered vitality from insufficient nutrition, loss of blood, overwork, alcoholism, insanitary surroundings, etc. Dr. Sternberg considers that the prevention of pneumonia by disinfection is a difficult thing to carry out on a large scale when it is considered how widely the pneumococcus is distributed. Prophylaxis must depend largely on combating those causes which make the individual susceptible and Dr. Sternberg considered that the micrococci in the sputum of pneumonia patients should always be destroyed, but he doubts whether it is practical to destroy the micrococcus in the mouths of healthy individuals, or of those convalescent from pneumonia as a general measure of prophylaxis.

Dr. George M. Kober, Washington, D. C., said that he thinks that sufficient importance has not been given to the predisposing causes of pneumonia. The exciting causes have been pointed out by the preceding speakers. The increased consumption of alcohol in the United States is one of the most important predisposing factors. Students of the United States census statistics will observe that while the general death rate has decreased there has been a positive increase in all diseases that are believed to be caused, or at least influenced, by the habitual and undue consumption of alcohol. It is also a fact that the national drink bill has increased from year to year, and that the amount of liquor consumed per capita is simply enormous. Dr. Kober thinks that there are statistics indicating that the consumption has increased, so that the amount now consumed is about eighteen gallons per year per capita in the United States. At all events the general statistics clearly point to an increased consumption of alcohol, and he believes that it is not only a question of alcohol, but a question of the purity of the alcohol. The heavier alcohols are toxic and affect the tissues of the body, lowering the vitality to a great extent, first destroying the moral, intellectual and physical sensibilities. One of the most common effects is, perhaps, an impure blood supply and degenerative changes, because alcohol, apart from increasing connective tissue, favors the conversion of albuminoid tissues into fats, and, therefore, there is an increase of chronic affections of the kidneys, cirrhosis, hepatic diseases, heart disease and all other diseases caused by alcoholism. The vital statistics of 1900 give an increased death rate from these diseases, and Dr. Kober believes that the secret, after all, lies in the increased consumption of alcohol in the United States, and possibly in a general tendency to adulteration of liquors. While Washington is exempt from an increase of pneumonia, it is, perhaps, due to the fact that it has a large negro population, and there seems to be among them a racial distaste for alcoholic liquors; at all events, the negro is not a drunkard. The ratio of diseases believed to be caused by alcohol among the negro in Washington is infinitely less than among the whites, and yet in all other diseases the death rate among the negroes is very much higher than among the whites. They seldom have a death from cirrhosis or from arteriosclerosis. Indeed, all of those diseases that are influenced by alcohol are scarce among the negroes, and yet their general death rate is far in excess in all other diseases.

Dr. John S. Fulton, Baltimore, said that if it is true that pneumonia has increased, which he is inclined to doubt, it would be very interesting to discover the cause, and it is necessary to learn first what parts of the population have suffered the increased mortality; for the mortality has not been equally distributed either according to age or locality. The particular point of interest to him at the present time concerns the exceptions, and especially the one to which Dr. Kober has alluded, the District of Columbia. Dr. Fulton believes that the residents of the District of Columbia have overlooked one fact which may explain their exemption from an apparent rise of pneumonia rather better than to attribute it to the non-use of alcohol by the negroes. Very likely the increasing use of alcohol is in part responsible for the fact that pneumonia is not diminishing as rapidly as it should at some periods of life, if it be true that the per capita consumption of alcoholic beverages is increasing. He has no doubt that between the ages of 15 and 60 the mortality in pneumonia has been decreasing, and here, if anywhere, the influence of alcohol should appear. The age distribution in the District of Columbia, to his mind, explains the apparent exemption of the district from the increased death rate of pneumonia. He is not sure that there has not been a rise in the District of Columbia in the mortality from pneumonia at certain periods of life. The population in the district lacks those elements of population which contribute to the increase of pneumonia. There are fewer people in Washington under the age of 15 years than in any other part of the United States save only the very newest settlements. Above the age of 60, also, Washington has a relatively small population, while between the ages of 15 and 60 the population is proportionately large. Political conditions dominate the age distribution of the population of the District. It has not and never will have an age distribution comparable with any other urban population. Washington will always have a relatively excessive population in the active period of life. It has also a very considerable excess of females between 20 and 40. Pneumonia at the most important period of life appears to be diminishing, and Washington has precisely the elements of population which enable her to profit by this decline. If the mortality of the District could be equated so as to be comparable with that of such cities as New York, Chicago, Richmond and Baltimore, the true state of affairs would not be found just such as the raw figures indicate. It might appear that Washington has had an increased mortality from pneumonia at a certain period of life, namely, below the age of 5. If pneumonia has really increased, Dr. Fulton's opinion is that the increase has fallen on very early life.

Dr. E. F. Wells said that in presenting this paper he intentionally allowed every mooted question, as he thought, to remain out of the paper. The basis of the belief, for example, that the pneumococcus is the cause of pneumonia, the bearing which different strains of pneumonia have on the characteristics of the disease, the possibility of infinitely increasing or decreasing the virulency of each of these individual strains, the connection between the organism which Surgeon-General Sternberg found in his own mouth, and in the mouths of others, and that of the organism found in pneumonia, and the evidence on which we believe one to be the same as the other, he entirely omitted, and intentionally, because he did not wish to take up time. He desired to present as clearly as possible certain facts which he believes have a bearing on the propagation and increasing prevalence of pneumonia, and to offer some suggestions by which it might probably be diminished. In another section he presented some facts along these lines, which, however, are well known, that not only are the pneumococcus and other pathogenic organisms distributed by means of the sputum from the throat and nose of men and women, but in a more insidious manner, by coughing and sneezing, and throwing a minute number of particles into the air, with a possible and probable bearing on the dissemination of this organism and the increasing prevalence of pneumonia. Dr. Wells said that he feels fairly sure of the ground on which he stands, and will continue his efforts to find a public ready for reasonable and available methods for the prophylaxis of pneumonia.

THE RELATION OF THE INTERNAL SECRETIONS TO EPILEPSY, PUERPERAL ECLAMPSIA AND KINDRED DISORDERS.*

CHARLES E. DE M. SAJOUS, M.D.
PHILADELPHIA.

A suggestive coincidence bearing directly on the disorders referred to in this paper, epilepsy, puerperal septicemia, tetanus and hydrophobia, is that several investigators have been led to conclude by experiments, in which each organ was studied individually, that the adrenals, the pituitary body and thyroid not only influence metabolism, but that they are also concerned with the destruction of toxic waste-products. Thus, in 1891, Abelous and Langlois[1] advanced the view that the function of the adrenals was to "neutralize or destroy toxic substances produced or elaborated during chemical interchanges, and particularly those resulting from muscular work." In 1894 Lloyd Andriezen[2] concluded that "the pituitary gland exercises a trophic action on the nerve tissues, which, in more definite terms, means enabling them, *a*, to take up and assimilate oxygen from the blood stream, and, *b*, to destroy and render innocuous the waste-products of metabolism." As to the thyroid, it may be said to have been connected with both these processes almost since any function was ascribed to this gland. "According to one hypothesis," says Howell,[3] "the function of the secretion is antitoxic. In some way it antagonizes toxic substances supposed to be formed in the body in the course of normal metabolism."

The interpretation of the functions of these three organs which I submitted last year,[4] merges all these hypotheses into a coherent whole; it explains, also, the manner in which metabolism is sustained by all three organs simultaneously, and how the toxic waste products are destroyed. When we consider the vast array of facts on record attesting to a close relationship between these toxic wastes and the diseases in question, it can not but appear that the interpretation referred to may serve to throw some light on the pathogenesis of these diseases, and, perhaps, open new lines of thought in the direction of their treatment.

Since my views were published considerable personal work and new facts contributed by experimenters have only served to strengthen the position then taken as to the functional relationship between the adrenals, the pituitary body and the thyroid. To illustrate the connection between the interial secretions and the diseases mentioned, it is necessary to briefly review the evidence attesting the existence of what I have termed the "adrenal system" as it appears enriched by these new facts.

The marked blood pressure raising power of adrenal extractives and their action on the heart are well known. That the secretion of the adrenals produces identical effects has been established experimentally.

Gottschau,[5] Stilling,[6] Manasse[7] and Auld[8] observed that hyaline masses were secreted by rows of cells in the medullary canal of the organ, and that pressure on the latter caused these masses to pass into the blood vessels. Pfaundler[9] discovered similar masses in the latter and in the suprarenal vein where it opens into the vena cava. Cybulski, Szymonowicz[10] and Langlois[11] then ascertained that blood drawn from the suprarenal veins produced effects similar to those that follow injections of adrenal extracts, and Biedl[12] found that, while blood taken from other veins produced no effect when injected intravenously, blood taken from the adrenal veins used in the same way produced the characteristic effects of adrenal extracts, i. e., slowing of the pulse followed by a rise of blood pressure.

How is the functional activity of the adrenals increased? To ascertain the identity of their secretory nerves, Biedl tied the vena cava below the adrenal veins, inserted a small canula above the latter, and registered the number of drops of blood that escaped from it. On dividing the splanchnic and stimulating its peripheral end, the number of drops increased, but only after from seven to ten seconds, then gradually to from three to five times the normal number. The increased flow continued from ten to twenty seconds after stimulation had ceased. Stimulation produced no effect when the suprarenal nerves were cut. This showed that the splanchnic contained nerves which increased the blood flow through the adrenals—as does the chorda tympani in the submaxillary gland—but did not disclose the identity of the secretory nerves. This was accomplished by Dreyer[13] of Johns Hopkins. He ligated the adrenal vein so as to secure, through a canula, only blood derived from the gland. In eight experiments a given bulk of adrenal blood taken during stimulation of the splanchnic produced decidedly greater effect than the same blood before stimulation. The greater splanchnic was thus shown to contain fibers which, on excitation, increase the functional activity of the adrenals.

Biedl also tried to prove experimentally the presence of vasoconstrictor nerves in the adrenals. Stimulation of the (cut) splanchnic, vagus and of the suprarenal nerves failed to show the least constriction; asphyxia, which causes marked vasoconstriction in the intestines, also failed to cause it in the adrenals. He then exposed and divided all the spinal roots from the third thoracic to the third lumbar, and stimulated both their anterior and posterior segments "with a strong induction current." No vasoconstriction occurred in the adrenals, though the usual effects were noted elsewhere, and the rapidity of the blood flow from the adrenal veins was never increased.

This experiment was repeated three times, and always gave similar results. It shows not only that the adrenals are not supplied with vasomotor nerves, but also that the secretory nerves to the adrenals do not originate in the spinal cord up to the third thoracic.

Again, if the adrenals' secretory fibers are present in the greater splanchnic, which arises from the sixth ganglion of the sympathetic cord, some splanchnic fibers —those to the adrenals—must ascend in the sympathetic cord at least to the level of the second thoracic. Quain[14] states that some fibers of the splanchnic's higher roots "may be traced upward in the sympathetic cord as far as the first or second thoracic ganglia." Gray[15] gives the same limits; Curveilhier[16] says that these upper filaments "are merely in contact with the sympathetic," a statement which obviously suggests that they constitute an autonomous path.

Stimulation of the sympathetic cord alone above the origin of the splanchnic nerve, i. e., up to the first thoracic ganglion, increases the functional activity of the adrenals.

We have seen that when Biedl stimulated the splanchnic the functional activity of the adrenals increased only after from seven to ten seconds had elapsed, and that it continued from ten to twenty seconds after the excitation ceased. The intestines react in a similar way. If "a galvanic current be passed through the splanchnic nerve," says Brubaker,[17] "no instantaneous effect is noticed, as in the case of the cerebrospinal nerves, but in the course of a few seconds a slow, progressive contraction of the muscular coat of the intestine is established, which continues some time after the irritation is removed." If this is due to hypersecretion of the adrenals, the intestines are thus subjected to two experimental vasoconstricting influences: the adrenal secretion and their own vasoconstrictor nerves. Intestinal "inhibition" affords evidence of this dual action. Schiff, Ludwig and Kupffner, Bechterew and Mislawsky[18] have observed both a motor effect, i. e., increased peristalsis sometimes, and inhibition at others. Bunch[19] has given graphic records of intestinal movements in which stimulation of the splanchnics caused in some animals augmentation, in others inhibition of the intestinal tone." Starling[20] says in this connection that Jacobi[21] found that "section of the nerves running from the suprarenals to the solar plexus annuls the inhibitory action of the splanchnics (on the intestines) without affecting their vasoconstrictor effects." This plainly shows that when the adrenals are no longer stimulated through section of their secretory nerves the constrictor (experimental) effects caused by the vasomotor nerves continue alone.

The same dual action occurs in all other organs supplied with vasomotor nerves. In the liver, for instance, two forms of experimental vasoconstriction are discernible; one due to the true vasoconstrictors, which nerves, as shown by François-Franck and Hallion[22] and confirmed by others, leave the spinal cord from the sixth thoracic to the second lumbar, inclusive; the other due to stimulation of the sympathetic cord above the sixth thoracic. The above-named physiologists found that stimulation of the sympathetic chain where, they state, "it has not as yet received from the spinal cord the first hepatic vasoconstrictor rami," caused "a marked rise of aortic pressure." They then divided the rami containing all the hepatic vasomotor nerves, thus isolating the sympathetic chain, and stimulated the latter above the origin of the upper root of the splanchnic. This provoked, as stated by them, and as shown by their tracings, "the maximum vasomotor effect," while division of their upper root was followed by "marked reduction of the vasoconstrictor effect." The upper root referred to, however, being the identical one which, we have seen, anatomists trace up to the first thoracic ganglion, similar effects should be obtained higher up in the sympathetic chain.

Referring to experiments recorded by Pavy, Cyon and Aladoff, and François-Franck, some twenty years before. François-Franck and Hallion remark that they had "led to the supposition that the hepatic vasomotor nerves passed down to the loop of Vieussens by the cervical sympathetic cord, and thence to the thoracic chain through the stellate inferior cervical ganglion." Unable, of course, to account for their results, they ascribed them to "reflex action" or to some unexplained "indirect influence."

Still, the loop of Vieussens, to which these physiologists refer, forms part of the cervical sympathetic, and lies above, therefore, the upper limit of the splanchnic fibers, the first thoracic. How account for the effects noted?

In 1859 Pavy[23] found that "division, on both sides of the neck, of the ascending branches of the superior thoracic ganglion" in the vertebral canal caused "an intensely marked diabetes." Francois-Franck and Hallion refer to these branches collectively as the vertebral nerve, composed of the rami of the sixth, seventh and eighth spinal nerves, and the one which on stimulation caused hepatic vasoconstriction. Glycosuria is now generally attributed to a too rapid conversion of the liver glycogen into sugar, i. e., to excessive functional activity. Even Bernard's puncture is ascribed to localized irritation.

This interpretation is sustained by the fact that adrenal extract, as shown by Blum,[24] Croftan[25] and others, cause glycosuria. Herter,[26] for example, found that intravenous injections of adrenalin were followed by a large excretion of sugar, and states in this connection that "a rise of blood pressure is an accompaniment of glycosuria." Stimulation of the adrenals can alone, therefore, bring about glycosuria and its corollary a rise of blood pressure. Moreover, Claude Bernard found that experimental diabetes was prevented by division of the splanchnic. It follows, therefore, that division of the vertebral nerve should prevent diabetes if it were the secretory nerve of the adrenals. Indeed, the vertebral nerve is what Pavy termed it from the start, namely, a sympathetic nerve—an important one, as we will see, since it terminates in the organ from which the nerve to the adrenals originates.

Cyon and Aladoff[27] found that lesions or removal of the upper thoracic or inferior cervical ganglia, or division of the loop of Vieussens, also caused diabetes. All these contain, as is well known, sympathetic fibers which ascend to the superior cervical ganglion. Again, Pavy states that "of all the operations on the sympathetic of the dog that have as yet been performed, removal of the superior cervical ganglion the most rapidly and strongly produces diabetes." Hence, some of the ascending fibers referred to must transmit their vasomotor impulses to some cranial organ which, when passively congested and overactive through section of these fibers, can in turn stimulate the bulbar centers and produce glycosuria. That we are dealing with a vasomotor path is further emphasized by the "temporary nature" of the diabetes witnessed by Pavy.

Which is the cerebral organ thus influenced? Langley[28] refers to three bundles of fibers given off by the superior cervical ganglion, the distribution of which is uncertain. Two of these pass toward the eye muscles; of the third he says: "there is that which accompanies the internal carotid; it would naturally be supposed to convey vasomotor fibers to the vessels of the brain, but this view, as we have said, is contested." The carotid plexus is connected with the pituitary body. So distinct is this connection, and so direct is the anatomic relationship between this organ and the sympathetic chain, that Bourquery, a French anatomist, looked on it some forty years ago as the general center of the sympathetic system. Hirschfeld[29] says in this connection: "I am all the more inclined to adopt this view, since I have always seen in my dissections a great number of nerve fibers extend from the superior cervical ganglia to this organ." Among the anatomists who have also found these fibers are Pourfour du Petit, Fontana, Bok, Sappey, Hirzel, Warrentropp and Bazin, and among the more modern works which refer to them are those of Testut,[30] Morris[31] and Gerrish.[32] On the other hand, Berkley,[33] after an exhaustive histologic study of the nervous supply of the pituitary body, says, referring to its anterior lobe: "All nerves belonging to it appear to be derived from branches of the carotid sympathetic plexus."

To control this evidence, it should be possible to show that overactivity of the pituitary body, hyperemia of the bulbar center caused by Bernard's puncture and injections of adrenal extractives can cause diabetes. We have seen that Bernard prevented experimental glycosuria by dividing the splanchnics; Loeb[34] states that glycosuria does not occur during the post-operative life of animals deprived of the pituitary, and that it is a frequent symptom of pituitary growths. Again, Berkley, as stated, traced the fibers of the carotid plexus to the anterior lobe. Sternberg[35] found that this lobe was chiefly involved in acromegaly. Tamburini,[36] in a study of acromegaly which included twenty-four autopsies, lays stress on the fact that exaggeration of the functions of the pituitary attends the first stage. The excessive and often ravenous appetite, the thirst, polyuria, the full and hard pulse, cutaneous hyperesthesia, abnormal superficial heat, etc., and the typical muscular and osseous hypernutrition, all indicate excessive functional activity—the underlying factor, we have seen, of glycosuria. Hinsdale[37] mentions fourteen clinicians who have observed glycosuria in this disease.

Again, if overactivity of the pituitary body provokes glycosuria by stimulating the adrenals, we should obtain, on stimulating the pituitary, the characteristic symptoms of overactivity of the adrenals. De Cyon[38] observed, in the course of experiments in a large number of animals (in support of his theory that the pituitary body serves through the thyroid gland to regulate the cerebral blood pressure) that "any, even slight pressure on the pituitary body immediately gives rise to a sudden variation of the blood pressure, and to a marked reduction of the beats of the heart, the strength of which is at the same time considerably increased." He also found that "electrical stimulation of the pituitary body, even with extremely weak currents, produces exactly the same phenomena as mechanical pressure, but in a much more intense manner."

These experiments have been repeated recently by F. Masay and amplified in such a manner as to distinctly locate in the pituitary the origin of the phenomena witnessed. His investigations showed that mechanical and electrical excitation of the pituitary body caused a marked rise of blood pressure—from 81 mm. Hg to 200.

in one instance—and that this effect was not prevented by section of both vagi. He also found that very soon after excitation the power of the heart became "greater than normal." We thus have a marked rise of blood pressure followed by an increase of cardiac power—precisely the physiologic characteristics not only of adrenal extractives, but also of blood taken from the suprarenal veins.

How does the pituitary body transmit its impulses to the adrenals?

Last year[4] I advanced the view that the anterior pituitary body was a sensory organ. This has been fully sustained by recent researches. Paremeschko[39] described a transverse slit or cavity between the glandular elements and the partition, which cavity communicated with the infundibulum, and was lined throughout with ciliated epithelium. Cadiat[40] observed a similar cavity communicating above with the tuber cinereum and lined with pavement epithelium. Müller[41] states that the internal wall of this slit, which forms part of the partition, is composed of a network of lymphatics lined with ciliated epithelium. Recently this region of the anterior lobe has been studied by the Golgi method by Gentès,[42] who found that this lobe was in reality composed of two parts, the glandular and the neural, the latter forming the inner wall of the cavity described by Paremeschko, Cadiat and Müller, which cavity he found to exist in the animals used, i. e., the cat and dog. Ordinary methods of staining suggested that this structure was composed of several layers of cylindrical stratified epithelium, but the Golgi method showed in addition that the interstices between these elements were penetrated throughout by sensory cells, each cell sending broad processes to the free surface and into the depths of the epithelial layer. The latter recalled "precisely that of the olfactory area of the nasal membrane."

Lloyd Andriezen,[2] after tracing the phylogenetic history of the pituitary body in all vertebrates, concluded that "the posterior lobe represents little beyond a neuroglia remnant of what was once a functional portion of the nerve tissue in ancestral vertebrata." My own researches having suggested that neuroglia fibers were not insignificant functionally as now believed, and that they were neural capillaries containing blood-plasma, under the dependence of neuroglia "cells," the posterior pituitary no longer appeared to me as a vestigial organ.

Berkley,[33] after examining about 2,500 slides of this organ, found different types of cells, and expressed surprise to find therein "beautiful specimens of several types of ependymal neuroglia cells extending from all portions of the middle and inferior regions of the cavity of the third ventricle." Kölliker[43] also observed such elements in human pituitaries. Even its outer layer was found by Luschka[44] and Müller,[45] who studied the pituitary body from myxine to man, and others, to be composed of gray substance recalling that of the cortex cerebri and similar to that found in the infundibulum.

As to the relations of the pituitary body with the base of the brain, i. e., the third ventricle, Ramon y Cajal[46] found that the posterior lobe was filled with a close and thick plexus of fine varicose fibers which ramify among the nerve cells. Longitudinal sections showed that these fibers were "terminal arborizations of a bundle which passes downward in the infundibulum." Some fibers were also observed to pass upward from the organ by way of its epithelial walls and to terminate in a mass of gray matter located behind the optic chiasm. Cajal also found that this group of cells (the giant-celled supra-infundibular nucleus) also sent some of their axons into the anterior lobe, terminals of which penetrated between the epithelial cells. This agrees with the description of older anatomists and histologists (Sappey, Luschka, Müller, etc.). Both the anterior and posterior lobes thus communicate through the infundibulum with the central gray substance, a region which Foster terms "a bed for the development of the nuclei of the cranial nerves and a continuation of the spinal gray matter."

The great nucleus above the optic chiasm and the infundibular structures is not only connected with the pituitary body, but also with: 1, the structures anterior to it; 2, the gray walls of the third ventricle on each side of it; and 3, the tuber cinereum or floor of this ventricle (of which the infundibulum forms part), which extends up to the mammillary bodies, two small organs immediately behind the pituitary body. Van Gehuchten,[47] for instance, recently found, in teleosts, that cells in the anterior lobe, which is composed mainly of the olfactory and visual organs, sent some of their "neuraxons" by way of the anterior basal bundle to the anterior portion of the infundibulum where they terminated, while neurons whose cell-bodies were in the infundibular structures sent theirs to the anterior lobe. He characterizes these nerves, respectively, as "motor" and "sensory." This coincides with results obtained in the monkeys by W. Spencer.[48] He slowed and arrested respiration by stimulating an area adjoining the olfactory tract in the orbital surface of the frontal area. The fibers traced by him seem to form part, he thought, of the olfactory tract bundle which passes over the optic chiasm around the infundibulum. Munk[49] has observed a close connection between the frontal respiratory area and the olfactory paths, and on exciting it, could arrest respiration, deepen the thoracic inspiration, and even cause diaphragmatic tetanus. Cyon also caused tetanic spasm by stimulating the pituitary body.

Important in this connection is the fact that anterior connections with the central gray matter exist which are independent of the hemispheres, including the striated bodies and optic thalami. Edinger[50] emphasizes the fact that the prominent olfactory tract runs backward to the level of the mamillary bodies, and "must pass through the most ventral regions of the corpus striatum; but it receives no fibers from this, as has been supposed." In fact, he states that in Goltz's dog—which lived eighteen months after removal of both hemispheres and in which the optic thalami were partially destroyed—"the great tract of fibers from the olfactory field could be traced backward very clearly and distinctly to the corpus mamillare." So are all the structures of the central gray matter independent of the hemispheres. Von Monakow found that removal of the cortex did not cause primary degeneration of the tuber cinereum which contains the infundibulum, or even of the gray substance overlying the optic thalami.

[50] Edinger: Anatomy of the Central Nervous System in Man and in Vertebrates in General, Transl. by W. S. Hall, Philadelphia, 1899.

This entails the need of cellular connections in the various regions of the third ventricle, including its walls, to receive impulses from various directions, irrespective of the hemispheres. Edinger found that in reptiles, amphibians and birds, the nucleus of the infundibulum extends around the walls of the ventricle, and he considers it as the probable source of the "supra-infundibular decussation formed of large fibers, which," he says, "descend to it from the gray matter of the ventricular walls." Again, Van Gehuchten found that while the bipolar cells (which, as is well known, are also present under the rods and cones of the retina, the olfactory membrane and other sensory organs) in the infundibular tissues, sent a tuft of dendrites to the surface of the latter, another tuft of "short irregular extensions terminate on the free surface of the ventricular cavity."

The central gray substance is thus supplied with direct paths from sensory organs and nervous extensions capable of forming links or synapses with others, all so arranged as to concentrate their impulses in the infundibular walls, and thence, judging from the cellular connections, into the pituitary body.

The spinal cord sensory impulses are no exception in this connection. A pigeon deprived of its hemispheres feels a fly that happens to alight on its head, and shakes it off; Goltz's dog, in which, beside the hemispheres, the optic thalami were functionally destroyed, refused food made bitter with quinin; Vulpian has shown that when the hemispheres, optic thalami, striated bodies, the corpora quadrigemina and the cerebellum were removed, animals still cry out when a foot or an exposed nerve is strongly pinched. The central gray axis alone remained here to receive impulses through at least a portion of the fillet, which, according to Foster,[51] is "a probable path of sensations of one kind or another from the body at large."

Two divisions of the fillet are so disposed anatomically as to reach the central gray substance, the fillet layer and the mesial fillet.

Edinger[50] states that the greater part of the former can be traced up from the nuclei of the sensory nerves and the posterior columns. "Meynert," adds this anatomist, "first demonstrated that in it we have a segment of the sensory tract. Embryology and comparative anatomy equally substantiate this position." This layer, also termed the "deep gray-white layer," after decussating in the medulla, passes upward in the gray substance of the aqueduct of Sylvius to the threshhold of the third ventricle. The other or mesial fillet also reaches up to this region; while some of its fibers go to the optic thalami, others terminate in the subthalmic region, i. e., beneath the walls of the third ventricle, which, we have seen, contain dendritic tufts of infundibular nerves. Now the fillet, from which both these tracts originate, not only contains, as emphasized by Edinger, fibers from all the sensory bulbar nuclei, but degeneration experiments have shown, he says, that "it may be separated into its various bundles for the different nerves, trigeminus, acusticus," etc. Stewart[52] refers to the mesial fillet as being enlarged in the medulla "by the accession of fibers from the sensory nuclei of the cranial nerves." In other words, this division of the fillet contains fibers of all sensory nerves, the vagus, glossopharyngeus, trigeminus, etc., and transmits them to the base of the brain.

The central gray substance *per se* can thus receive sensory impulses from all parts of the organism. It can likewise transmit motor impulses to all organs.

Van Gehuchten traced motor fibers to the anterior organs of the head. The motor paths to the spinal cord are clearly defined through the posterior longitudinal bundle, which passes down to the anterior columns of the cord. It is only traced usually to the motor oculi nucleus. Edinger says in this connection: "The posterior longitudinal fascicle sends its most anterior fibers much farther forward than to the nucleus of the oculomotorius. In the central gray matter, just anterior to the beginning of the aqueduct, is a collection of large ganglion cells, from which a number of such fibers (referring to the fibers destined for other cranial nerves) arise—the nucleus fasciculi longitudinalis posterioris.[53] This nucleus is demonstrable in all vertebrates. In mammals it lies in those places which ventrally intersect the posterior part of the corpus mamillare." Moreover, he found that in the human fetus, as well as in the lower vertebrates, it received fibers "from all motor nuclei throughout its long course." Finally, the vast functional importance of this motor path is emphasized by the words: "Inasmuch as it is found in all vertebrates, and always from the interbrain to the region of the anterior columns of the spinal cord, it must be recognized as one of the fundamental features of the brain."

While the central gray substance is evidently endowed with an autonomous mechanism through which it can receive all impressions from the periphery and transmit motor stimuli in every direction, what is the influence of the pituitary body in this connection? We know that it was by passing a current from the nasal cavities to the bulb that brothers Weber[54] arrested the heart. Cyon,[55] while studying experimentally the influence of a supposed secretion of the pituitary body in the cerebral blood pressure, found that inhibitory slowing of the heart could no longer be obtained after extirpation of the pituitary body. Even the reflex phenomena, sneezing, coughing, lachrymation, etc., provoked by irritation of the nasal mucous membrane, could no longer be obtained, irritants of the most active kind, ammonia, for instance, having lost all influence. "All the nerves connected with the nasal mucous membrane capable of causing reflex phenomena," says this physiologist, "that is to say, the end-organs of the trigeminus, olfactory, optic, auditory and glosso-pharyngeus, had lost their influence after the pituitary body had been removed."

When we realize how many different sensory and motor paths are involved in the production of the reflex phenomena referred to, and also that a high mammal deprived of its hemispheres will live months, whereas removal of the pituitary body in an adult animal inevitably causes death, the commanding importance of this organ can not but assert itself. Indeed, I have advanced the view that we have in this organ the governing center of the nervous system, meaning thereby the co-ordination center of the vasomotor and cranial nerves. It is when we observe the perfection with which all purely physical functions are performed in the absence of the hemispheres that the need of such an organ asserts itself, and that the identity of the pituitary body as such becomes apparent.

All this has also served to indicate the path of the secretory nerves to the adrenals.

The vertebral nerve being purely a vasomotor path, it need no longer be considered as a possible secretory nerve to the adrenals. Indeed, François-Franck and Hallion found that section of the five upper thoracic rami communicantes arrested the hepatic vasoconstrictor effects. They justly contend that if the impulses from the upper spinal cord actually passed to the sympathetic chain by way of the vertebral nerve, the vasoconstrictor effects should have persisted notwithstanding division of the thoracic rami.

There is a feature of their experimental result which these physiologists overlooked, however, namely, that if division of these rami, all of which are above the origin of what they rightly consider as the uppermost path (the sixth thoracic) for the true hepatic vasoconstrictors, arrested their constrictor effects, the five severed rami must have controlled these effects. In other words, the functional activity of these vasomotor nerves must have depended on the functional integrity of some organ dominated by the five upper rami. The solution of this problem is easily found, in view of the fact that the portion of the sympathetic chain to which these five rami run is the only portion of this chain in which the nerves traced upward from the adrenals occur alone. It is plain, therefore, that it is by way of these five rami that the impulses, which produced the typical effects of adrenal extractions when the pituitary body was stimulated by Cyon and Masay, were transmitted to the adrenals by way of the sympathetic chain.

What is the nature of the process through which the pituitary body controls the functional activity of the adrenals? I can only recall that I have adduced evidence to show that the secretion of the adrenals, owing to its marked affinity for oxygen, took up this gas from the pulmonary air and became transformed into a compound I termed "adrenoxin." This was found to correspond with the substance which Salkowski[56] Schmiedeberg,[57] and subsequently Jaquet[58] and Abelous and Biarnès,[59] found in the blood, and which they specifically characterized an "oxidizing ferment." It is a constituent of blood serum and of the red corpuscles, and it yields its oxygen to sufficiently potent reducing agents. Its hold on the oxygen is sufficient to present its dispersion and not too great to resist the normal affinity of the tissue with which it comes into contact. The blood plasma laden with adrenoxin can thus circulate in microscopic capillaries, where corpuscles can not reach and sustain metabolism. Methylene-blue stain which, according to Ehrlich, requires oxygen saturation and alkalinity, indicate its presence in all nervous elements, including the nerve cell.

The manner in which the adrenals sustain the functional activity of the vasomotor nerves now suggests itself. The adrenoxin-laden blood plasma sustains the vital process of the vasomotor center, as well as that of the other organs. We have seen that when Cyon and Masay stimulated the pituitary body, the characteristic effects of adrenal secretion or extracts were produced. The blood's adrenoxin acts on it in a similar way, and the effects witnessed are in reality those of overstimulation of the same organ, and the effects evoked point to it as the chief vasomotor center.

Under these conditions the effects of adrenal extracts should coincide with those of the overactive vasomotor nerves. Langley,[60] after an exhaustive experimental study of the physiologic action of adrenal extract, remarks that it "runs parallel with the action of the sympathetic nerves on the blood vessels." He also deems it "noteworthy that the effects produced by suprarenal extract are almost all such as are produced by stimulation of some one or other sympathetic nerve. In many cases," he adds, "the effects produced by the extract and by electrical stimulation of the sympathtic nerve correspond exactly."

Important in this connection also is the fact that it is through some of these rami that the heart is supposed to receive its augmentor nerves, i. e., the three uppermost thoracic. Brown-Séquard,[61] in 1853, emphasized the predominating influence of the venous blood in cardiac dyamism. Oliver and Schäfer[62] and others have demonstrated that intravenous injections of adrenal extract had a powerful physiologic action on all muscles, but particularly on the heart muscle. In my work on the "Internal Secretions," I lay stress on the fact that the heart's contractile power depends to a great extent on the adrenal secretion which enters it by way of the inferior or vena cava, and that the secretion penetrates into the myocardium by way of its Thebesian foramina. This accounts: 1, for the augmentor effects; 2, for a part, at least of the rise of blood pressure which occurs, as is well known, when all the nerves to the heart are cut, and shows that the secretory nerve to the adrenals is a bundle formed of the three upper thoracic spinal nerves, which reach the splanchnic through the upper portion of the sympathetic chain in the thorax.

Biedl, we have seen, only stimulated the spinal nerves up to and including the third thoracic, but as he was trying to ascertain the presence of vasomotor nerves, he doubtless stimulated the third thoracic (which is not usually regarded as belonging to the vasomotor field of the splanchnic) too short a time to obtain secretory effects.

This also alters my own belief that the cervical sympathetic also serves as a link between the pituitary body and the upper end of the sympathetic cord in the thorax.

All this accounts for the fact long ago recorded by von Bezold and Bensen,[63] that section of both splanchnics lowered the blood pressure as much as section of the spinal cord in the cervical region. It also explains why Strehl and Weiss found that, after removing one adrenal, the blood pressure could be lowered by clamping the suprarenal vein of the remaining organ, thus depriving the blood of any adrenal secretion, and that by releasing this vein the blood pressure was soon restored to its previous level.

Another organ closely related functionally with the pituitary body is the thyroid gland.

The secretion of the adrenals, by taking up oxygen in the lungs and carrying this gas to all parts of the organism, becomes the underlying factor not only of the pulmonary respiration, but also of tissue respiration. Last year I advanced the view that the purpose of the thyroid gland was to sustain the functional efficiency of the anterior pituitary body by means of its internal secretion. As such, therefore, this organ becomes itself associated with the general respiratory process. Suggestive, in this connection, is the fact that Andriezen,[64] after a study of the thyroid in lower animals and the results of its extirpation, reached the conclusion (although not aware of the nervous connection between the pituitary and the adrenals and the rôle of the latter in respiratory processes) that the morbid phenomena observed were ascribable to perturbations of the gaseous interchanges in the tissues. That the administration of thyroid extract enhances all oxidation processes of the organism, increasing the proportion of waste products in proportion, is now a familiar fact. The view that a functional—though undefined—relationship between the pituitary body and the thyroid exists, has long been defended by Stieda, Hofmeister, Gley and Andriezen, among others. Removal of the pituitary produces symptoms similar to those caused by extirpation of the thyroid, and the morbid symptoms of extirpation of this organ can be arrested by administering thyroid extract.

Again, as shown by Baumann, Hutchinson, Fränkel, Oswald and others, the active principle of thyroid extractive is an iodin compound. Considerable iodin has also been found in the pituitary body by Schnitzler and Ewald.[65] The presence in the latter organ of hypersensitive structures, and particularly of that recently described by Gentès, in which the end organs typify precisely those of olfactory end organs, adds further evidence to that already submitted by me, showing that it is through its secretion that the thyroid sustains the functional activity of the anterior lobe of the pituitary in which this structure was found.

Summing up the facts adduced, they seem to me to sustain the contention that the pituitary body, the adrenals and the thyroid jointly govern all oxidation processes, and, therefore, the functional efficiency of all organs.

If, as stated, the functions of the pituitary, the adrenals and the thyroid are interdependent—thus constituting what I have termed the "adrenal system"—impairment of the functional integrity of either one of them must morbidly influence that of the others. Overactivity of the thyroid, for example, by surcharging the blood with this organ's internal secretion, will overstimulate the pituitary body and through them the adrenals, thus causing the symptom-complex of general hyperoxidation: exophthalmic goiter. Conversely, lowering of the activity of the thyroid correspondingly lowers all oxidation processes, as instanced by the hypothermia of myxedema, cretinism, etc.

The bearing of these various functions on the convulsive disorders mentioned may now be outlined.

Munk provoked diaphragmatic tetanus when he stimulated the respiratory area adjoining the olfactory organs, the fibers of which traverse the central gray substance, and Cyon caused tetanic spasm on stimulating the pituitary body. Prus,[66] after a very large number of experiments, concluded that the spasmogenic impulses were not transmitted by the pyramidal tracts, but by others which he termed "extrapyramidal" and which passed below, i. e., by way of the midbrain or tegmentum—structures through which, I may add, the motor impulses from the central gray substances pass. Hering has since confirmed these results, and produced epileptic seizures after dividing both upper motor tracts, and it may be said that evidence to this effect is rapidly accumulating. Very recently Nino Samaja[67] showed by electrical stimulation of the region below the cortex, and decortication in newly born and adult animals of various kinds, that while in the higher adult mammals the motor cortical zone could alone evoke clonic convulsions, the lower brain was the source of stimuli which caused tonic spasm; and, furthermore, that while in man clonic convulsions were also of cortical origin, "the seat of tonic convulsions is exclusively basilar."

The predominant rôle with which the central gray axis (which extends from the pituitary body to the end of the spinal cord) is shown to be endowed in the foregoing pages readily accounts for these observations. Indeed, Magnan[68] caused epileptic seizures in guinea-pigs, pups and kittens deprived of their hemispheres. We can not conclude from this, however, that because Cyon caused tetanic spasm by exciting the pituitary body, the seizures in Magnan's animals were due to a similar cause. In the first place, as is well known, irritation of the fourth ventricle will cause convulsions, and, as shown by Brown-Séquard, Maier and others,[69] convulsions caused by various toxics, including strychnin, may include the lower limbs after division of the cord. In fact, Kussmaul and Tenner[70] found that removal of both hemispheres and the central gray substance, including the pituitary body, did not arrest convulsions caused by toxics.

It seems to me that we are dealing with two sources of convulsions: The first, a toxic in the plasma circulating in the nervous elements; the second, excessive activity in the pituitary body, leading to a correspondingly marked oxidation in all organs, including the muscles. The first is certainly pathogenic, while the most that can be said of the second is that it is an exaggerated manifestation of normal functional activity, and, perhaps, protective.

We do not have to go beyond the symptoms that follow extirpation of the organs involved to show that this is true. After removal of the pituitary body the symptoms are, in Schäfer's words: "1, Diminution of the body temperature; 2, anorexia and lassitude; 3, muscular twitchings and tremors developing later into spasms; 4, dyspnea." After removal of the thyroid in the monkey, "the most characteristic symptoms," says the same physiologist, are "muscular tremors passing gradually into clonic spasms, and finally into convulsive attacks

(tetany); there is also apathy and unsteadiness of gait, and, with the advance of time, the gradual supervention of a cretinic condition, together with a lowering of the body temperature and cutaneous sensibility." As to the adrenals, death occurs very soon after the removal of both organs, but long enough sometimes to indicate the kinship to the effects just outlined, including low respiration, anesthesia and hypothermia. "The animal lies on its side in a state of intense weakness," writes Auld, "is very drowsy, refusing to move, and may have convulsions."

In all three procedures we have diminution of the temperature and other signs of lowered oxygenation, and along with these, convulsions. We are evidently dealing, as a cause of the latter, with the first or pathogenic factor, i. e., a toxic. The identity of this toxic is readily accounted for: the avidity of the tissues for oxygen is such that it practically depletes not only the red corpuscles, but the plasma also, of this gas. Metabolism continuing in the tissues—though at a lower rate, as shown by the lowered temperature, the lassitude, the muscular weakness—waste products accumulate in the blood. Convulsions then appear, but as a terminal sign. Whether the supply of oxygen be reduced by removal of either of the three organs in question, or by withholding the air supply, as in asphyxiation, the one and same cause prevails, in my opinion, i. e., an accumulation of waste products in the blood plasma, including that which circulates within the neurons of the cortex and the central gray axis, and especially in their sensory terminals.

"In some animals, as in most carnivora," says Chittenden,[71] "complete removal of the thyroidal tissue is followed by a rapid development of symptoms indicating a marked irritation of the nervous and muscular systems, as manifested by tetanus, epileptiform convulsions, etc., and terminating in death."

Why do these products accumulate in the blood stream? The answer to this is afforded by the action of thyroid extract on the symptom-complex that thyroidectomy insures. Hoffmeister[72] found iodothyrin cuts short the symptoms that follow removal of the thyroid, including the convulsions. Baumann and Goldmann[73] showed that thyroidectomized dogs do not suffer from tetanic convulsions so long as adequate doses of iodothyrin are administered, and that they recur when the iodothyrin is withdrawn. Since, as emphasized by Hutchinson[74] and many other investigators, all the systemic oxidation processes are increased by the use of thyroid extractives, it is plain that oxidation is the underlying factor which prevents, either directly or indirectly, the accumulation of spasmogenic elements. Magnus Levy[75] and Scholz[76] found that thyroid extract increases the consumption of oxygen and the proportion of carbonic acid excreted. Mendel, Roos, Napier, Ord, Voit[77] and many other physiologic chemists have noted that it increased the excretion of the end-products of metabolism.

But the paramount point to us, therapeutists, is the fact that the convulsions ceased when under the influence of thyroid extract and the oxidation processes were brought to a sufficiently high level. Evidently the blood was purged of its toxic elements, the increased tissue respiration having entailed their conversion into benign eliminable products. In other words, the spasmogenic poison was overcome by the protective element of the organism, a product of its ductless glands. And this applies to any form of convulsion, whether it be due to accumulated waste products or to a specific toxic; whether, in a word, it occur during puerperal septicemia, epilepsy, hydrophobia or tetanus.

Now, what are the present mainstays in the treatment of these disorders? The bromids and chloral hydrate. "On mammals," says H. C. Wood, "the bromid acts very much as on frogs, inducing progressive paralysis, depression of temperature, and death by asphyxia when given in small poisonous doses." Of chloral, the same distinguished therapeutist says: "A most remarkable action of chloral is on the temperature; in this point all observers are in accord with Richardson of London, who has seen the temperature fall 6 F. in a rabbit. . . . Hammerstein has found that the fall of temperature is very rapid, 6 C. in an hour, and that it occurs in animals well wrapped up and laid in a warm place." If the protective, curative element in these dread diseases is hyperoxidation, what may we expect of induced hypo-oxidation? The mortality ratio of rabies, tetanus and puerperal eclampsia, treated on those lines, answers that question. These drugs reduce, it is true, the excitability of the sensory elements, but they aid the accumulation of the spasmogenic toxics by inhibiting the oxidation process through which these are destroyed.

Last year I advocated precisely the opposite course; lines of treatment which increase the functional activity of the adrenal system doing precisely what thyroid extract does after removal of the thyroid. Nicholson[78] has not only found that in puerperal eclampsia the normal enlargement of the thyroid—to which Lange called attention after examining 133 women—which betokens increased functional activity, was not present, but that the nitrogenous metabolism was lowered. He obtained excellent results by the use, with a pure milk, of 7½ grain doses of thyroid extract every three or four hours, and morphin (a drug which in therapeutic doses stimulates the adrenal system) as an adjunct. Now, if the adrenal system is involved in such processes, its general center, the pituitary body, should give evidence of excessive activity. In 1898, L. Comte[79] examined the pituitary body in a number of women who had died during pregnancy and found not only that this organ was hypertrophied in every case, but that the anterior lobe was alone the seat of the hypertrophy. P. E. Launois and P. Mulon[80] recently examined histologically the pituitary of two eclamptic women, each aged about 30, and were brought to conclude by histologic examination that during pregnancy the pituitary body gives evidence of marked overactivity.

This exemplifies, it seems to me, the condition involved in all toxemias attended with convulsions. The increasing tendency to use iodin, mercurial inunctions and other agents which tend powerfully to increase oxidation and general metabolism by enhancing the functional activity of the organism's protective system, seems to me, therefore, to merit encouragement.

The views advanced by me in January, 1903, in this connection have recently received a striking confirmation in England. A. E. Wright,[81] formerly professor of pathology at the Netley School, referred to the presence "in considerable quantities in the blood" of a secretion the source of which he deemed unknown, and of which he thought diphtheria antitoxin was the most familiar example. Believing that, as he says, "all the protective substances" in the cure of disease "were to be regarded as produced by internal secretion," he employed Koch's new tuberculin in various conditions, to induce the appearance in the blood of the "antidotal substances" referred to, and obtained what he terms "extraordinarily good results" in some thirty cases of various kinds. "Patients with tuberculosis recovered," he is quoted as saying, "if they produced enough of the internal secretion to render their bodies uninhabitable by the tubercle bacillus." In the light of my own views, the tuberculin used by Dr. Wright merely did what several of our familiar drugs can do, provided, however, they be considered, not as direct antagonists of the morbid process that may be present, but as agents which, once in the blood, enhance the activity of the body's autoprotective resources, through the most sensitive of its sensory organs, the pituitary body.

DISCUSSION.

Dr. Heinrich Stern, New York City—In the investigations of the adrenal system so-called, physiologic investigation is by no means everything. The views and deductions of Dr. Sajous are so comprehensive and so revolutionizing that the bulk of the profession can not follow him. A good deal of the apathy of the profession as regards the acceptance of the ideas advanced by Dr. Sajous is due to the ill will borne him as an independent thinker. Those really opposed to his views are the professional laboratory laborers whose sterility of ideas is proverbial. However, many of the views advanced by Dr. Sajous still lack experimental confirmation. Again, it was Blum who first noticed glycosuria after injection of adrenalin. As a matter of fact, this and similar experiments do not explain anything. Their importance is always exaggerated. Glycosuria may follow the subcutaneous or intravenous injection of quite a number of other animal products, or that of a variety of drugs. To single out adrenalin as a specific glycosuria-producing substance is, therefore, an illogical undertaking. Beside, the administration of adrenalin, as practiced by Blum, is just as often not followed by glycosuria as it is followed by it.

Dr. C. E. De M. Sajous—Dr. Stern overlooks the facts that I mentioned Blum first among the observers who had found that adrenal extract caused glycosuria, and that his experiments were confirmed in this country by Croftan and Herter. I can not say that I have to contend with any of the ill will on the part of the profession to which Dr. Stern refers. New lines of thought require time for their development, and mine can not be expected to form an exception. All I can assert is, that they would never have been advanced had I not been certain that they were poised on a solid foundation.

THE AXIS OF ASTIGMATISM.*

J. HERBERT CLAIBORNE, M.D.

NEW YORK CITY.

Twelve years ago[1] I presented some views on the axis of astigmatism. Those views consisted partly of propositions to be verified or denied by experience, partly of facts as developed in my practice.

I set forth the initial proposition that the axis of astigmatism does not occur at haphazard, that there is a regularity in its occurrence in a given eye, and that there is a certain definite relationship between the axes in two eyes when both happen to be astigmatic.

The experience of the last twelve years has amply verified both the propositions and the facts set forth at that time. This experience embraces 1,176 cases of astigmatism taken from my private practice.

I desire to state that I shall employ the nomenclature indicated by the trial frames ordinarily in use, in which the circle is divided into halves of 180° each, with the 0° starting on the right on both sides in the horizontal plane as one looks at the frame. (Fig. 1.)

I consider this method eminently simple and reasonable, and if it were adopted universally to the exclusion of all others it would add greatly to the accuracy of the surgeon and optician, and would make a prescription written in one country easily, quickly and accurately comprehended in all others.

Inasmuch as I have adopted this method, I shall not discuss that one by which the tilting of the upper or lower end of the glass toward, or away from, the median line is indicated. I consider the method open to many and obviously sound objections.

In order, therefore, that I may pass at once to the discussion of my subject, permit me to take up the consideration of the axis of that cylindrical glass in the various forms of astigmatism *seriatim*.

I shall use the term "axis of astigmatism" synonymously with the axis of the glass that corrects it.

ASTIGMATISM IN A SINGLE EYE.

1. Simple hyperopic astigmatism in a single eye.

In the great majority of cases the axis of this form of astigmatism is vertical—that is, 90°. If a deviation from this position takes place, it must be in the direction of the horizontal axis on either of the two sides of the vertical, and the first position assured by such a deviation is the axis 75° or the axis 105°, which in this case is a deviation of 15° from the vertical position. The next axis of preference is either 135° or 45° on the other side of the vertical.

Now, the point which I wish to emphasize is that these five position, 90°, 75°, 45°, 105° and 135°, are the positions of preference in hyperopic astigmatism. When other axes than these are found they are irregular and unusual, and are the exceptions that prove the rule.

The arc of 90° extending from 135° to 45°, I describe as the realm of hyperopic astigmatism.

In this arc, as stated, 90° is the most usual, 105° and 75° less, and 135° and 45° the least usual.

The percentage of irregularities in this realm will be referred to later.

The axis 0° occurs by exception, and has been called the axis against the rule. It should be called simply horizontal, for any axis that lies beyond 135° or 45° toward the horizontal plane, is against the rule. I would, therefore, suggest that the expression, "against the rule," in hyperopic astigmatism, be used to describe any axis that lies beyond 135° or 45° toward the horizontal plane. (Fig. 2.)

2. Simple myopic astigmatism in a single eye.

The axis of simple myopic astigmatism is, in the large majority of cases, horizontal. If the astigmatism selects a deviation from this axis, it selects the axis that is 15° from the horizontal on one side or the other; in other words, the axis 165° or the axis 15° is chosen.

The arc of 30° extending 15° to 165° I describe as the realm of myopic astigmatism.

In this realm the horizontal is by far the most frequent, and the axes 15° and 165° occur with nearly equal frequency.

---

[81] Wright: Brit. Med. Jour., March 19, p. 667, 1904.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

[1] New York Med. Jour., June 25 and July 2, 1892.

When, as in rare exceptions, the axis lies vertical, it is said to be against the rule. Whenever the axis lies beyond 15° or 165°, toward the vertical plane, it is against the rule. I, therefore, suggest that the expression, "against the rule," in myopic astigmatism be used whenever the axis lies beyond 15° or 165°, toward the vertical meridian.

The percentage of irregularities in this realm will be referred to later. (Fig. 3.)

3. Compound hyperopic astigmatism in a single eye.

Statements made with reference to the axis in simple hyperopic astigmatism, hold in compound hyperopic astigmatism, for obvious reasons.

4. Compound myopic astigmatism in a single eye.

The axes of compound myopic astigmatism are the axes of simple myopic astigmatism.

5. Mixed astigmatism in a single eye.

It may be broadly said that the rules which obtain in hyperopic and myopic astigmatism hold good when these conditions occur in the same eye, as in mixed astigmatism. The axis of the hyperopic astigmatism is restricted, as a rule, to the realm marked out for this error, and to the axes of preference in this realm. The axis of the myopic astigmatism is restricted to its realm and the axes of preference contained therein, so long as this is permitted by the axis of the hyperopic astigmatism. The two axes invariably, and of necessity, lie at right angles to each other.

If the hyperopic axis lies at 75°, the myopic axis will lie at 165°; if the myopic at 15°, the hyperopic will lie at 105°. If, however, the hyperopic axis lies at 135° or 45°, the myopic axis will be forced from its proper realm and will be compelled to invade the realm of the hyperopic axis. For example, if the hyperopic axis lies at 135°, the myopic will be at 45°, or *vice versa.*

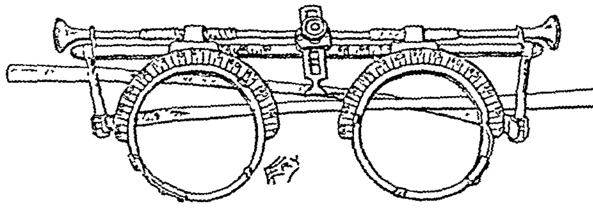

Figure 1.

The following are the regular positions of the axes in mixed astigmatism in a single eye. (Fig. 4.)

ASTIGMATISM IN BOTH EYES.

We come next to the consideration of the axis of astigmatism in each eye with relation to that of its fellow.

Before entering this subject, I would refer to the initial proposition relative to the definite relationship existing between the axes in the two eyes when each is astigmatic.

Experience has shown me that without a doubt the axes in the two eyes have a definite relationship to each other, and, indeed, this is necessary if the positions of preference in each eye separately be admitted or proved.

When the axes in the two eyes have the same position, I call them correspondent or in correspondence. If each be at 90°, they are correspondent. If each be at 180°, they are correspondent. When the axes lie off the horizontal or vertical and occupy the same position as indicated by the nomenclature of the half disc of the trial frame, they are no less correspondent, and it is when this phenomenon arises that the value of this nomenclature over the other is demonstrated. Suppose, for example, the axis in each eye is found to be at 75°, the axes will be tilted, the upper end of one toward the median line, the upper end of the other toward the temple. But the statement that the axes are "75° in correspondence," or simply the statement that they are both 75°, makes the facts perfectly clear.

When each axis is 135° or 45°, the bare statement of the fact is similarly clear.

At first sight the adjective, parallel, would appear, under these conditions, to be appropriate, but it would obviously be inadequate and inaccurate when each axis is horizontal or vertical. For, while they might be said, in the case of 90°, to be parallel, in the case of 180° or 0° they could not be said to be parallel; for, if each axis is continued toward its fellow, they will meet in the same plane and become coincident. The multiplication of terms is ill advised, and inasmuch as the expression, "in correspondence," covers all the cases cited above, I suggest this to indicate the fact that the axis of astigmatism lies in the same plane in the same meridian in each eye. I, myself, have used and taught this expression for the last twelve years.

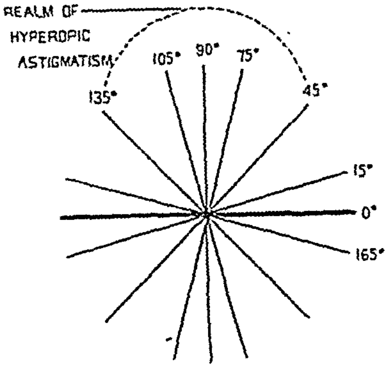

Figure 2.

1. Simple hyperopic astigmatism in both eyes.

In broad terms, the axes correspond or are at angles to each other. If, for example, the axis of one eye is vertical, that of its fellow is vertical. If the rare occurrence of the axis in the horizontal be found in one eye, the axis of the fellow is also horizontal. If the right axis be found to be 75°, the axis in the left eye is usually 105°. If, therefore, these two axes be prolonged upward and inward in straight lines, they will both converge toward the median line and intersect one another at the angle of 30.° (Fig. 5, B.)

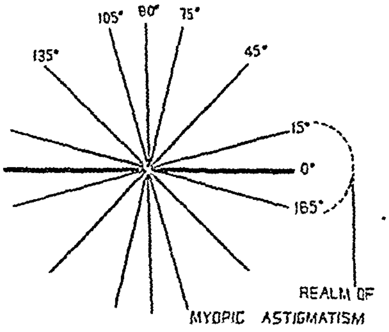

Figure 3.

If the right axis be found at 105°, the left will lie at 75°, and a continuation of these axes downward and inward, in straight lines, will cause them to converge toward the median line and intersect at the angle of 30°. (Fig. 5, C.)

If the right axis lies at 135° and the left at 45°, a *continuation* of these lines downward and inward will cause them to intersect at an angle of 90°. (Fig. 5, D.)

If the right axis lies at 45° and the left at 135°, they will intersect at the angle of 90°, if continued upward and inward.

These five positions are, as heretofore set forth, the axes of preference lying within the realm of hyperopic astigmatism; and the position of the axis in each eye relative to its fellow in the opposite, is the usual one. Nevertheless, it is possible for the axes in the two eyes to be in correspondence. This is exceedingly rare, but it nevertheless occurs.

The following correspondent axes of 105° occurred four times in 1,176 cases of astigmatism. (Fig. 5, G.)

The following correspondent axes, 135°, occurred once in 1,176 cases of astigmatism. (Fig. 5, H.)

Correspondence in 45° and in 75° did not occur at all in 1,176 cases.

It has been stated that the myopic axis may invade the realm of the hyperopic axis.

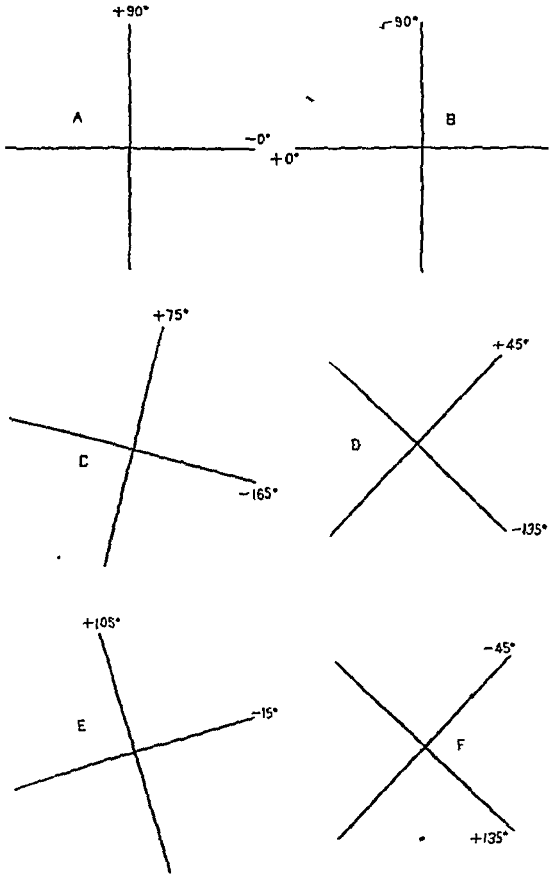

Figure 4.

The following case, which occurred once in the above-mentioned number of cases, is remarkable (Fig. 6):

2. Simple myopic astigatism in both eyes.

If the axis of one eye lies horizontal, the axis of the fellow is usually horizontal. If the axis of the right eye is 15°, the axis of the other is usually 165°, and if these two axes be continued in straight lines upward and inward they will intersect at an angle of 30°. (Fig. 7, B.)

It is possible, however, for the oblique axes to be in correspondence.

The following axes in correspondence occurred 3 times in 1,176 times (Fig. 7, C.):

Hyperopic astigmatism in correspondence invaded the myopic realm once in 1,176 times. (Fig. 8.)

The axes 15° in correspondence occurred twice in 1,176 times. (Fig. 7, D.)

At times the axes in each eye lie at 90°. (Fig. 7, E.)

There are three regular positions, then, for the axes in myopic astigmatism in both eyes, 180°, 15° and 165°.

When the axes are oblique they will intersect when prolonged toward each other at an angle of 30°.

3. Compound hyperopic astigmatism in both eyes.

The rules that have been drawn for the axes in simple hyperopic astigmatism in both eyes obtain for the axes of compound hyperopic astigmatism in both eyes.

4. Compound myopic astigmatism in both eyes.

The rules that have been drawn for the axes in simple myopic astigmatism in both eyes obtain for the axes of compound myopic astigmatism in both eyes.

5. Mixed astigmatism in both eyes.

In mixed astigmatism in both eyes the hyperopic axis is usually vertical in each eye, and the myopic axis is usually horizontal in each eye.

Matters, however, become somewhat complicated the moment any departure from the most usual position takes place in mixed astigmatism.

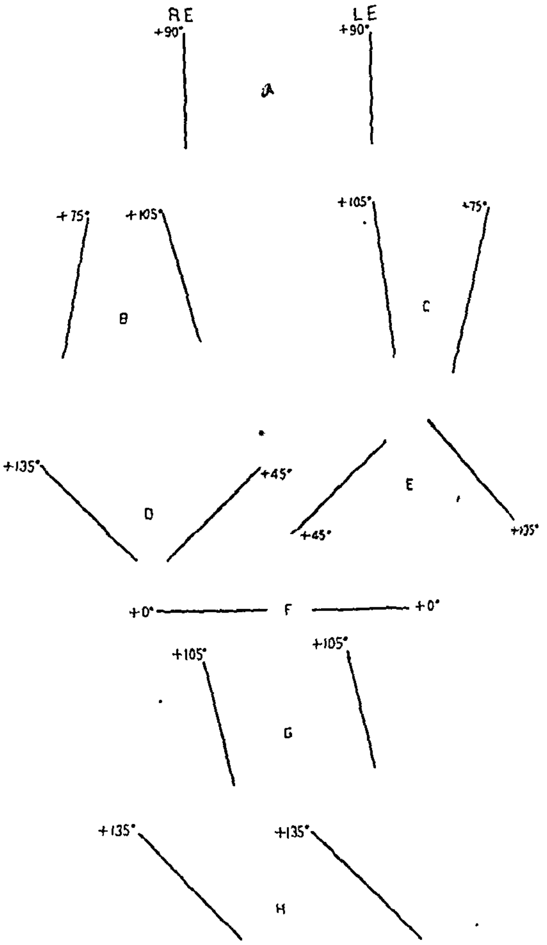

Figure 5.

The following are the usual positions of the axes in mixed astigmatism in both eyes (Fig. 9):

It is, of course, possible for correspondence to take place similarly in the two eyes. This, however, is so exceedingly rare that I found it but once in 1,176 cases. (Fig. 10.)

We come on now to the consideration of irregular cases—that is, those in which the axis occurred within the confines of its own realm, but at unusual positions, not the positions of preference.

Eighty of these irregular cases were found among 1,176 cases of astigmatism, .68 per cent.

These figures prove conclusively that there are axes of preference for hyperopic and myopic astigmatism within the realm proper of each, and amply justify the propositions and views set forth by me in 1892.

The percentage of irregularity (.68 per cent.) is so small, and the percentage of regularity, 99.32 per cent., so great, that a conclusive, definite statement is warranted.

IRREGULARITIES WITHIN THE REALM OF HYPEROPIC ASTIGMATISM.

The axis of 60° occurred 25 times in 80 irregular cases; that is, 31 per cent.

The axis 120° occurred 24 times in 80 irregular cases; that is, 30 per cent.

The axis 110½° occurred once in 80 irregular cases.

Myopic astigmatism once in the irregular cases invaded the realm of hyperopia; this axis was exceedingly erratic; it was at 70°.

With the exception of the just mentioned erratic axis of myopic astigmatism, it is shown by the above figures that only 49 cases of irregularities occurred in the realm of hyperopia, out of 1,176 cases, and that of these the axes lay: 25 at 60° and 24 at 120°. This shows conclusively that if the ordinary axes of preference in hyperopic astigmatism are not chosen, the axis 60° or 120° is preferred.

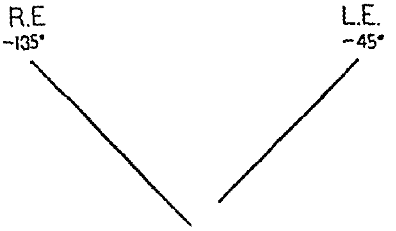

Figure 6.

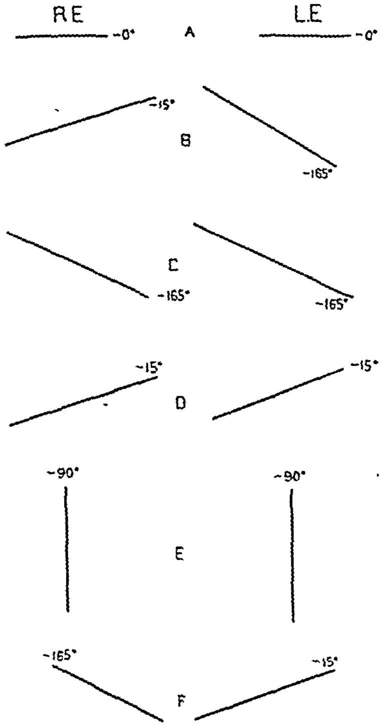

Figure 7.

IRREGULARITIES IN THE REALM OF MYOPIC ASTIGMATISM.

The axis 170° occurred five times in 80 irregular cases—that is, 6 per cent.

The axis 10° occurred once in 80 irregular cases.

The axis 2½° occurred once in 80 irregular cases.

It is conclusively shown by the figures that only 7 cases of irregularity occurred in the realm of myopic astigmatism, out of 1,176 cases, and that if the ordinary axes of preference in this realm are not chosen, 170° is preferred.

We have already pointed out the realm of hypermetropic astigmatism and that of myopic astigmatism. The areas occupied by these two realms, however, do not comprise the entire circle. For lying between 135° and 165° on the one side is an arc of 30°, and between 45° and 15°, on the other, another arc of 30°, which may be denominated the realms of neutrality, and which may be invaded by either the myopic or hyperopic axes. (Fig. 11.)

We shall regard first the axes which lie within the arc of 30° to be found between 15° and 45°.

Hyperopic astigmatism, with the axis at 30°, occurred fourteen times in the 80 irregular cases referred to, 17 per cent.

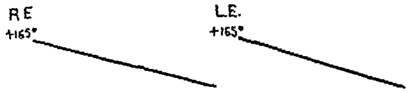

Figure 8.

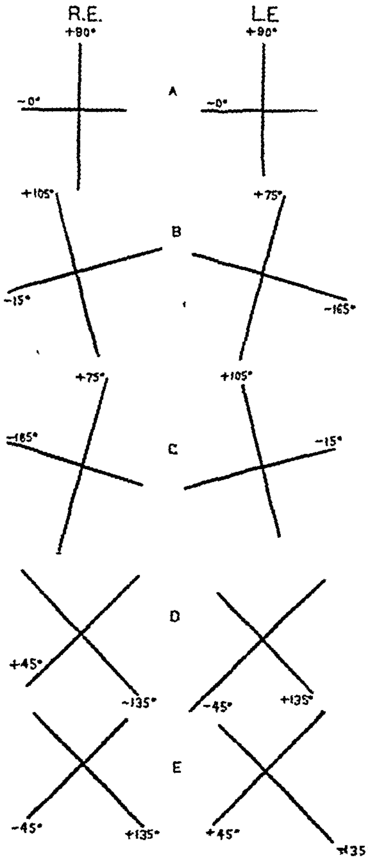

Figure 9.

Myopic astigmatism, with the axis at 30°, occurred seven times in the 80 irregular cases, 8 per cent.

Myopic astigmatism occupied the axis at 20° four times in the 80 irregular cases, 5 per cent.

The axis 30° and 20° were the only two axes selected in this arc of neutrality, hyperopic astigmatism occurring fourteen times at 30°, myopic astigmatism occurring seven times at 30°, and only myopic astigmatism occurring four times at 20°.

From these facts it appears that there are two axes of preference in this arc of neutrality, 30° and 20°, and that 30° is twice as usual in hyperopia as in myopia and that myopia alone occurs at 20°.

We shall now consider the arc lying between 135° and 165°.

Hyperopic astigmatism occupied the axis 150° seven times in the 80 irregular cases, 8 per cent.

Myopic astigmatism occupied the axis 150° seven times in the 80 irregular cases, 8 per cent.

Myopic astigmatism occupied the extremely erratic axis 155° once in these cases.

From the above it appears that there is only one axis of preference in the arc of neutrality lying between 135° and 165°, and that that axis is 150°.

The axis 155° occurred only once, while the axis 150° occurred fourteen times, being occupied seven times by myopic astigmatism and seven times by hyperopic astigmatism.

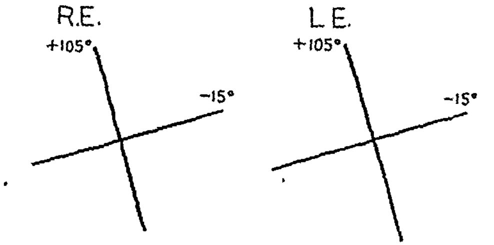

Figure 10.

No other axes occurred in the arc in the 1,176 cases of astigmatism.

It is interesting to note that correspondence occurred five times in the 80 irregular cases, 6 per cent., and in these five times 60° occurred twice, 30° twice and 120° once.

It has been stated that there is a regular relationship between the axes of astigmatism in the two eyes when the axes occupy the positions of preference in the regular realms of myopia and hyperopia.

It is interesting to observe that the same regular relationship exists when the axes are irregular, as, for example, in Figure 12. The intersection of these two axes form an angle of 90°. Again, in Figures 13 and 14, an angle of 60° is found.

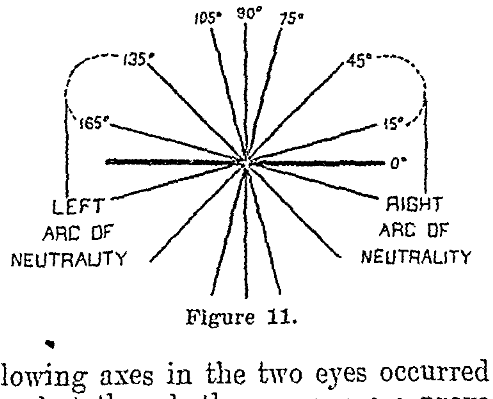

Figure 11.

The following axes in the two eyes occurred twice in 1,176 cases, but though these axes were proved correct time after time by separate tests of each eye, the patient in one case could not wear the glasses and was compelled to wear the axis at 180°. (Fig. 15.)

There were 1,042 cases of bilateral astigmatism. In 142 cases there was non-conformance with the rule in the relationship of the axes, 13 per cent. *Per contra*, there were 901 cases of conformance, 87 per cent. This percentage of conformance establishes the rule.

It is plainly shown by all these facts that when astigmatism occurs in the two eyes, the axes bear a definite relationship to each other, whether the astigmatism occurs in its proper realm, whether it invades that of its fellow, or whether it occurs in the realms of neutrality.

It is further shown that the axes in the two eyes when continued toward the median line, intersect each other at 30°, 60° or 90°, i. e., in the multiples of 30°.

The routine which I am accustomed to use in determining the quality, amount and axis of astigmatism, is to use skiascopy first, then the direct method, and finally the ophthalmometer.

In clinical work, and frequently in private practice, I use a modification of Placido's disc, constructed on the lines laid down above with reference to the realms of myopic and hyperopic astigmatism. I have employed the ophthalmometer regularly in private practice for eight years only. Antecedent to that time, I used it irregularly or not at all.

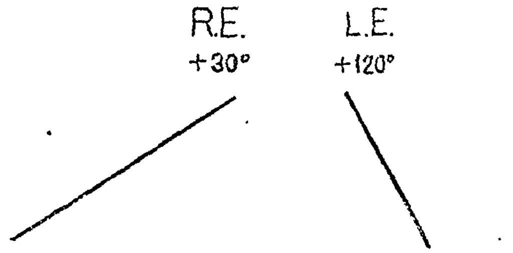

Figure 12.

I rely on the shadow test for the axis of astigmatism as confidently, if not more confidently, than I do on the ophthalmometer. The latter instrument frequently fails to give the exact axis as established by the subjective test, when the astigmatism is oblique. When, however, the axis lies horizontal or vertical, I have found the ophthalmometer true. All who use skiascopy know it is possible to see when the shadow is just off the vertical or horizontal, and when this is the case it may with reasonable certainty, be assumed to be at 75° or 105° in the case of hypermetropic astigmatism, or at 15° or 165° in the case of myopic astigmatism.

If the shadow moves in a plane more than 15° beyond the vertical or horizontal, it will be found, as shown by my statistics, in one of the positions of preference which lie beyond these planes.

I wish to state emphatically, however, that I consider the subjective test the crucial test, and I regard its decision as final.

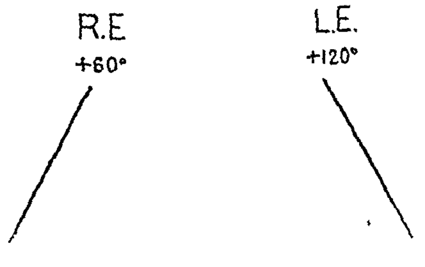

Figure 13.

When the patient is not intelligent enough to establish the fact conclusively, that axis is selected which is indicated by the sum of the evidence furnished by all the methods.

In using my modification of Placido's disc (Fig. 16) I use a + 4 D., held in one hand, behind the aperture.

CONCLUSIONS.

1. The axis of astigmatism does not occur at haphazard.

2. There is a realm of preference and there are positions of preference within the realm for hyperopic and myopic astigmatism, respectively.

3. The realm of hyperopic astigmatism is the arc of

the circle, inclusive of the axes, 45° and 135°, and the positions of preference in this realm are the axes 90°, 105,° 135°, 75° and 45°. The realm of hyperopic astigmatism is, therefore an arc of 90°.

4. The realm of myopic astigmatism is the arc inclusive of the axes 15° and 165°, and the positions of preference in this realm are the axes 180°, 15° and 165°. The realm of myopic astigmatism is, therefore, an arc of 30°.

5. There is a realm or arc of neutrality of 30°, lying between 15° and 45° on the one side of the circle, and 135° and 165° on the other.

The arc of 30° lying between 15° and 45° may be called the right arc of neutrality, since it lies on each side to the right as one looks at the spectacle frame.

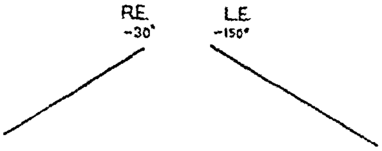

Figure 14.

The arc of 30° lying between 135° and 165° may be called the left arc of neutrality, since it lies to the left on each side as one looks at the spectacle frame.

Within the right arc of neutrality, 15° to 45°, the axes of preference are 30° and 20°, and 30° occurs twice as usual in hyperopia as in myopia, and myopia alone occurs at 20°.

Within the left arc of neutrality, 135° to 165°, there is one axis of preference, viz., 150°, and this occurs with equal frequency in myopia and hyperopia.

6 Of 1,176 cases of astigmatism, 80 cases were found in the realms of hyperopia and myopia in which the axes did not lie in the positions of preference. These are exceptional irregular cases.

The percentage of irregularity within the realms of hyperopia and myopia was 0.68 per cent.

Per contra, the percentage of preference was 99.72 per cent.

These facts establish the correctness of the preceding statements touching the positions of preference within the realms of hyperopia and myopia.

7. If the ordinary axes of preference in the realm of hyperopia are not chosen, the axes 60° and 120° are selected with equal frequency.

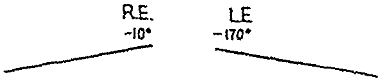

Figure 15.

8. If the ordinary axes of preference in the realm of myopia are not chosen, the axis 170° is selected.

9. Of 1,176 cases, 54 were found in which the hyperopic axis lay at 180°, .4+ per cent.

10. Of 1,176 cases, 21 were found in which the myopic axis lay at 90°, 1.8 per cent.

11. From these facts it is obvious that the hyperopic axis is found twice as frequently in the horizontal meridian as the myopic in the vertical meridian.

12. When astigmatism occurs in each eye, the axes bear a definite relationship to each other.

13. They may occupy the same position, in which case they are correspondent or in correspondence, or they may be inclined to the median line at a certain definite angle which is the same in each eye.

14. The angles at which they are inclined to the median line are 30°, 60° or 90°, or multiples of 30.

15. This obtains whether the axis lies in its own proper realm, in the realm of opposite quality, or in either of the realms of neutrality.

16. Of 1,043 cases of astigmatism in both eyes, there were 142 cases of non-conformity with the above statement, i. e., 13 per cent. *Per contra*, there were 901 cases in which there was conformity, i. e., 87 per cent.

These facts establish the correctness of the preceding conclusions touching the relationship of the axis in each eye to its fellow in the other eye.

17. There were 16 cases of correspondence all told, in 1,176 cases, 1.4 per cent. Of these 16 cases, 11 occurred in the axes of preference; of the remaining 5 cases, correspondence at 30° occurred twice, at 60° twice, and at 120° once.

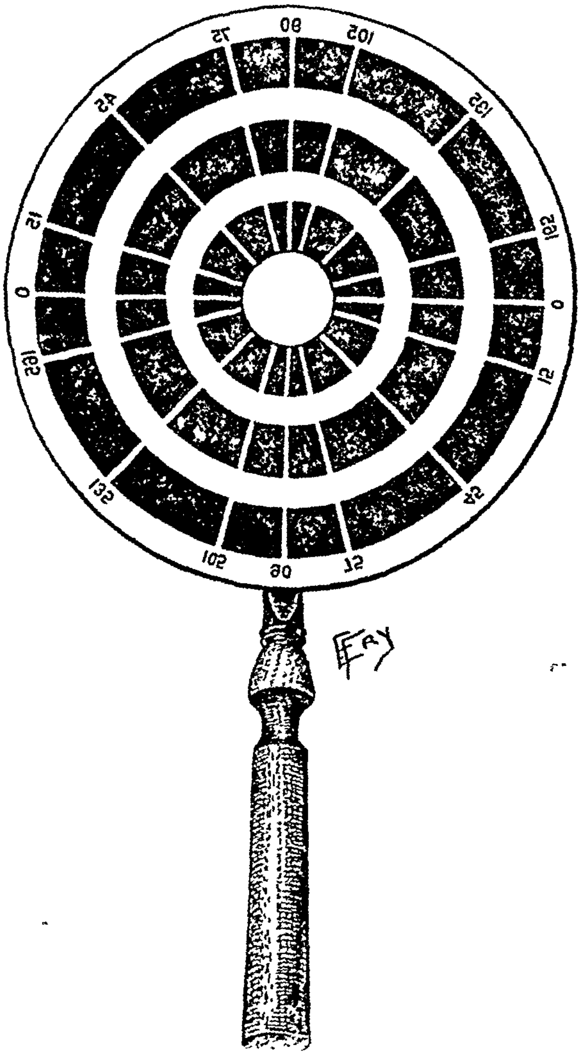

Figure 16.

18. The occurrence of the number 15, or its multiples, in the axis of astigmatism in each eye separately, as indicated in the positions of preference in every realm, and in the relationship of the axes in the two eyes toward each other, is remarkable, and warrants the conclusion that the axis of astigmatism does not occur at haphazard; that the law which governs it is a law of multiples, and that 15 is the common multiple.

19. The method of indicating the axis of astigmatism furnished by the ordinary trial frame in common use, is without doubt the simplest and most accurate, and should be universally employed.

THE RELATION OF CORNEAL CURVATURES TO THE REFRACTION OF THE EYE.*

MELVILLE BLACK, M.D.
Professor of Ophthalmology, Denver and Gross Medical College.
DENVER.

I have included in this report all cases of refraction examined under a cycloplegic that came under my care from December, 1901, to December, 1903. The errors of refraction were estimated in the usual manner with trial lenses. The instrument used in making the corneal measurements was the ophthalmometer of Chambers, Inskeep & Co. On the side of one of the recording wheels the curvature of the corneal meridians can be read off in millimeters. This instrument, so far as I know, is accurate. It does not measure corneal meridians whose radii of curvature are shorter than 6.85 mm., nor of those longer than 9.00 mm.

TABLE 1.

Radius of Corneal Curvature Measured in Millimeters.	Number of Meridians Found with This Curvature.	Number of These Meridians Found To Be Hyperopic in Refraction. 	2092	1273	507	312				

Reference to Table 1 shows that out of 2,092 corneal meridians examined, 1,273 were hypermetropic in refraction, 507 myopic and 312 emmetropic. It was found that the instrument measured all corneæ that came under my observation, except one case of conical cornea and one cornea examined soon after cataract extraction. Its field of measurement was found to be more than sufficient for all practical purposes. The table shows that of the 2,092 meridians examined none was found of a shorter radius of curvature than 6.85 and none longer than 8.75 mm.

Some explanation of my tables is necessary. The first column shows the radius of each corneal curvature as measured in millimeters. Columns 2, 3, 4 and 5 are self-explanatory. Column 6 is the total meridional refraction found to be hypermetropic, and is expressed in dioptries. Column 7 records the total refraction of the meridians found to be myopic. In Column 8 the aggregate amount of hypermetropia is divided by the total number of meridians recorded in Column 2. In Column 9 the same division is carried out with the myopic meridians. It may be asked why the aggregate hypermetropia was not divided simply by the number of meridians found hypermetropic, and the aggregate myopia by the number of meridians found myopic. If this had been done the number of meridians found to be emmetropic would not have entered into the equation, nor would we have the true average of ametropia of the total number of meridians with a given curvature. You will observe that out of 2,092 meridians examined, there were 168 meridians whose radius of curvature was 7.78 mm. This meridian stands about midway between the extreme curvatures. It was hypermetropic in refraction in 101 instances and emmetropic in 32. These figures record the greatest number of hypermetropic and emmetropic meridians. It will also be observed that the number of hypermetropic and emmetropic meridians recorded increases gradually from the center toward the top and bottom of the table.

TABLE 2.

Radius of Corneal Curvature Measured in Millimeters.	Number of Meridians Found with This Curvature.	Number of These Meridians Found To Be Hyperopic in Refraction.	Number Found To Be Myopic in Refraction.	Number Found Emmetropic.	Aggregate Amount of Hyperopia.	Aggregate Amount of Myopia.	Average Hyperopia.	Average Myopia.
9.00 to 8.80	....	....	...	...	......	......	....	....
8.75 to 8.60	2	2	...	...	6.50	......	3.25	....
8.55 to 8.41	37	28	5	4	49.00	19.00	1.33	.51
8.36 to 8.21	124	85	22	17	169.25	58.75	1.36	.48
8.16 to 8.00	237	158	49	30	224.75	146.25	.95	.61
7.95 to 7.82	434	305	65	64	337.75	111.50	.80	.25
7.78 to 7.66	491	309	94	88	427.50	222 00	.90	.45
7.62 to 7.48	380	229	92	59	208.75	163.25	.55	.45

7.31 to 7.19	74	30	33	11	30.50	106.75	.41	1.44
7.15 to 7.03	32	10	17	5	12.50	44.00	.39	1.37
7.00 to 6.85	12	....	12	...	......	31.75	....	2.64
	2092	1273	507	312				

Table 2 groups the meridians of the first table in fours. In this way the averages of hypermetropia and myopia are more striking. The longer the radius of corneal curvature, the greater is the average of hypermetropia, and the shorter the radius of corneal curvature, the greater the average of myopia. This is striking enough in Table 1, but in Table 2 the reduction in the average hypermetropia from the meridian of greater to that of lesser radius is very striking indeed. The average myopia gradually increases in the same ratio that the hypermetropia decreases.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June. 1904.

It seems to me that these 2,092 meridians examined serve to show conclusively that the radius of corneal curvature has a very marked influence on the refraction of the eye. I can understand how a great many cases of axial myopia that have reached a high degree of progression would upset such relations as shown in my table, but fortunately for my conclusions, we do not see very many such cases in our western country.

I regret that my table of statistics is not larger, and that I did not begin making record of the radius of the corneal curvature more than two years ago. I hope at some future time to report further on this subject.

DISCUSSION

ON PAPERS OF DRS. CLAIBORNE AND BLACK.

Dr. O. A. Griffin, Ann Arbor—I would add a word in explanation of why the realms of hyperopic and myopic astigmatism are quite constant. In my opinion, this is due to the fact that the shortest diameter of the orbital cavity is usually placed vertically, which would tend to make the vertical curvature of the cornea greater than that of the horizontal. This tendency is augmented by the constant pressure of the lids on the upper and lower margins of the cornea. If the orbital axis and palpebral aperture are placed obliquely, the pressure on the cornea will be correspondingly exerted with a resulting obliquity in the axis of astigation; but, inasmuch as this is not the rule, the axes are usually symmetrical and the vertical curvature of the cornea is greatest. Not infrequently asymmetry of the axes obtains its origin in asymmetry of the lenticular curvatures, as is shown by the fact that the axis as determined subjectively does not correspond to the ophthalmometric findings. That the axis of astigmatism is not constant should be remembered in ordering correcting glasses, especially when the axes are oblique and a subsequent check test is not made after a cycloplegic determination of the refraction which, in many instances, reveals a wholly different position of the axis. These changes may be due to a false position of the lens, produced by paralysis of the ciliary muscle or action of the obliques. In the latter instance change of axis is usually observed in those cases in which the axes are slightly inclined from the vertical or horizontal positions, when there is an effort on the part of the oblique muscles to make the axes correspond in each eye, thus finally producing hypertrophy of the acting muscle or insufficiency of its opponent. With constant use of correcting glasses, the hypertrophy diminishes with a subsequent change in the axis of astigmatism—thus illustrating the importance of always determining the condition of the ocular muscles and its effect on the refractive condition before prescribing glasses.

Dr. A. G. Bennett, Buffalo, N. Y.—I agree with Dr. Claiborne that there is a realm of predilection for the axis to fall in, but I think it must be taken with reservation because age has considerable effect. In a study I made last year of 7,665 eyes I took my cases and divided them into decades. I spoke of the axes as falling in the meridian of greatest refraction. I found that in the first decade it occurred in nearly 90 per cent. in what I called the vertical region, which takes in 25 degrees on each side of the absolute vertical. In the first decade nearly 90 per cent. were in this region and 4 per cent. only in the horizontal. In the next decade, from ten to twenty, the vertical axis prevailed in 77 per cent.; in the next, from twenty to thirty, in 75 per cent.; from forty to fifty, 54 per cent.; after the patients reach fifty the axis will not occur in the vertical region half the time; it is about 37 per cent. When over seventy I found only 29 per cent. vertical. This is true within certain limitations of myopia, but I do not find variations so pronounced as in hypermetropia.

Dr. G. C. Harlan, Philadelphia—With reference to the relation of the axes in the two eyes: A few years ago I had 500 cases collated from the Wills Hospital records and in 70 per cent. the axes were exactly symmetrical, and in 78 per cent. within ten degrees of exact symmetry.

Dr. J. L. Borsch, Philadelphia—I would like to ask Dr. Black to explain his modification of the Placido disc. I have been using the de Wecker keratometer and will briefly describe it, as it is the most accurate, simple and rapid means of ascertaining astigmatism, besides having the advantage of being very inexpensive, costing from $12 to $14. It consists of a black disc with a central perforation; on one side of the instrument are white strips that form a perfect square when the pointer indicates zero. These strips are so arranged as to overlap and are movable; on the other side is a register marked from 0 to 18 diopters and a pointer attached to a screw which moves the white strips. Around the central perforation in the disc is a brass circle marked in degrees from 0 to 180, and on the plate an arrow to indicate the axis of astigmatism. The disc is held in one hand at 30 cm. from the patient's face and he is asked to look into the perforation with one eye, the other being covered with the hand. The observer on looking at the patient's cornea through the perforation will see an image of the white strips; if they form a perfect square there is no astigmatism; if they form an oblong—turn the instrument 90 degrees—turn the screw until the strips form a perfect square and then read off the amount of astigmatism, the degree and axis.

Dr. J. H. Claiborne—My modification of Placido's disc is represented in one of the pictures. You simply observe whether the picture is round or oblong. The instrument which I show here is practically the same thing. I have termed these positions of preference. I judge about where it is by means of the reflection. The ophthalmometer is not an accurate instrument; it often misses the axis by 15 degrees, especially where the astigmatism is oblique. With this instrument and a convex lens I can tell the astigmatism within three-quarters of a diopter. That is the result of ten years' constant practice with the instrument. I think I have a little facility in the examination of refraction; I have this because I bear these outlines in mind. After using skiascopy and the ophthalmometer, I put the cylinder at the first position of preference and then in a few minutes, if necessary, run up all these axes. It follows the rules which I evolved about ten or twelve years ago and have proved to my satisfaction. Dr. Griffin says that after the mydriatic the axis may be different; of course, but the subjective post-mydriatic test is the final test in all these cases. Concerning the axes of neutrality I think there are axes within that arc that are chosen. I would like to have the section observe these things. My 1,200 cases proved it to me conclusively and I would like to have the corroboration of the members of the section. I am sure they are largely true, if not in the exact percentage I have found.

THE MECHANICAL TREATMENT OF HIP DISEASE.*

ADOLPH LORENZ, M.D.

VIENNA, AUSTRIA.

Gentlemen:—Your friendly greeting reminds me of the splendid time which it was permitted me to spend in your great, free country. As that period was the most beautiful in my whole life, I naturally am glad to be reminded thereof, and, before everything else, let me thank you for having brought to my memory those reminiscences of America. Indeed, as I look over this meeting I can once more feel myself back in that time when I was permitted to describe and demonstrate my bloodless orthopedic operations to large audiences of my American colleagues. My American brethren were indeed very amiable, but they also let me work very hard. I may say that never in my life have I labored as in America. It was there that I learned what it meant to lead a "strenuous life."

---

* Address delivered before the Anglo-American Medical Association of Vienna, 1904.

I have chosen as the subject of my discourse one which will, perhaps, be of especial interest to you, because the views concerning it in America are entirely at variance with our conception of the subject. But I must emphasize that my own point of view in regard to the question of the mechanical treatment of hip disease differs very materially, not only from that held by Americans, but also from that held by many Europeans. I must, therefore, be prepared to be opposed and contradicted by some of my orthopedic colleagues in Europe.

In order to be able to judge of the value of mechanical treatment of hip disease, it is very important, as well as instructive, to take a look at such cases as have never been treated mechanically. Such cases are by no means rare. How often, indeed, is complicated and costly treatment impossible on account of the poverty of the parents, or oftener, on account of the great distance to the place where such treatment is offered. No less frequently does it happen that the parents become wearied of the lengthy treatment and give it up, letting the disease take its own course.

These cases all find their way to the physician in the end; oftenest after the disease has as good as run its course. What is it that impels the patient, or his parents, to seek the physician? It is the contraction deformity, as a rule, the flexion-adduction contraction, the shortened leg that becomes troublesome on account of the impediment to the gait. I must openly admit that to me such patients are not only the most interesting, but also the most desirable. They cause neither worry nor difficulty; they suffer no pain, their treatment is perfectly simple, lasts but a short time, and is usually followed by excellent results.

The intra-articular modeling redressement, a central or a subtrochanteric osteotomy, according to circumstances, corrects the contracted position of the joint and improves the patient's gait, usually to his complete satisfaction. In such cases, therefore, we are not treating tuberculosis of the hip, but rather a condition subsequent thereto, namely, the coxitic contracture. I have followed, with greatest interest, those cases in which the course of the disease was not influenced by any physician's mechanical intervention.

The history of one of these cases is about as follows: Many months, perhaps one or two years, before the first onset of the disease, the child limps slightly for a time. Motion in one leg is guarded during walking, lameness appears soon after, or, indeed, it is often apparent toward evening, when the child had previously been quite active. The next morning no trace of lameness is to be noted. After such an attack of limping, there often ensues a period of quiescence, which may be of several months' duration. Then limping once more comes on, to again disappear. One might get the impression that a trick of the child was at the bottom of this temporary lameness.

The lay expression, "voluntary limp," seems to have its origin in this idea. We know that there is nothing more involuntary, that there can be no more absolute constraint than the limp of beginning coxitis. After a whole series of such periods of limping (coxitic attacks), lameness finally becomes permanent. At the same time, it is only rarely that the child manifests pain in the hip or knee. As a rule, the child is active during the day, and sleeps well at night. Gradually, however, the picture changes, the child becomes more careful in its movements, it runs and jumps about less, but can still walk without pain. After greater exertion, pain, which passes away, however, asserts itself, especially in the knee. For a long time the knee is considered the diseased part. By and by sleep becomes restless; the child cries out at times, hardly awaking, however, and if asked why it cries it can not give a definite answer. During the day the child is comparatively or perhaps completely quiet. Gradually the nights become worse, the child awakes screaming, cries for awhile, and then falls asleep only to awaken again with a cry. The following morning the child is comparatively lively, has no pain, and runs about, perhaps limping a little. Toward the end, the child screams more than it sleeps during the night, and is not entirely free from pain during the day, but still manages to hobble about.

After many months, the little patient finally is forced to remain in bed because he can no longer use the diseased leg. During several weeks the child endures severe pain by day and still more by night. At last, however, the condition improves. The child asks to leave the bed, and again begins to get about with the aid of a cane or crutch. In time the pain departs and the child is lively again. During the course of the disease a swelling might have been noticed, which sooner or later opened and discharged pus, or the region about the joint may never have shown any swelling or pus formation. Finally, the crutch is discarded, and the child once more learns to walk fairly well, usually treading on the front part of the foot. The period during which the child can not walk at all lasts from several months to a year, according to the nature of the case, but seldom lasts more than one year. Some exceptional cases never leave off walking at all.

Such is the history of an untreated case. On examination one finds the leg in marked flexion, adduction-contracture; at times the joint is ankylotic. Perhaps scars of sinuses or discharging sinuses are present; perhaps there has been no pus formation. It seems a certainty, to me, that cases, untreated as they are, do not arrive at abscess formation any oftener than those treated mechanically.

So far as the existing contracture is concerned, the capacity for walking remains; the firmer the contracture the better the endurance in walking. The bones are firm and capable of bearing weight; the muscles of the limb are comparatively well developed.

Thus, you see, apart from the contracture, the result of a case, thus spontaneously cured by Nature, is not a poor one. In fact, I believe it is a good one. It is true, moreover, that these never-treated children attain an independent, enduring gait more quickly than the mechanically treated coxitic patients. This is not to be wondered at when we consider the manner in which the strictly mechanical treatment is carried out.

A great number of physicians—and to these belong most of my American colleagues—consider it absolutely necessary to confine coxitic patients to bed for more or less time, and there to carry out the treatment by extension. Such bed treatment is protracted for a number of months or even years. Not until the more alarming manifestations have disappeared are the children permitted to get up. They then get an extension apparatus which fixes the joint and which takes the weight of the body off the hip joint.

Other physicians—to this class belong foremost the English physicians who came under the influence of

Thomas of Liverpool—do not consider extension necessary, but content themselves with removing the weight of the body. However, they hold the same views as the Americans in regard to bed treatment, systematically conducted. A third group of physicians—to this belong the Germans—lay no great stress on bed treatment, but are, for the most part, believers in the ambulatory treatment. In order to carry this out there is applied to the diseased leg, from the pelvis to the sole of the foot, a closely fitting apparatus, precisely constructed, which fixes the joint in the correct position, thereby holding it extended and excluding every contact between foot and floor. Provided with such an apparatus, the sick children may enjoy fresh air and sunlight, and are able to move about fairly well without suffering pain. They are rescued from the confinement to bed and the sick room, which, in itself, is always damaging to health. For the limb, the apparatus is preferable to bed treatment, while the whole organism has the benefit of light, sun and motion, and thus conditions are offered for better nourishment.

Opinions are at variance as to whether extension is absolutely necessary to keep the leg as quiet as possible or whether simple fixation is sufficient. The Americans, and the Germans no less, swear by extension; the English have almost entirely abandoned extension and carry out the treatment of coxitis by fixation alone.

My standpoint in this question is that extension is useful to a certain degree, but is in no case necessary. At any rate, the mechanical treatment of coxitis is extraordinarily simplified by omitting extension. In the last ten years I have used extension practically not at all.

Before describing my treatment I will try to delineate an average case of coxitis which, having been seen at the very beginning of the symptoms, has been treated in the most careful way by all the expedients of mechanical therapy.

Let us assume, for example, that the child in question had been treated from the start by extension in bed for a considerable period which fixed the joint, not only taking the weight off the leg, but also extending the limb and which was worn day and night; say that this treatment has been carried out for all the years which the disease lasted.

We will assume, for the sake of simplicity, that the case was a mild one and that no pus formation had taken place. The pains were slight all through; night cries occurred, to be sure, but they were never bothersome. The child could always move about, with the exception, perhaps, of a longer or shorter period of especial sensitiveness. Accordingly there can be no doubt that this strict mechanical treatment has materially influenced the course of the wearisome disease. Now, to continue with this case, let us remove the "Hülsen-Apparat" and examine the position of the joint and the condition of the leg.

We probably find the joint in good position; perhaps there exists a very slight degree of adduction and flexion, or the joint has an apparent tendency to assume this position after the apparatus is removed. The joint is movable within a very small arc; there is always more or less shortening. On the whole the result of the examination of the joint is favorable.

Now let us look at the leg itself, and we will find it very much emaciated; the muscles flabby and without power; the knee joint has become lax under the long-continued influence of extension. The whole leg appears as a loose wobbling appendage of the trunk. Experience shows that the bones of such a leg are brittle and fragile. If we investigate the independent function of such a leg, there is shown an absolute inability to support, unaided, the weight of the body even for a moment.

This unfitness for function is not caused by pain, but is due to the extreme atrophy of the muscles and bones. Without the apparatus the patient is absolutely unable to walk even one step. He has become a slave to his machine or his crutches. This state of affairs after a while becomes unbearable to the patient. Finally he rids himself of the machine and is satisfied if he is able to walk independently; whether it be poorly or well; if he only does not have to resort to "his machine" again. Should such a patient have learned to emancipate himself from his "Hülsen-Apparat," then in nine out of ten cases an adduction contracture will have supervened in the course of a short time. I will even go so far as to state that this contracture must follow for obvious reasons, unless the patient takes special precautions against it.

If we now compare the two cases, the one which had no mechanical treatment and the other which was treated by the most careful mechanical method, we are forced to acknowledge that, in the latter case, the end result of our efforts of years is disproportionately small. The only noticeable advantage of this strict mechanical treatment is probably a diminution of the coxitic pain. But this is counterbalanced by the great discomfort occasioned the patient by a narrow, tightly fitting apparatus.

The course of the disease is not shortened by the strictest mechanical treatment, the frequency of abscess formation is hardly lessened, whereas the leg will unquestionably remain unfit for independent functional use for a much longer time than if the mechanical treatment had never been used at all. Another so-called advantage is the good position obtained, but this prevails only so long as the apparatus is worn. Let the patient discard the same and he will not often escape the resulting contracture caused by the walking. The advantages thus gained, therefore, are certainly problematic.

The disadvantages which go hand in hand with this extension treatment are very real. The shortening due to lack of growth must necessarily be greater, as the limb is excluded from motion for years. For the same reason the bones will be more brittle and incapable of weight-bearing than if no treatment had been carried out. The muscles of the whole limb are completely atrophied and functionally powerless. Moreover, the knee joint, which had no share in the disease, has suffered from the strict mechanical treatment; it has become loose and unstable and too weak for any function. These consequences, following strict mechanical fixation and extension treatment, arise from the fact that the limb has continually been restrained from use for a period of years. The child is almost in the position of one whose leg is altogether wanting as a result of an amputation at the hip joint.

Absolute functional restraint, continued for many years, is bound to be avenged and does the limb more harm than the disease of the hip joint itself. If, therefore, one compares the two cases referred to above, the one never treated mechanically and the other treated mechanically, in the most painstaking way, it is manifest that the first patient got off better than the latter. Perhaps the first patient has suffered a little more pain, but he has regained the independent use of his limb more rapidly. My view as to the mechanical treatment is that it does too much; it goes too far; it is an overtreatment, which, beside its few advantages, also entails unnecessary damages. No one can criticize the mechanical treatment because it has little effect on local tuberculosis. To cure tuberculosis we will require a serum, which up to the present has not been obtained. But we have a right to demand from mechanical treatment that it allow the general health to be bettered in order to influence the tuberculosis in an indirect way. Beside this we may also demand that the capacity for active locomotion on the part of the patient be guaranteed without the aforementioned after effects of mechanical overtreatment. Any one who has watched coxitis cases which have healed without the intervention of a physician, must finally arrive at these conclusions. From my observation of Nature I have formed my own mechanical treatment. This observation of Nature shows that the diseased joint is sensitive to weight bearing only during a relatively short period of time. During the far greater part of the disease the joint is practically not sensitive to weight bearing. Observation of Nature shows further that the diseased hip joint is extraordinarily sensitive to motion for nearly the entire duration of the disease. Every case not treated mechanically offers evidence for this assertion.

On this observation, my simple mechanical treatment is founded. This consists in obtaining the greatest possible security against movement in the joint, that is, the best possible fixation. I apply no extension, but in extreme cases use suspension for the time being. In most cases it is sufficient to protect a leg, which is sensitive on bearing weight from the shock of the weight. The object of this "physiologic mechanical treatment" is that the diseased joint is sufficiently protected without excluding from function the rest of the limb, which is otherwise healthy. On the contrary, the limb should fulfill the function of weight bearing during the whole course of the disease, regulated according to the amount of sensitiveness at any given time.

The physiologic mechanical treatment consists, in short, of the following measures. During the abduction period of the disease the joint is slightly or not at all sensitive against pressure. Therefore, during this stage, which lasts many months, perhaps a year or more, I simply fix the joint in its pathologic position by applying a firm plaster dressing which is renewed every three or four months. The knee joint remains free and the lower part of the leg is accessible to massage. The skin may be kept clean and healthy by means of a scratching band under the plaster. This fixation protects the joint against motion, especially at night, when the reflex muscle spasm is lessened. During weight bearing the pain is relieved. On the healthy side the shoe is raised to equalize the abduction lengthening. A plaster cast fulfills the purpose of rigid fixation better than a removable "Hülsen-Apparat," made of leather, because the elasticity of the latter allows the joint too much excursion.

With a cast of this sort the child goes about as long as treading on the limb is painless. If walking causes pain I fasten a leather splint to the lower end of the plaster which embraces the leg and foot and which is jointed at the knee and ankle. Thus in walking, the jar is intercepted by the steel sole piece of this lower leg splint, and is transferred to the apparatus, diminishing to such an extent that no pain is brought about. In cases where great sensitiveness prevails, the steel sole is placed somewhat lower so that the leg is in suspension in the apparatus. .Extension is superfluous. As soon as the sensitiveness to weight bearing ceases I give the lower leg its freedom again. In place of the plaster cast, a removable leather splint is applied which embraces pelvis and thigh. One may now begin with massage of the thigh and commence active abductive movements, always with caution, however. It goes without saying that no pain should be caused by these attempts to regenerate the pelvic trochanteric muscles. The exercises used in after treatment should confine themselves to active and passive abduction movements and to passive extension of the joint.

This set of gymnastics is for the purpose of counteracting the flexion-adduction contracture and to give the joint the position of extension as in standing; I call this position *"indifferente streckstellung."*

The joint is never moved in the sense of flexion, or in any other direction than mentioned above; no advantage is given the patient by a very movable joint. Our everyday experience shows that the looser and more movable a healed coxitis joint is, the worse it functionates. Exhaustion quickly supervenes which is augmented to actual pain, loose joints are easily traumatized and readily subject to accidental violence.

Seeing that the bones constituting the hip joint have usually undergone anatomic changes, and that the muscles about the joint are usually insufficient and powerless to properly support the affected joint, it is my opinion that the goal to be striven for in the treatment of coxitis is the position of "indifferent extension," with as much rigidity in the joint as possible, in other words, bony ankylosis of the hip in the indifferent position.

Bony ankylosis is not subject to traumatization, muscular insufficiency is harmless because muscular power is no more required and the danger of the "flexion-adduction" contracture is past.

Patients with such a result of treatment hardly limp at all and are not easily tired.

It is not in our power to modify the course of a case of coxitis that we may be sure to obtain bony ankylosis.

As it was not my place to talk of the operative treatment of hip disease, I have chosen for example cases without pus formation, and ones which could never have offered an indication for operative interference.

CONCLUSIONS.

In conclusion I wish to review in a few words the principles of the physiologic mechanical treatment of coxitis.

Knowing that mechanical treatment is unable to attack the disease (tuberculosis) itself, it must be constituted so that it is ambulatory, so that it allows of a certain freedom of locomotion and the enjoyment of fresh air, thus improving the general health of the patient. This mechanical treatment should not degenerate into an overtreatment, and must not lead to the result that the remaining healthy portion of the leg becomes withered and incapacitated for function.

I call the above described manner and means of treatment the physiologic one because it permits the physiologic function of the leg.

I believe I may assume that you, my honored colleagues, will take great interest in this, my conception of the principles of the rational treatment of coxitis, as these principles differ essentially from those generally accepted in your country. I can recommend my method of treatment, as it is much simpler than all others, and can be used by every physician in the land.

Perhaps I may offer as further recommendation that in fifteen years' experience this treatment has proved itself the best. I believe the simplicity of the method will find favor in the eyes of the practical Americans, and I would consider myself fortunate if I dared to hope to see my views planted in American soil by one or another of my honored colleagues.

THE MANAGEMENT OF PRISON TUBERCULOSIS,

WITH THE AID OF TUBERCULIN AS A DIAGNOSTIC AGENT.*

JEWETT V. REED, M.D.
Johns Hopkins Hospital
BALTIMORE.

The object of this paper is not to give any new facts in regard to tuberculosis or the use of tuberculin, but merely to give the methods used and results obtained in an attempt to combat the spread of tuberculosis from one point of this many-sided question, and in the hope that the suggestions here given will lead to similar work in other institutions of the kind. The question is not one that concerns the welfare of the inmates only, but the community at large. Men who are perfectly well, on entering these institutions, run a greater risk of contracting the diseases than if they remained out, and on leaving the institution a few years later become additional foci of contagion in other communities.

The following work was carried out in the Indiana Reformatory by Dr. H. C. Sharp, physician and surgeon in charge, and myself, during the summer of 1903. The reformatory, which is practically a penitentiary, averages about 950 male inmates of ages varying from 17 to 35 years, whose sentences are from one to twenty-one years. Those inmates who are not employed in the services of the reformatory are contracted out to several manufacturers whose plants are within the walls.

Tuberculosis has always been the chief cause of sickness and death in the institution, the form in which the disease most often manifests itself being the pulmonary and glandular type In many of these cases the diagnosis of tuberculosis was evident, but in a large group of men who complained of cough, expectoration, pains in the chest, gastrointestinal disturbances, weakness, etc, a positive diagnosis was difficult to obtain.

The problem before us was: 1, To diagnose every case of tuberculosis; 2, to separate the tubercular from the non-tubercular, and to take every precaution for the prevention of the spread of the disease; 3, to give those suffering from the disease the best treatment available.

In order to obtain a diagnosis in all cases, it was necessary for every man in the institution to receive a physical examination, and the first question to arise was in regard to the examination of the sputum for the tubercle bacilli. If this were carried out it would mean a task too great for practical purposes, and moreover, a certain number of very early cases might be overlooked in which tubercular sputa had not begun to appear, and also in cases where tuberculosis existed in other parts of the body. Therefore, we made no routine sputum examinations, but relied altogether on the administration of tuberculin to give the diagnosis in all doubtful cases. Many cases definitely tubercular, who were not running an elevated temperature, were given tuberculin in order to corroborate our results.

To begin with, every man in the institution was examined as follows: He was asked how he was feeling at the present time and when he was sick last. The following questions referred to the past as well as the present regarding pain, pain in the chest cough, expectoration. bloody expectoration, hemorrhages, night sweats, loss of weight and strength, pain in stomach, indigestion and condition of bowels. He was stripped to the waist and examined for enlarged glands, symmetry and expansion of chest, vocal fremitus, percussion and auscultation over the apex, back and front of chest. If any of the above symptoms were present, or if any one sign of pulmonary disease was found, no matter how slight, such as change in pitch or quality of note, harsh breath sounds, râles or prolonged expiration, the man was put on the list to receive the tuberculin test, and notes were kept as to the conditions found In taking the above history the question of sputum was found to be very unsatisfactory. In this part of the country almost everyone suffers more or less with nasopharyngeal catarrh, and the average man found difficulty in telling whether it came from his lungs or his pharynx. As the great majority of men examined gave a history of expectoration, the above was not

*Temp had been subnormal so that the rise obtained was over 2° associated with febrile symptoms taken into consideration unless it had at some time been bloody.

---

* Under the direction of H C Sharp physician and surgeon of Indiana Reformatory

Before starting the tuberculin test it was thought best to experiment with the dosage. The dose for diagnostic purposes was from 5 to 10 milligrams.[1] The larger dose was first tried, diluted in 1 c.c. of water, on a patient with definite tubercular adenitis, and for a control test another man, who was apparently perfectly healthy, was chosen to receive the administration at the same time. The former gave a typical tuberculin reaction with a rise of temperature of 104 degrees, while the latter felt perfectly well and his temperature remained normal. Other tubercular patients were tested with smaller doses of tuberculin, but the reaction was not so definite as when the 10-milligram dose was given; therefore, this maximum dose was employed throughout the series of tests.

In giving the tuberculin test nineteen men were tested at a time. They were taken into the hospital and a one hour temperature record was taken for about 36 hours so that a morning and evening temperature could be recorded. If any of the men were running an elevated temperature the test had to be postponed until it became normal, the tuberculin reaction being valueless unless given during a period of apyrexia. After the temperature record had been taken for the proper length of time 10 milligrams of tuberculin diluted with 1 c.c. of distilled water was injected deep into the left deltoid, the skin having been previously washed with soap and water, ether and alcohol. The injection was made at midnight so that the reaction could be watched on the following day.

Out of the 965 men in the institution who received a physical examination, 24 were found to be definitely tubercular and were not tested with tuberculin. Two hundred and seventy-eight men gave either one or many of the symptoms or signs of tubercular disease and received an injection. Of course, all of these were not thought to be tubercular, but by testing every suggestive case, no matter how slight his symptoms or signs, seemed to be the only sure way of picking out every case of tuberculosis. Out of this total number tested, 102 gave a definite tuberculin reaction, a definite reaction consisting in a rise of temperature two degrees above the maximum temperature previously recorded.

GROUP 2.

Those giving both symptoms and signs suggestive of pulmonary tuberculosis.

---

[1] The product used was the Mulford tuberculin. (It is necessary to mention this, as the dose varies greatly with the product used.)

accompanied with at least one febrile symptom, such as chill, headache, pain in back, etc.

These 102 men who gave a positive reaction may be divided into the following groups:

Group 1.—Those giving symptoms of pulmonary tuberculosis, but in whom no physical signs could be obtained after repeated examinations made before, during and after the tuberculin reaction.

Group 2.—Those giving both symptoms and signs of pulmonary tuberculosis.

Group 3.—Those without symptoms and whose only sign was enlarged glands.

Group 4.—Miscellaneous cases.

In this first group of 59 cases, 41 gave a history of cough, 36 gave a history of the sputum being bloody or blood tinged at one time or another, 33 of pains in some part of the chest, 15 of night sweats, 13 of chronic gastrointestinal disturbances and 11 gave a history of loss of weight.

It will be noticed that several of the maximum temperatures recorded are only between 100 degrees and 101 degrees, and the objection might be raised that this elevation is not sufficient to contribute a definite tuberculin reaction. It was a curious fact that the great majority of the men ran a temperature of about 1 degree below normal, for which we could find no explanation. However, a rise from this subnormal temperature to 100 degrees gave the required amount to constitute a reaction. As mentioned above a positive reaction consisted of a rise of temperature 2 degrees above the maximum temperature previously recorded, associated with at least one febrile symptom.

GROUP 3

Those where only signs of tuberculosis was enlarged submaxillary or cervical glands

Number of Convict.	Local Reaction Tender and Painful Glands.	Temperature of Reaction	Maximum Temp Hours after Injection

Total, 10.

Ten out of the number tested gave a slight rise of temperature, but not enough to constitute a definite reaction. In these a second injection was to be made at a later time, a report of which has not been made.

SUMMARY.

From the above results we feel very strongly that as a diagnostic agent tuberculin is of great value, not only in surgical tuberculosis, but in the early pulmonary form, where the finding of the tubercle bacilli in the sputum is very difficult or even impossible. In none of our cases, whether a positive reaction was obtained or not, did we find any ill effects following the administration of tuberculin, and this corresponds with the results of others, showing that the danger from the use of tuberculin is practically *nil*.

The result of our examination of 965 inmates showed 24 to be in an advanced stage of tubercular disease, and 102 who gave a definite tuberculin reaction, making a total of 126, or nearly 13 per cent.

PROTECTION OF THE NON-TUBERCULAR.

The next question was the protection of the non-tubercular, and the method of treatment of those infected with the disease. In regard to the prophylaxis our plans were as follows: The tubercular were separated from the non-tubercular by giving them a separate cell house and having them eat at separate tables. Receptacles for sputum containing sawdust dampened with a solution of crude carbolic acid, were placed in convenient locations throughout the grounds and shops. The dust about the grounds was done away with by sprinkling once a day. All sweeping in the cell houses and halls was done after first sprinkling sawdust wet with a solution of crude carbolic acid. This gave the whole place a strong odor of carbolic acid, but it is much more agreeable than the musty and dirty odor that formerly prevailed.

TREATMENT OF THE TUBERCULAR.

As to the treatment of the tubercular, those who were able to work were given an occupation suitable to their condition, while those too weak to work were given benches in a sunny part of the grounds where they could sit out of doors all day. All who were able were compelled to take regular exercise. Better food was supplied, and drugs administered such as cod liver oil, syrup of the iodid of iron and others as the case required.

9 cases total.

The therapeutic use of tuberculin has not yet been tried, but as to its value one case is very suggestive. Convict No. 3.756 (see chart of Group 2), who had suffered with bilateral pleurisy with constant and severe pain for two months, on receiving tuberculin, gave a reaction of 105.4. A few days later his pain was very much better, and six weeks later he said that the pains seldom bothered him, and he was feeling better in every way. However, a friction rub still remained.

CONCLUSIONS.

A year has now passed since the above work was done, and while we do not possess accurate statistics as to the number of inmates afflicted with tuberculosis at present in the institution, many facts go to show that there has been a decrease in the disease. During the year ending Aug. 1, 1904, there have been ten deaths from tuberculosis, which contrast favorably with the eighteen deaths that occurred the previous year. After making our tuberculin tests we found that the great majority of men who gave a reaction were those who were constantly coming to morning sick-call. During the past year the total number of inmates attending sick-call has been 40 per cent. less than the year before.

These few facts are enough to convince us that we are working in the right direction toward the management of prison tuberculosis, and we feel that the results thus far obtained fully repay us for our work.

TONSILLECTOMY, THOROUGH, PAINLESS AND SAFE.*

E. FLETCHER INGALS, M.D.
CHICAGO.

"What is worth doing at all is worth doing well," is a truism especially applicable to surgical procedures, for no operation should ever be undertaken excepting for the patient's best interests. We are all searching, therefore, for something that is better, whether it be new or whether it be simply a modification of the old. That the ancient operation for tonsillectomy is susceptible of improvement goes without saying when we consider some of the important conditions and when we witness some of its lamentable results. An unusual case which recently came under my observation induces me to bring up again this well-worn subject in the belief that there are many surgeons, even among laryngologists, who are not familiar with the technic of an operation that to me appears more thorough and much safer than the methods generally adopted.

The case referred to was that of a gentleman about 30 years of age who had suffered from frequent attacks of severe tonsillitis and in whom both tonsils were enlarged to the size of a small English walnut. From the history there was no doubt of the desirability of removing these glands, but on inspection I discovered on both sides large branches of the carotid artery pulsating at the base of the tonsil immediately beneath the mucous membrane, so that the operation with a tonsillotome, which might have been easily done, would have been attended with great risk; whereas the operation that I have in mind and that I prefer, for nearly all cases, could have been done with safety.

In any case of hypertrophy of the tonsils the questions to be considered are: Is an operation necessary? And, what operation would yield the best results in this particular case, with the minimum amount of danger and discomfort to the patient?

In the great majority of cases in which the tonsil is not larger than an almond, provided it is not subject to frequent acute attacks of inflammation, no operation is desirable; but in many cases tonsils even much smaller than this by reason of acute attacks are a source of danger and of great discomfort to the patient; therefore, their extirpation becomes important. There are some tonsils even larger than this that give the patient no inconvenience and that never will become a source of any considerable danger; but in the majority of cases these hypertrophied glands, because of their liability to infection and acute inflammation, are a constant menace and should, therefore, be removed.

In many cases the so-called submerged or buried tonsil is scarcely perceptible on inspecting the fauces when at rest; but they are rolled out so as to show considerable dimensions with the act of retching. Whether these be small or large, if subject to frequent acute attacks of inflammation, they should be removed.

In children we may reasonably expect hypertrophied tonsils to gradually atrophy and disappear before puberty, but it should be remembered that in the meantime they offer an open portal for the entrance of numerous germs of disease, and in the majority of cases they are associated with hypertrophy of the pharyngeal or Luschka's tonsil, with all its painful results; therefore, when a child has suffered two or three attacks of acute tonsillitis, whatever the size of the glands, it is usually best to advise their removal.

The operation to be selected necessarily depends on various conditions which may be present in individual cases. The old operation performed by seizing the tonsil with a vulsellum forceps and dissecting it out with a bistoury is now seldom employed, but it would undoubtedly yield better results than frequently obtained from some more modern methods. An operation by means of some one of several good tonsillotomes is best in adults, and sometimes also in children in those cases where the tonsil is not adherent to the anterior pillar of the fauces and when it is of such form and in such position that it can be readily engaged and thoroughly removed; in children, in the majority of cases, Luschka's tonsil is also enlarged and should be removed at the same time, which fact may induce us to adopt some other operation. Furthermore, we should not forget that the fright and pain to the little one caused by tonsillectomy is often fully as great as that an adult would suffer from amputation of the arm.

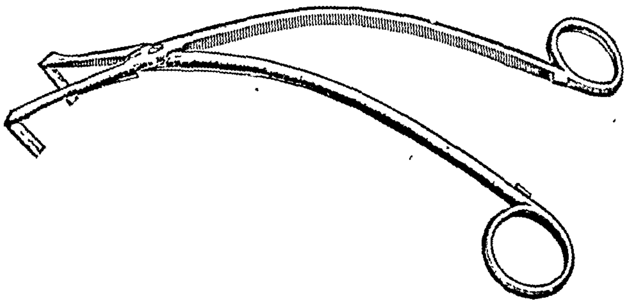

Fig. 1.—Tonsil separator.

In cases where the tonsil is hidden by the adherent anterior pillar of the fauces, a thorough operation is impossible with the ordinary tonsillotome unless the gland is first lifted out with forceps, and then serious hemorrhage is likely to result either from division of some large blood vessel within the tonsil or from cutting the anterior pillar. In these cases the glands may be cut out with biting forceps, but this operation is peculiarly liable to cause serious bleeding. In such cases we often resort to repeated cauterization, with gradual destruction of the gland rather than incur the dangers of tonsillectomy. Such cauterization, when properly performed and when the gland is not large, usually yields satisfactory results. It has also been recommended to dissect out these glands with the galvano cautery, but the large area that is burned in this operation causes much pain and such extensive cicatrices that this procedure appears to me seldom justifiable.

The operation that I wish to recommend appears to me the best in most cases in children, and in many cases of the so-called buried or submerged tonsil in adults. It was first recommended by me several years ago and has since been adopted by a considerable number of laryngologists, but I fear that the technic is not thoroughly understood by most laryngologists or general surgeons. The instruments required for the operation are a mouth gag, tongue depressor, blunt hook, tonsil forceps, long pincette and two snares with wire. One should also have proper sponges. In most cases one should also have at hand Lowenberg's forceps or some modification of the same for removing the pharyngeal tonsil, or such other instrument as one may prefer for this purpose. I have also for use, when Luschka's tonsil is to be removed, a nasal bone forcep that I pass through the nostril to the nasopharynx for removing pieces of Luschka's tonsil from the vault of the pharynx close to the choanæ, which may be difficult to catch with the instrument in the nasopharynx; and also for the purpose of opening the posterior nares, which will be found considerably contracted in a considerable number of cases. Any good mouth-gag may be used, but I prefer the Allingham, or some of its modifications. Any satisfactory tongue depressor may be employed. I formerly used, for separating the anterior pillar of the fauces from the tonsil, a blunt hook originally designed for a palate retractor, but I have recently had made for this purpose a much better instrument, with two blades, which when closed and locked form a blunt hook. (Fig. 1.) When the catch is loosened the blades may be opened out so that the two ends forming the blunt hook thoroughly separate the anterior pillar of the fauces from the tonsil by a single movement, thus considerably facilitating the operation. The tonsil forceps is an instrument that I had made for this special purpose. (Fig. 2.) It is about eight inches in length, with a catch on the handles so that it can be locked after the tonsil has been seized. The blades of this forceps turn at an angle of 45 degrees to the long axis. They are nearly an inch in breadth at their broadest part and are rounded down toward the end so that when the loop of wire has been slipped over their broadest part it must necessarily slide toward their end to the base of the gland. The end of the blade consists of two blunt points, each about an eighth of an inch in width, separated about three-eighths of an inch from each other by a crescentric depression, which leaves an elliptical opening about three-eighths of an inch long by one-fourth inch in width, when the points of the two blades are brought into contact. At Dr. O. T. Freer's suggestion these forceps are sometimes made with three points at the end of the blade. The instrument is so made that when the handles are locked the points of the blades press firmly against each other, and the handles have enough spring to allow for what we might call the root of the tonsil between the ends of the blades. The pincette is about eight inches in length; it is designed to hold the end of the uvula to prevent it from being caught in the loop of the snare. The snare for removing the tonsil is the same as used for nasal polypi, but I have the handle five inches in length so that it will not be necessary to shorten the wire before the tonsil is cut off. With the snare I use No. 5 steel piano wire. For removing the pharyngeal tonsil I like best John N. Mackenzie's modification of Loewenberg's forceps. The nasal forceps (Fig. 3) are the bone forceps that I have recommended for trimming up spicula of bone in operations on spurs of the septum. I give the patient a general anesthetic and prefer chloroform for children. The patient is placed in the prone position, with the face drawn out over the edge of the table, in which position there is no danger of blood flowing into the trachea. I prefer removing the right tonsil first, the patient being placed, when daylight is used, in front of a window; I seat myself, with my left hand toward the head of the table, on the opposite side of the table from the window, and reflect the light into the throat from a head reflector. After the first tonsil is removed the patient's face is turned toward the window, the face being kept downward during the turning so that no blood runs into the trachea, and the reflector is dispensed with. It is usually more convenient to use artificial light when we have an electric lamp that can be worn on the forehead, but even then I prefer to remove the right tonsil first, because this leaves the patient, when the left tonsil has been removed, in the position with my right hand toward the head of the table, in which I want him for removal of the pharyngeal tonsil.

TECHNIC OF THE OPERATION.

When anesthesia is nearly complete the patient is placed in the prone position, and the mouth-gag is placed between the jaws on the upper side of the face, and opened as widely as necessary. It is usually found necessary to continue the anesthetic for a few minutes afterward to complete the anesthesia, because these patients do not breathe well on account of the nasopharynx being filled with adenoid growth, and they do not come fully under the anesthetic until the gag is put in to hold the mouth open. For the right tonsil, sitting with my left hand toward the patient's head, I introduce the blunt hook between the anterior pillar of the fauces and the tonsil, while the tongue is kept down by the depressor held in the left hand. I then remove the tongue depressor and open the blades that terminate in the blunt hook widely enough to separate the anterior pillar thoroughly from the tonsil, by which act the tonsil is freed from a considerable part of its bed, so that it may be easily caught by the forceps. In cases where the anterior pillar is not attached to the tonsil this is not necessary, but the gland may be grasped at once with the tonsil forceps. In applying the tonsil forceps it is usually best to have an assistant press the tonsil inward with the fingers applied just back of the angle of the jaw, so as to make the gland as prominent as possible. In seizing the tonsil one should pass the blades of the forceps beyond the anterior pillar; otherwise it is apt to be slightly injured. When the tonsil has been seized the handles of the forceps are locked, the tip of the uvula is then secured with the pincette, which may be held by an assistant, and the loop of the wire of the snare is slipped over the handles and carried along them into the mouth and over the end of the forceps. If the tonsil is of fair size, so that it is held firmly, it may now be drawn on and lifted up so as to make certain that the wire slips under it; otherwise a little care will be necessary to make sure that the wire is beyond the broadest part of the blade, so that when it is tightened it will slide down to the end of the blade and slip under the gland, to cut it off at the lowest point. The wire loop is now drawn tightly about the base of the tonsil by a moving bar on the handle of the snare; the pincette is then removed and the milled wheel on the handle of the snare is brought into use for the final tightening of the loop. In nearly all cases, if care has been taken in grasping the tonsil, every portion of the gland will be removed at once, and if it has not been necessary to separate the anterior pillar the bleeding will not have exceeded a dram. The patient is then turned so that the face projects over the left edge of the table, the blood is wiped out of the mouth, the left tonsil is caught and extirpated in a similar way; then, if the pharyngeal tonsil is enlarged, it is also thoroughly removed. In the latter case the after-treatment consists of the application through the nares four or five times a day of an antiseptic oily spray or of a 1-4,000 solution of adrenalin chlorid or suprarenalin in a saturated solution of boric acid, and if the child is large enough an antiseptic gargle is used several times daily. When only the faucial tonsils are removed it is desirable to have the throat sprayed or gargled with some non-irritating antiseptic about once an hour for two or three days, and afterward about half as frequently until healing is complete. The child should be kept in the house for nearly a week, for the whole wound can not be expected to heal within less than ten or twelve days.

34 Washington Street.

DISCUSSION.

Dr. G. Hudson Makuen, Philadelphia—Some years ago I saw Dr. Ingals do this operation in his office and was so impressed with the thoroughness of it that I immediately secured the instruments. The first case on which I operated was a child of five years, and I removed the tonsil with great satisfaction, but three or four days later, to my surprise, I found that the child had no uvula. I was interested in hearing that Dr. Ingals has had similar experiences and I should like him to explain how and why these accidents occur.

Dr. William E. Casselberry, Chicago—In speaking of tonsillectomy before my classes, I divide it into tonsillectomy in children and tonsillectomy in adults. In children I divide again into operations with general anesthesia and those without it. Take first tonsillectomy in children with general anesthesia, I determine whether to use the snare or other instrument, observing whether the tonsil is of the pedunculated or of the submerged type. It is with the pedunculated type that I have found the snare particularly applicable. When they are loose and project well toward the median line, not being tied down to the triangular space, I find very little difficulty in enveloping them with the snare and making the enucleation of the tonsil. The method adopted in such cases on children under general anesthesia is by means of the curved vulsellum forceps, which occupies much less space than the one exhibited. I use No. 7 piano wire because it maintains its resiliency and cuts sufficiently well. The loop is applied to the tonsil and the vulsellum forceps takes it up, the tonsil is drawn into the loop of the snare; the same procedure is then repeated on the opposite side. This operation is usually done in conjunction with the removal of adenoids. In the second type of cases with general anesthesia we more frequently find the flat, adherent or submerged tonsil. I often find it difficult to break up these attachments and for this class of cases I believe the instrument exhibited would work admirably. All the easy cases seem to go to other men, leaving the more difficult cases for those of us who are specialists. They are usually divided into segments, one-half of which is adherent to the anterior pillar and the other to the posterior pillar. I find also that the lobe is higher developed and is covered with muscular tissue. I have not found it wise to use the snare to a great extent in these cases, but prefer to dissect them out. If there is any considerable part that the tonsillotome will take in bulk, I use that first and then supplement it with the forceps in order to make a thorough tonsillectomy.

Dr. J. A. Stucky, Lexington, Ky.—I do not think I have used the guillotine a dozen times in the last three years. I use the snare entirely. I find I can do a cleaner operation in the first place, and that it diminishes the danger of subsequent hemorrhage. There is one difficulty I hope Drs. Ingals and Casselberry will tell us how to overcome; I refer to the necessity for an assistant to hold the tongue down. I find I have trouble in removing the right tonsil, where I have to hold one hand over the other; I need an assistant to hold the tongue down and use the forceps. It is astonishing how dexterity develops in the use of the snare, and after using it a number of times with a heavy wire it will be found much superior to the guillotine or scissors.

Dr. George L. Richards, Fall River, Mass.—I like this method very well, but, except in children, I do my operations without anesthesia. I have done it a number of times by injecting the tonsil with local anesthetics, using the Schleich anesthesia tablet, the operation is practically painless. I use the vulsellum forceps, drawing the tonsil through the loops and maintaining traction as the snare is tightened. The form of tonsil snare with a groove in the side of the ring, in which groove the wire loop is formed, answers admirably. It is somewhat awkward to use, but allows one to exert much firmer pressure against the side of the throat without bending of the wire loop, and is sufficiently powerful for all tonsils. I have found the tonsillar wound to be much more painful and the healing much slower than after operations with the guillotine. This would seem of necessity to be the case, as a wound made with a sharp instrument like the knife will heal quicker and be less sore than one made with a No. 7 or No. 8 piano wire.

Dr. George B. Wood, Philadelphia—I have had some experience in removing tonsils with a snare, and I want to indorse what Dr. Richards says about the reaction following the operation. I have found it to be almost threefold as great as that following the use of the tonsillotome.

Dr. P. S. Donnellan, Philadelphia—As my experience with the treatment of enlarged tonsils becomes more extensive, I get more and more away from the use of the guillotine and use the snare or the forceps and scissors. I do not believe that any one operation can be used in every case. I believe the snare operation to be one of the very best.

Dr. S. H. Large, Cleveland—Two months ago I recorded 100 cases of operations on the nose and throat with ethyl chlorid anesthesia, but the guillotine was used. This method of anesthesia would not be sufficiently prolonged. We had no bad results and the patients experienced no unpleasant symptoms in taking it.

Dr. E. Pynchon, Chicago—In my experience the indications for this operation can be classified into, first, those appreciated by the patient, and secondly, those recognized by the physician. The call for operation may be recognized by observing the escape of secretions from the diseased tonsils, or by some condition of the gastrointestinal tract, due to the swallowing of such secretions. The size of the tonsil is no criterion for its removal. I understand Dr. Ingals to advocate the use of a general anesthetic. I think the dangers of anesthesia are sufficiently grave to contraindicate its use except in cases where it is absolutely necessary. If the patient is 13 years old, or older, I invariably use cocain. At this time we are much at sea as to the physiology of the tonsil. I have operated on as many as a thousand cases and never yet have had a patient afterward make any complaint due to the loss of the tonsil. As to the line where the separation from the anterior pillar should be made, I would call attention to the line of demarcation where the redness of the tonsil changes to the pinkness of the pillar; that is my line of separation. As to the method of procedure, I am guided by the age and tolerance of the patient. With small children I do a tonsillotomy. The tendency of the snare is to cut along the line of least resistance and, therefore, the dissection must be made sufficiently deep to leave only a pedicle remaining. The greatest disadvantage of the cutting operation in adults is the matter of hemorrhage, and for that reason a bloodless operation is better if it can be done. Dr. Ingals mentions the use of electricity; by the use of the cautery I am frequently able to do a bloodless operation. Dr. Ballinger of Chicago has been using the snare a great deal, and he says that one of the worst hemorrhages he ever had was following the use of the cold snare.

Dr. Otto J. Freer, Chicago—I have done this operation many times and think that it is an ideal method for the removal of the class of tonsils called buried or submerged. It takes these out so cleanly from the very bottom of the tonsillar niche that nothing could be more perfect. It removes projecting hypertrophied tonsils quite as well and in children, where adenoid vegetations are to be cut away simultaneously under an anesthetic, it is the method I prefer to all others, but where projecting tonsils alone need ablation the tonsillotome is preferable. I added the third tooth to the forceps because I found that the two-pronged one slipped off from the tonsil at times. The kind with the third tooth does not let go. I also cut off the uvula once, but since I have used Dr. Ingals' uvula forceps I have no fear of a repetition of the accident. The operation is a good one for submerged tonsils, because the tonsillar forceps is a strong instrument and may be crowded in above the velar lobe and under the bottom of the tonsil and thus be made to lift the tonsil completely from its bed. My greatest trouble used to be the application of the snare, because I seized the forceps with it instead of the tonsil. To overcome this I devised a snare guard which contains the wire while it is being carried over the forceps on to the tonsil. The wire used in this guard should be No. 6 piano wire, so that it may have stiffness enough to be crowded into the groove of the guard to keep it from slipping out. Many other operators have mentioned to me this same trouble of catching the forceps with the snare. I never have the tonsil pressed up, but prefer to crowd in beneath it with the tonsillar forceps. As to the anesthetic, I prefer ether to chloroform because I have had several cases where the latter anesthetic caused me much alarm. I have never had any trouble from ether and find that children often go to sleep more rapidly under ether than under chloroform. Tonsillectomy by cautery dissection is a bloodless operation so far as its immediate results are concerned, but I know from personal experience that secondary hemorrhages of an alarming nature quite often follow it.

Dr. Robert C. Myles, New York City.—Dr. Ingals has originated and explained the use of the snare, and when we shall have mastered all the details, this operation will be considered the best of all. He speaks of separating the anterior pillar from the tonsil. If the throat be examined carefully, it will be found that the tonsil does not touch the anterior pillar except at one spot; in the upper portion inferiorly it is not more than half an inch from the anterior pillar. If the tonsil can be cut from its surroundings, mucous membrane and investing sheath, there will be very little reaction. This is the most perfect operation, but it is limited in its application.

Dr. J. A. Stucky, Lexington, Ky.—What is Dr. Ingals' experience with the self-retaining tongue depressor?

Dr. E. Fletcher Ingals—I have one, but never use it. I did not speak of the benefits of a general anesthetic in the case of hemorrhage. I formerly thought a hemorrhage would never occur when the tonsils were removed with the snare, but I had one case in which it would have been very difficult to control had not the patient been under a general anesthetic which enabled me to grasp and tie the bleeding point. I think the uvula gets into the snare, especially in cases where the tonsils are large and in close apposition. I cut it off in my early cases before I adopted the plan of catching it with a pincette, but never have the accident occur now. One of the speakers suggested that there would be great difficulty in using the forceps in submerged tonsils, but it is in these very cases that it is of the utmost value. With the use of the hook, or tonsil dissector, the glands are dissected out with one motion, and they can then be easily grasped with the forceps. The anterior pillar should be caught with the hook at the upper part at the point where it is in apposition with the capsule. I very rarely use an assistant excepting to give the anesthetic. I used to have some one press up the tonsil just as I caught it with the forceps, but I seldom do this now, as in nearly all cases it is easy to catch it without. The use of heavier wire in order to avoid catching the forceps might possibly be some help. I have had the wire catch the forceps a good many times, but when the tonsil is large enough to be grasped firmly it can be lifted out so that the wire loop must necessarily slip under it. I am not sure about the reaction being greater by this method, but it has not seemed so to me.

Special Article.

IMMUNITY.

CHAPTER II.

INFECTIOUS ETIOLOGY.

The microbic cause of a disease must be in hand before any logical attempt can be made to prepare an immune serum for the disease. It is not in all cases necessary that the organism be cultivated artificially, however; the conditions in rinderpest may be cited in which the body fluids of a diseased animal, known to contain the infectious agent, are used for immunization, although the microbe itself can not as yet be cultivated or recognized.

Koch's Laws.

There are so many possibilities of error, and so many errors have actually been made in regard to infectious etiology, that certain requirements in the way of proof are now habitually demanded before an organism can be accepted as the cause of a disease. These requirements are most frequently expressed in the form of Koch's laws, which may be stated as follows: 1. The suspected organism must be found constantly in the proper tissues of an animal suffering from the disease, or which has died from it. 2. The organism must be cultivated artificially in a pure state. 3. It must be possible to reproduce the disease in a suitable animal by inoculation with the pure culture. 4. The organism must again be cultivated in a pure state from the tissues of the experiment animal.

Agglutination Test.

Since these laws were formulated another procedure has been developed which may give valuable evidence as to etiology. This pertains to the agglutination test, or as we speak of it in connection with typhoid fever, the Gruber-Widal reaction. This principle, that in the acquiring of immunity to a microbic infection the serum of an individual gains in agglutinating power for the micro-organism, has been found to hold true in many infections. Consequently, if one has in hand the specific micro-organism for a disease, he would expect the patient's serum to have a stronger agglutinating power for this micro-organism than for others which were accidentally present; and this power would also be greater than that possessed by the serum of one who had not had this particular disease. In spite of some possibilities of error this test has been of distinct value in enabling us to recognize the specific microbe of a disease, as was the case in the identification of the germ of epidemic dysentery (Shiga).

Obstacles to Koch's Laws.

All Koch's laws have not been complied with in certain cases, because of various difficulties which have been encountered. First, the pathogenic protozoa can not be cultivated on artificial media (we must except the success of Novy and McNeal with certain trypanosomas); second, certain bacteria which may be found constantly in a given disease (spirillum of recurrent fever) have not been cultivated artificially; third, there are a few diseases which are peculiar to man and accordingly can not be reproduced in experiment animals (leprosy, influenza, scarlet fever, measles, etc.); fourth, some infectious agents are pathogenic for experiment animals, but do not reproduce in them a clinical or anatomic condition identical with that found in the original animal (typhoid).

Furthermore, failure to comply with all the requirements enumerated does not in some cases disqualify the organism as the causal factor. If an organism is found constantly in characteristic sites in a given disease and not in other infections, and if at the same time other microbes are not present or are present only by accident, there could be little or no hesitation in accepting this organism as the cause of the disease, even if it were impossible to cultivate it or to transfer the disease to animals. The typhoid bacillus has been cultivated from characteristic foci (stools, blood, spleen, urine, rose spots) in such a large number of cases, and the bactericidal and agglutinating powers of the patient's serum against this organism are so distinctive, that compliance with the third law, though desirable, is not now essential. The conditions are similar in reference to cholera and the cholera vibrio.

The conditions are so unique in some diseases that, although all Koch's laws have not been literally met, certain equivalents *have been met*. To illustrate, we may consider an anopheles mosquito which has become infected with the plasmodium of malaria by biting a malarial patient, as a culture medium; and the transferring of the infection to another patient by the bite of this mosquito as the inoculation experiment which is desired.

Specific Infectious Diseases.

The term "specific infectious disease" has come to have a very special meaning. It is applied to a disease having characteristic clinical and anatomic phenomena, which can be caused only by one particular micro-organism. Among the diseases which come within the limits of this brief definition, the following may be enumerated (the micro-organism which is the cause of each disease being also given):

Diphtheria	*Bacillus diphtheriæ*
Tetanus	*Bacillus tetani*
Typhoid fever	*Bacillus typhosus*
Cholera	*Vibrio choleræ*
Anthrax	*Bacillus anthracis*
Tuberculosis	*Bacillus tuberculosis*
Leprosy	*Bacillus lepræ*
Plague	*Bacillus pestis*
Dysentery (bacillary)	*Bacillus dysenteriæ*
Influenza	*Bacillus influenzæ*
Glanders (farcy)	*Bacillus mallei*
Chancroid	*Bacillus chancri mollis* (Ducrey)
Recurrent fever	*Spirillum obermeieri*
Gonorrhea	*Micrococcus gonorrheæ*
Epidemic cerebrospinal meningitis	*Diplococcus intracellularis meningitidis* (of Weichselbaum)
Actinomycosis	*Actinomyces bovis et hominis*
Blastomycosis	*Blastomycetes* and *Oidia*
Malaria	*Plasmodium malariæ*
Tick or mountain fever	*Pyroplasma hominis* (Wilson and Chowning)

A large number of animal diseases have their specific microbes, as do certain other human diseases which hardly concern us as to the subject in hand.

Unknown Etiology.

In addition to the diseases mentioned, there are several which from analogy we must place in the same group. Scarlet fever, measles, German measles, chickenpox, smallpox, yellow fever, typhus fever, hydrophobia and syphilis, are undoubtedly due to micro-organisms. Mallory recently found in the skin of four scarlet fever patients a protozoön-like body which he believes to be the cause of the disease, although he admits that much desired proof has not been obtained.[1] The *Diplococcus scarlatinæ* of Class, which a few years ago acquired some notoriety, has not been able to stand as the cause of scarlet fever in the face of rigid investigation.

Parker, Beyer and Pothier have announced the discovery of a protozoön, *Myxococcidium stegomyiæ*, in the mosquitoes which infect man with yellow fever; but Carroll maintains that this organism has no relation to the production of the disease. The *Bacillus icteroides*, which Sanarelli found in a rather high percentage of cases, is now generally considered as a contaminating organism.

It is possible that smallpox and vaccinia will be eliminated from the diseases of unknown causation, owing to the evidence of protozoön etiology that Councilman and his colaborers have obtained; however, for the present, the question may be considered *sub judice*[2] in view of the fact that the forms described bear a close resemblance to certain well-known types of cell degeneration.

The following animal diseases, of unknown etiology, may also be mentioned in this connection: Foot and mouth disease, peripneumonia, bovine pest, sheep-pox (clavelee), chicken-typhus or chicken-pest and epithelioma contagiosum of fowls.

Obstacles to Discovery of Microbes.

The following appear to be the chief reasons for the failure to discover the organisms of these diseases: 1. Inability to cultivate the microbe. (The spirillum of Obermeyer, and the leptothrix are examples of known organisms which have not been cultivated.) 2. Mixed, or symbiotic infections. It is conceivable that in some case the combined action of two micro-organisms may be necessary to cause the disease. The non-toxic products of the two may synthesize to form a toxic substance. 3. Unstainability of the microbe. 4. Ultramicroscopic size. The organism of the peripneumonia of cattle was cultivated by Nocard and Roux by growing it in a closed collodion sac which was placed in the peritoneal cavity of suitable animals. It is so small that its form can not be made out, and growth is recognized only by the clouding of the culture medium, and the increased virulence of the latter for animals.

Filterability of Viruses.

Some valuable information has been obtained by observing whether these infectious agents are so small that they will pass through dense filters of porcelain or infusorial earth. It has been found that the viruses of foot and mouth disease, peripneumonia, rinderpest, sheep-pox, chicken-typhus, horse sickness, epithelioma contagiosum of fowls, and yellow fever are filterable. This is determined by injecting the filtered culture medium or serum into susceptible animals. The viruses of smallpox and vaccinia are said to be non-filterable. Success in filtering the hydrophobia virus has recently been claimed by Remlinger. Inasmuch as scarlet fever, measles, chicken-pox, typhus fever and syphilis* can not be produced in animals, the filterability of their viruses is not at present susceptible of demonstration.

Non-Specific Infectious Processes.

There is a marked tendency in many diseases, typhoid, cholera, malaria, etc., for characteristic organs or groups of organs to be involved in some particular manner. These are features which stamp them as specific diseases. On the other hand, there is a large number of micro-organisms which cause no well-defined clinical and anatomic disease, but depending on various accidents, cause an *inflammation now in one organ, now in another*. Suppuration is not a specific disease because the pyogenic power is common to a large number of microbes.

A diphtheritic or pseudo-diphtheritic process in the mouth and throat may be caused by the diphtheria bacillus, streptococcus, staphylococcus, oidium or yeasts; bronchitis may be caused by the influenza, tubercle, plague and typhoid bacilli, and by the infecting agents of the acute exanthemata, etc.; pulmonitis by the pneumococcus, streptococcus, tubercle, plague, Friedlander and influenza bacilli, oidium, actinomyces, etc.; meningitis by the tubercle and influenza bacilli, streptococcus, staphylococcus, pneumococcus, gonococcus, diplococcus of epidemic meningitis, the syphilis virus, etc.; arthritis by the streptococcus, staphylococcus, tubercle bacillus, gonococcus, the virus of rheumatic fever, etc.; endocarditis by the streptococcus, staphylococcus, gonococcus, pneumococcus, tubercle bacillus, etc.; and septicemia by a whole host of organisms aside from those mentioned as causing specific diseases.

---

[1] Jour. of Med. Research, No. 4, 1904.

[2] Jour. of Med. Research, No. 1, 1904.

*Recently syphilis has been inoculated successfully into anthropoid apes.

Within certain limits, however, there is often a degree of specificity in the processes produced by some of the organisms mentioned, which sometimes allows of clinical and anatomic differentiation. The infiltrating and rapidly extending invasion of the subcutaneous and connective tissues caused by the streptococcus can often be distinguished clinically from the slower, more circumscribed process of the staphylococcus. The conditions induced by the *Bacillus aerogenes capsulatus*, or bacillus of malignant edema, are in turn different from those of the streptococcus and staphylococcus. The membranous inflammation of diphtheria may in favorable cases be distinguished from that of the pyogenic organisms without bacteriologic aids. In this possibility, however, there lies no justification for neglect of the bacteriologic examination.

Mixed Infections.

The coexistence of two or more micro-organisms in a morbid condition is of very frequent occurrence, and some of the most interesting and important phenomena seen in infectious diseases are referable to mixed, secondary or superimposed infections. Two exogenous infections may attack an individual at the same time. Measles and scarlet fever and diphtheria and scarlet fever have been known to coexist. Pneumococcus pneumonia and typhoid fever, chancre and soft chancre, chancre with pus cocci, syphilis and gonorrhea, diphtheria with streptococci, tetanus with gangrene-producing organisms, are common observations. One organism may intensify the virulence of another. Diphtheria accompanied by streptococcus infection seems to be more virulent than diphtheria alone. It is also believed that the presence of aërobic organisms (those which demand oxygen for their development) in a wound infected with the tetanus bacillus or the bacillus of malignant edema (anaërobic organisms), may increase the virulence of these infections. Streptococci are probably important organisms in scarlet fever for they are present in unusual numbers in the throat lesions and are often found in fatal cases in all the organs, yet it is believed that they constitute only a mixed or secondary infection superimposed on that of the scarlatina virus. The conditions are somewhat similar in smallpox, the pustules of which invariably contain streptococci, staphylococci, or both. In both scarlatina and smallpox these secondary infections may be responsible for many fatalities.

Pneumococcus pneumonia occurring during the course of, or during convalescence from the eruptive fevers, diphtheria, typhoid fever, erysipelas, a streptococcus septicemia developing during typhoid (giving rise to an irregular temperature curve), streptococcus infection of tubercular cavities, and the development of acute tuberculosis following or during measles —these are important examples of secondary infections.

We should naturally expect that the presence of a severe secondary infection might embarrass attempts at serum therapy. Experience on this point is practically limited to diphtheria, and there is no lack of evidence to show that the disease when complicated by severe streptococcus infections often can not be controlled by antitoxin treatment.

Infectious Intoxications.

It may be emphasized that there are certain diseases where a wide dissemination of the bacteria is not necessary for the production of morbid phenomena; where, in fact, they may be entirely localized (diphtheria, tetanus), and the symptoms produced by virulent toxins which are readily dissolved in the body fluids and carried to important organs. More especially, those microbes are placed in this class which, in our artificial culture media (bouillon), produce their specific disease-producing toxins in a soluble form. The bacilli of diphtheria, tetanus, botulism and the pyocyaneus bacillus belong distinctively to this group.

Snake venom and arachnolysin (spider poison) are the best known examples of soluble animal toxins. As will appear later, the serums of all animals probably contain a variety of toxins injurious to one or more species of animals.

(*To be continued.*)

Good Advice to the Young Graduate.—We clip the following from the *Tulane Phagocyte*, which is published in the interests of the alumni and students of the medical department of Tulane University, New Orleans: "We trust that our recent graduates, who have gone to take their places in doing the work and carrying the burdens of the profession, will devote some thought to the subject of this brief article. The man who enters the medical profession to-day, safeguarded as it is by proper legislation, equipped with excellent schools, given in some degree its proper place as a factor in the community, does not always realize that these things have not come of their own accord, but have resulted from the earnest and continuous efforts of his elder colleagues and their predecessors. The newcomers who fall heirs to the present state of the medical profession, social, political and scientific, owe a duty to that profession—to keep at least undiminished its present possessions and to add as much as may be proper and possible in each and every direction. Graduate of 1904, join your county or parish, your state, and finally the national society as the first step in the performance of this duty. Without organization very little is ever accomplished. Remember, too, that in thus doing your duty to the profession you will place yourself in the most advantageous position for doing your duty to yourself and to your patients. You will learn much that is valuable by rubbing against your colaborers, at the same time that you contribute to their acquisitions of medical lore. Again, your close acquaintance with them will give opportunities for co-operation to mutual advantage and eliminate unnecessary friction. Propinquity, they say, is the best matchmaker; it might be added that it is essential to friend-making. Send in your application for membership in your local society and then go on up, through your state society, into the American Medical Association, without membership in which you ought to be unwilling to rest satisfied."

Wounds of the Cervical Portion of the Thoracic Duct.—P. Lecenè (*Revue de Chirurgie*) reports a case in which the thoracic duct was divided in its cervical portion in the course of an operation for the removal of enlarged lymphatic glands in the neck. He has collected twenty-one cases of like character from the literature and he reaches the conclusion that such wounds, without being frequent, are not of exceptional rarity. They fall into two classes, according as they are observed in the course of an operation, or as the symptoms make their appearance afterward. In the first instance, the characteristic sign is the escape into the wound of clear or milky liquid, at times ejected rhythmically. In the second instance, the characteristic signs are the escape of chyle, either through the drain in the wound of operation, which often must be reopened; marked thirst, wasting, general asthenia and at times also oliguria. Among the twenty-two cases studied, death was noted in but one, and this occurred in the preantiseptic period. In all of the others, recovery ensued more or less rapidly as a result of the therapeutic measures employed. The prognosis as to life is, accordingly, not grave, although serious accidents may result from the loss of considerable amounts of chyle. The treatment varies in accordance with the conditions present. If the wound is discovered in the course of an operation, the peripheral portion of the duct should be ligated; the application of a ligature to the central portion is unnecessary in the vast majority of cases, as the valve in the duct is sufficient to prevent the escape of fluid. Ligation of the peripheral portion is unattended with injurious results, as has been shown by clinical observations on man and experimental observations on animals. Suture of the duct has been successfully effected in but one instance. The operation is applicable only in rare instances, in which the wound in the duct is incomplete. If the wound in the duct is not discovered until some time after the operation, a tampon may be applied, and recovery usually ensues rapidly. Reopening of the wound and exposure of the duct and its compression or ligation are permissible procedures and may prove successful, but they are always difficult and usually unnecessary, as simpler means generally suffice.

NOTIFICATION IN PULMONARY TUBERCULOSIS.

In the January nmber of *McClure's* an article on the warfare against tuberculosis contains a severe arraignment of the medical profession. According to the author, physicians have not only, with a very few exceptions, played an insignificant part in the recent campaign to exterminate tuberculosis, but have actually hampered the work by their persistent opposition to the registration of cases and to the compulsory disinfection of infected dwellings. The author speaks of the "blind bitterness of prejudice" of the medical profession, "which is one of the most potent allies of the disease." The medical department of the University of Pennsylvania is credited with having defeated the compulsory registration law in that state, and in other states the opposition to such a law has always been headed by physicians. Chicago physicians are accused of sending such untrustworthy reports as to deaths from tuberculosis that the department of health is forced to depend on undertakers' certificates for its mortality statistics. The same opposition on the part of the profession is said to stand in the way of compulsory disinfection. As a single instance, Indiana is said to have a state law providing for compulsory disinfection, but "public sentiment led by medical sentiment" is against it.

Such criticism, absurdly unjust as it seems, should not be passed over lightly, for it may contain some slight element of truth. Of course, a popular writer can hardly be expected to realize that no progress would ever have been possible in the warfare against tuberculosis had the medical profession shown the indifference with which he charges it. On the contrary, all popular movement in this direction must necessarily follow the lines laid down by medical science.

The reason why laymen have taken so prominent a part in this movement is that tuberculosis is a disease depending largely on social conditions which can be corrected only by the efforts of the community at large. The profession has recognized this social element in tuberculosis for almost twenty years and, had the laity been prompt to follow the teachings of physicians, the disease would have been half conquered by now. The point in these charges which is worthy of serious attention is the alleged opposition to compulsory registration and disinfection on the part of the medical profession. It is perfectly true that there is a widespread feeling of opposition to registration, which must have some reasonable basis or it would not exist. The cause given by the author of the article is that physicians object to making official reports for which they are not paid. This objection may exist in the minds of some physicians, yet undoubtedly the majority are actuated by motives of a quite different order; they fear, and perhaps justly, that the compulsory reporting of cases will so attract public attention to the infectiousness of tuberculosis as to increase in the popular mind the already exaggerated fear of contact with tuberculous persons, and also that this measure will subject their patients to annoying interference and publicity.

As to the first objection, namely, that physicians decline to report because they are not paid for doing so, the most obvious counter-argument is that the state confers special privileges on physicians, for example, freedom from jury duty and preference in the payment of claims against an estate, and in return for these the state may reasonably demand such a service as the reporting of contagious diseases, even if it had not the supreme right to demand any service which the public health required.

The other two objections must be treated with far more respect. Phthisiophobia is a real danger. We are all aware of the fact that the chief progress the laity has so far made in the understanding of tuberculosis is to acquire an exaggerated idea of its infectious nature. Indeed, thus far the "tuberculosis crusade" seems to have doubled the hardship to a great number of consumptives by making them objects of fear and suspicion, while it has succeeded in alleviating the lot of only a small minority. If it were true that registration could not be carried on without increasing this undue dread of the consumptive, then the measure could not be justified, however useful it might prove in the gaining of important information. It is, however, perfectly possible to devise a practicable method which shall furnish the desired information without violating the physician's confidence. The practice has been tested and found to work successfully of furnishing to physicians postal cards on which the name and address of the patient is to be written and a statement made as to whether or not the physician desires to have an inspector sent from the board of health to visit and instruct the patient and his family. In case the inspector's visit is not required the matter ends there; the board of health has gained its information, and the patient is not even aware that a report has been made. It is true that complaints have sometimes been made that after a report has been sent in the patient is assailed by advertisements of proprietary remedies and so-called cures for consumption. If such complaints are in any degree justified by the facts, they do not at all impeach a proper system of registration, but only impeach the board or bureau, through the connivance of whose officials lists of tuberculous patients are obtainable.

The value to the public health of a system of registration of all tuberculous cases can hardly be denied by any one who has at all concerned himself with the modern warfare against this disease. The same may be said of the corollary of this measure, namely, compulsory disinfection of dwellings. The first essential in combating any infectious disease is definite knowledge of its extent and distribution, and how is this knowledge possible unless all cases of the disease are reported? The importance of house infection in the spread of tuberculosis is receiving more attention all the time, and it is difficult to see how any one familiar with the poorer part of our population, whether in country or city, can object to a measure which aims to remove this particular source of infection.

New York City, after several years of compulsory registration of tuberculosis, has succeeded in collecting a most valuable series of statistics which enable her to find the plague spots in that city, and to inaugurate rational sanitary reform. It is not by covering up the actual facts as to the extent of the disease, while encouraging a general agitation as to its infectiousness, that we may hope to rid the popular mind of phthisiophobia. General apprehension as to the dangers of tuberculosis has been enough aroused, it is now time to turn this feeling into constructive channels.

As a basis for sanitary reform of the poorer parts of a city, for compulsory disinfection of infected houses, for the proper location of dispensaries for the tuberculous poor and for the consequent erection of appropriate sanatoria for different classes of patients, a knowledge of the distribution of the disease, which can only be gained by a good system of registration, is essential.

ALBUMINURIA DUE TO PALPATION.

The prompt reaction of the kidneys to circulatory disturbances has long been known, and albuminuria of a transitory character dependent on such changes is not infrequently seen. It has also been shown experimentally that thoracic compression, general, or confined to the lower thorax, and general abdominal compression will cause transitory albuminuria. That direct manual compression of the kidneys may, under certain circumstances, cause albuminuria has not been so widely recognized.

Schreiber[1] has recently called attention to this form of albuminuria, which he characterizes as renal palpatory albuminuria. It was first described by Menge. in 1880, but its clinical possibilities do not seem to have been appreciated at that time. Schreiber restudied the phenomenon, and endeavored to find out how normal and movable kidneys reacted under palpation. Dividing movable kidneys into three grades, according to the classification suggested by Hilbert, he found that in the medium and severe grades palpation was always followed by albuminuria, and in the mild grades palpatory albuminuria was almost constant.

The degree of albuminuria varied in different cases, and did not necessarily correspond to the grade of dislocation, to the palpability of the kidney, nor to the duration of the palpation, as might have been expected *a priori*. In 41 cases in which albuminuria was present, there was only a trace in 14, while in the other 27 the amount varied from a slight flocculent precipitate to 3 per mille by Esbach's method. The duration of the albuminuria was usually very short, and in this it differed from the albuminuria of organic disease. Schreiber states that the urine should never be examined later than ten minutes after the palpation has been done, as in one of his cases the albumin had disappeared after twelve minutes. In some cases albumin was still present two hours after the palpation, but such cases were exceptional.

The urine generally showed physical and microscopic changes when albumin was present. After palpation it was often lighter in color than previously, and in some cases an excess of phosphates was present. The microscope always showed an increase in the epithelial cells, and frequently red blood cells and leucocytes were found. The leucocytes were generally partly polynuclears and partly mononuclears, but in one or two instances were almost entirely lymphocytes. In no instance were true casts found, though occasionally pseudo casts were present.

Schreiber discusses various possibilities regarding the origin of the albumin. It can not be due, he thinks, to actual injury to the kidney tissue, for it is too transient, nor can it be due to injury of the vessels with rhexis, because red blood cells are not constantly present. He inclines to the belief that a variety of factors are concerned, and he cites, as the most important, pressure of blood serum from the blood vessels, pressure of lymph from the lymph channels and changes in the blood pressure. The not infrequent presence of blood cells shows the likelihood of the first cause, the occasional exclusive presence of lymphocytes the second, and the fact that the albuminuria is at times out of all proportion to the intensity of palpation the third.

In the latter part of his article Schreiber discusses the effect on the kidney of indirect compression such as is exerted on the right kidney in palpating the liver. He also cites cases to show the value of the procedure in dystopia of the kidney and in doubtful abdominal tumors. So far as indirect palpation is concerned he comes to the conclusion that it very seldom produces albuminuria, and when it does the albumin is very slight in amount. His cases demonstrate that palpatory albuminuria may be of distinct value in differentiating obscure abdominal tumors. He suggests that in some cases the use of his method may obviate the necessity of more serious procedures, such as catheterization of the ureters, or exploratory laparotomy. Schreiber does not claim marvelous results from his method, but simply regards it as an aid to other methods which at times may be of value; as such it is worthy of extended trial.

EXPERIMENTAL STREPTOCOCCUS ARTHRITIS IN RELATION TO THE ETIOLOGY OF ACUTE ARTICULAR RHEUMATISM.

In England the view seems to be gaining ground that acute articular rheumatism is caused by a special micro-organism—*Micrococcus rheumaticus*—which has been isolated by various investigators from the blood, the urine and the joints of cases clinically regarded as acute articular rheumatism. Naturally, this view was materially strengthened when it was found that this coccus, which does not present any decisive cultural and morphologic differences from ordinary streptococci, produces arthritis and endocarditis when injected into rabbits. Most recently Beattie,[1] for example, after working with an organism obtained from the synovial membrane of a girl with acute rheumatism, came to the conclusion that *Micrococcus rheumaticus* is a distinct microbe, and the special cause of acute rheumatism.

There seems, however, to be good reason to go slowly in accepting this conclusion as final. There are, indeed, two very weighty objections in particular that must be removed before such acceptance can become possible. The first is that competent observers in various countries—Cole in Baltimore and Jochmann in Breslau, among others—have failed to find *Micrococcus rheumaticus* or any other microbe in the joints or in the blood of typical cases of acute articular rheumatism. The second objection is that Cole[2] has been able without any particular difficulty to produce in rabbits arthritis and endocarditis by means of intravenous injections of streptococci from diverse sources.

The results obtained by Cole were in every way quite similar to those obtained by the English observers on injection of the so-called *Micrococcus rheumaticus*, and regarded by them as sufficiently distinctive effects to justify them in regarding this microbe as a definite variety or species of streptococcus. Manifestly, the faculty of producing arthritis and endocarditis in rabbits by itself does not warrant the establishment of a distinct form of streptococcus. In view of these two objections we clearly are not warranted in regarding the etiology of acute rheumatic fever as solved in the sense of the English observers. Of course, it must be acknowledged that their work seems to emphasize the importance of streptococci in causing articular and endocardial lesions similar to those of acute rheumatism. Whether streptococci are the real cause of acute rheumatic fever—much might be cited that speaks for such a view—is, however, a question that can be solved only by continued investigation. The negative results obtained by Cole, Jochmann and others from their cultural experiments indicate at least that the complete solution of the problems connected with the etiology of acute rheumatism is not such an easy matter as it might appear at first sight.

TRUTH AND POETRY CONCERNING URIC ACID.

IV.

Horbaczewski, as we have pointed out, demonstrated the very important fact that uric acid may be derived from nucleins, but went off at a tangent and maintained that it does not come from all nucleins, but only from the nucleins of leucocytes. His arguments, it must be admitted, sounded plausible enough. He maintained that his studies showed, as a rule, a parallelism between leucocyte counts and uric-acid excretion. Where the parallelism failed he explained the discrepancy by assuming a class of leucocytoses without leucocytic destruction. The blood of children contains more leucocytes than that of adults and this, he believed, accounts for the relatively great excretion of uric acid in the former. Further, he brought the increased excretion of uric acid after eating, especially after a meat diet, into relation with the digestive leucocytosis. Feeding nucleins increased uric-acid excretion, but so convinced was he of his new view, that he assumed that the nucleins fed acted only indirectly by first producing a leucocytosis. Quinin diminishes leucocytosis, accordingly Horbaczewski thought it diminishes uric-acid excretion. Pilocarpin, he stated, increases both uric-acid excretion and the leucocyte count.

Medical men for a time rushed like a flock of sheep after Horbaczewski. Hypnotized, as it were, by the brilliant proof of the origin of the uric acid from nuclein, they were eminently susceptible to any suggestion that came from him. Thus Horbaczewski's theory of an origin of all uric acid from leucocytic nuclein alone, despite its flimsy foundation, met with remarkably general approval and acceptance. Many confirmatory reports of uric-acid determinations running parallel to leucocytoses were made; discordant findings were lightly explained away.

A new impetus to work on the urine was given in 1895 by Krüger and Wulff, who introduced a method for easily and quickly determining the amount of alloxuric bodies (uric acid plus xanthin bases) excreted. The idea gained ground that some of the discrepancies in the results above referred to might depend on the fact that in the decomposition of leucocytic nucleins both xanthin bases and uric acid are formed and that the relative amounts of these vary under different conditions of metabolism; if the total alloxuric bodies could be easily determined a parallelism of their excretion with the leucocyte count might, it was hoped, prove to be more constant than that of the uric acid alone. Leukemia was the disease which invited a special investigation in this regard, and between 1894 and 1898 we find a number of researches bearing on this subject. The results were, however, very conflicting, and in 1897 Hüppert and, in the same year, independently, Salkowski proved the total unreliability of the method of Krüger and Wulff; no importance, therefore, is to be attached to results based on its application to the study of our subject unless they are also supported by more accurate analytical methods.

[1] Brit. Med. Jour., Dec. 3, 1904.
[2] Jour. of Infec. Dis., 1904, vol. i, p. 714.

Even when more exact methods were employed, very contradictory results were obtained by equally good observers. In the study of pneumonia, especially, there was no concordance. While some maintained that the uric-acid excretion is increased at the height of the leucocytosis, others asserted that it is only after beginning absorption of the exudate that uric acid is excreted in larger amounts. The studies by Kühnau[1] were among the most elaborate. He corroborated Horbaczewski's view as a result of his examination of the metabolism in pneumonia and pleurisy and where a leucocytosis appeared with no corresponding increase in uric-acid excretion he even thought it probable that the leucocytes wander gradually back into the tissues without undergoing destruction.

A modification of Horbaczewski's view was suggested by Dunin and Nowaczek.[2] These investigators denied that the increased uric-acid excretion in pneumonia keeps pace with the increase of leucocytes in the blood, but attributed it solely to the absorption of the resolving exudate, and Carlyle Pope's findings in 1899 may be similarly interpreted.

Richter,[3] in 1895, had published a long series of observations which indicated that no constant relation between leucocytosis and uric-acid excretion can exist; in spite of his results he still leaned more or less on Horbaczewski's view.

Enough has been said, perhaps, to show what a sorry state the subject was in at this time. Some workers felt sure that the presence of a leucocytosis in the peripheral blood indicates an increased destruction of leucocytes; others were equally sure that a hypoleucocytosis is a certain indication that leucocytes are being destroyed, both sides apparently forgetting two important facts (1) that the number of leucocytes existent at any time represents the algebraic sum of the leucocytes manufactured and the leucocytes destroyed, and (2) that the number of leucocytes present in a peripheral vessel often depends on abnormal distribution rather than on abnormal production or destruction.

The factor of distribution of leucocytes in relation to leucocytosis was emphasized by Rieder in 1892 and later by Goldscheider and Jakob in 1894. John Billings, Jr., at the Johns Hopkins Hospital proved how the cold baths given to typhoid patients temporarily lead to accumulations of leucocytes in the cutaneous blood vessels, and Bohland,[4] in 1899, showed that atropin causes hypoleucocytosis in peripheral vessels, while the capillaries of the lungs are dilated and crowded with leucocytes; pilocarpin causes diminution of the leucocytes in the lung capillaries. Pilocarpin, it is said, increases uric-acid excretion, while atropin does not. His explanation was that pilocarpin increases the decomposition of nuclein, in spite of the absence of leucocytosis, and so more uric acid is excreted.

The sum of all these researches shows that while destruction of leucocytes in the body leads to increased uric-acid excretion, the number of leucocytes in the peripheral vessels is no gauge for the amount of leucocyte destruction going on nor for the amount of uric-acid formation. Moreover, a whole series of conditions has been studied in which there is increased uric-acid excretion without leucocytosis or evidence of leucocytic destruction. In many of these conditions nucleated cells other than leucocytes are destroyed. Again, as Minkowski[5] states, there is good reason to believe that an increased function of nucleated cells, without actual cell destruction, may be sufficient to augment nuclein cleavage and uric-acid formation. Indeed, it is not impossible, as Melis-Schirru[6] suggests, that increased uric-acid excretion and leucocytosis may be due to one and the same cause. If the activity of the hemopoietic organs be increased from any cause, the first expression may be an augmented nuclein metabolism; if the activity be still further exaggerated, leucocytosis results.

Strangely enough, as far back as 1892, Mares[7] had recognized the fallacies of Horbaczewski's arguments and made their insufficiency clear. At that time he accepted an origin from nuclein, but urged (1) that uric acid may be formed by a vital chemical process through gradual metabolic decompositions of nuclein instead of by the passive process of cell-death and nuclear destruction and (2) that the nuclein of any of the body-cells, and not simply that of the leucocytes, may give rise to uric acid. Horbaczewski's star was, however, so in the ascendant at that time that but little attention was paid to these keen observations of Mares. And even Mares did not see the whole truth, for he denied the direct transformation of the nucleins of the food into uric acid; as to the possibility of the latter process we shall have something to say in a succeeding issue.

DAWN?

The "divine healing" business seems to be going awry. So long as there is "money in the business," divine healing is a fine thing to dole out to the other fellow. Of late there have been unmistakable signs that when the "healer," the "Elijah," the "apostle," gets ill the faith business appears depressed. Dowie and his family are seeking health in the Bahamas, where probably they are plucking "leaves of healing" from the tropic vegetation. At least, as a coincidence, apparently as a not unnatural sequence, we see in the newspapers of late no stories of remarkable "cures" performed by "the prophet." There are not lacking signs that a portion of the public is getting its eyes opened.

AN ENCOURAGING SIGN.

A comforting sign of the time in Chicago is the very general and respectful attention given by the public to the excellent hygienic suggestions offered weekly by the *Bulletin of the Health Department* of Chicago, and willingly reprinted by the newspapers. Seldom has it been the case that advice of this sort has been so respectfully received by American communities. The fact is a most encouraging omen to those medical men to whom it seems, at times, as if the public cared naught for their hard work for the good of the community. Other reward is largely denied the sanitarian. At least, it is for him a comfort to know that a community has learned to listen attentively and to give heed, to a certain extent at least, to advice and suggestions offered by medical men.

TEA DRINKING.

Every little while there is an outcry against the practices of tea and coffee drinking. Lately it has been alleged that the degeneracy observed in the lower classes of Great Britain is largely due to the immense quantities of tea which is drunk in that kingdom. Without any doubt, a few people do drink too much tea and would be better without it. But tea drinking, as in China, may be the salvation of a people from much greater evils. The decoction has at least the advantage of having been sterilized by heat, and water drinking in China has its dangers, as many an old traveler can testify. The immense quantities of tea used without apparent damage by some of the most robust peoples in the world other than the Chinese, such, for example, as the Russians, the Hudson Bay voyageurs and the lumbermen of the North, does not testify to its evil effects on general health, under proper conditions. For a cold country it is almost an ideal stimulant, reviving the energies, even after almost apparently complete exhaustion, and affording a feeling of comfort that hardly anything else can give, and this without any noticeable uncomfortable after-effects. Of course, in our civilization there are some who take too much of many things for their own good, but even in these cases it is hard to say that the evil is as great as sometimes charged. The practice of giving large quantities of strong tea to mere infants, which is common among certain of the poorer classes of our cities, of course can not be too much condemned, but it is astonishing how many infants seem to thrive on it. There should be some discrimination in the general condemnation of such stimulants as tea and coffee. They probably do more good than harm, and we should welcome their use if by any means or to any extent they can be made a substitute for things that are worse, and if the habit were universal in some of our insanitary communities we might find it here, as among the earthly Celestials, the safeguard against many serious evils. If the question is asked, "What is the poor man to drink?" there need be no hesitation in answering: "Tea."

NATIONAL DIET AND ITS CHANGES.

The diet of a country is popularly supposed to be an important element in making and fixing the character of its population, and yet it may be that we overestimate its importance in this regard. According to census statistics, there has been a large decrease in meat consumption and a corresponding increase in that of cereals and vegetables. Thus in 1850 the consumption of wheat was 4.30 bushels to each American. In 1900 it was 6.23 bushels. The Scotch diet of oatmeal has been adopted by the Americans within the last fifty years to a very great extent, as shown by the increase of from 0.90 bushels in 1850 to 3.86 bushels per capita consumption in 1890. There has been a corresponding increase in the item of vegetables, though the use of potatoes seems somewhat to have decreased. The use of sugar has nearly tripled per capita in the last fifty years, showing the importance of this carbohydrate in our diet. All this does not mean that we are becoming a nation of vegetarians, for we are still large meat-eaters and probably will continue to be such. It means, however, that the country is growing older, and is assimilating itself more and more in the matter of diet with other older countries. How far this will affect the national character no one can absolutely foresee, but that it will seriously modify it may be doubted.

THE PERIODICITY OF DREAMS.

Dreams are experiences shared by all mankind and their pathologic importance in some cases has always been recognized. They seem, however, to follow no laws. At least this has been the generally accepted opinion. Recently, however, an Austrian investigator, Dr. Herman Swoboda, has claimed that dreams follow a certain periodicity, that certain impressions or events are revived in the visions of the night at regular intervals; in men usually every twenty-three and in women every twenty-eight days. He has been able to predict certain specified dreams, he claims, according to this law, and gives instances which, he thinks, substantiate his position. He also utilizes this periodicity to explain certain peculiar phenomena, such as premonitions of facts occurring at multiples of the stated periods. The suggestion is an interesting one, but it appears to us that it will require a very much more extensive series of observations before it can be accepted as a law. There are comparatively few of us that can recall our dreams unless they are especially impressive, and even such dreams are apt to be forgotten quickly. That they are connected with certain bodily conditions is generally agreed, and when these are of a cyclic or periodic character it would not be remarkable if they were accompanied with certain modifications of the subconscious intellection of the slumbering state. Even here, however, we have certain difficulties in the study. A German medical man of some prominence in science once reported that he and another colleague made a special study as to the periodicity of certain classes of dreams, but came to the conclusion that there was no general law controlling their appearance. It would be unorthodox to assert that premonitory dreams have not occurred in the past, but it would be exceedingly uncomfortable if we had to admit their frequent occurrence in the present. While the line of study opened up by Swoboda is a captivating one, we still prefer to keep our expectations moderate as to its results.

ORGANIZATION OF HEALTH BOARDS.

As a direct result of the growth of our knowledge of the nature and cause of preventable diseases, infectious and otherwise, the work of our boards of health and public health officers is assuming constantly increasing scope and importance. Practically every state, every city, every village and every township in the United States has adopted various regulations and has established certain procedures looking to the preservation of health and prevention of disease, and has placed the carrying out of these measures in the hands of officials such as the members of the boards of health and the health officers. In most states, however, these various officials are working more or less by themselves, with comparatively little opportunity for helpful discussion of common problems with fellow-officials. It would seem that the time is ripe for discussion of the desirability of drawing together into voluntary associations for mutual and public benefit all the health officers in a state. The work which is being done by the Association of Massachusetts Boards of Health shows that much good may be accomplished in this way. The journal of this Association can not but be a direct stimulus to the Massachusetts health official. There are so many details in connection with public-health work in regard to which the public must be educated that, on this account, concerted action is required by those best acquainted with the situation. if satisfactory progress is to be made. For example, in many places the legal status of the health officer is far from satisfactory, and in view of the importance of his work the pay is generally inadequate. Lawmakers must be educated to understand that in matters of public health the best available expert service is none too good, and that expert service means expert pay. Again, concerted action of officials directly interested is needed to secure as promptly as possible adequate state and municipal bacteriologic and pathologic laboratories. In this important respect the first step is still to be taken in many states and cities. Naturally, associations of this kind would aid in securing intelligent, harmonious, well-organized administration of well-considered regulations in regard to matters of public health. For these, and for other reasons, state associations of boards of health would seem to be an important step in the development of public health in this country.

Medical News.

DISTRICT OF COLUMBIA.

Personal.—Dr. Carl H. A. Kleinschmidt, ex-president of the Medical Association of the District of Columbia, who has been seriously ill for some time, is now reported to be out of danger.

Incorporation Bill Referred.—The bill to incorporate the American Medical Association has been referred to the subcommittee of the judiciary committee, composed of Hon. Richard Wayne Parker, New Jersey; Hon. H. W. Palmer, Pennsylvania, and Hon. D. A. Armond, Mississippi, for consideration and report.

Health Report.—The report of the health officers for the week ended January 21 shows the total number of deaths to have been 138, of which number 80 were white and 58 colored. There were 90 births and 17 stillbirths. At the close of the week there were under treatment 22 cases of diphtheria, 34 of scarlet fever, 72 of typhoid fever and 2 of smallpox.

ILLINOIS.

Change in Wards.—The old contagious disease ward in Cook County Hospital is to be transformed into a medical ward with a capacity of 100 beds. The necessary alterations will cost about $4,000.

Personal.—Dr. Charles F. Smith, Kankakee, was painfully injured by being thrown from his sleigh in a runaway, January 17.——Dr. Charles M. Bumstead, Monticello, underwent an operation for fistula, at St. Mary's Hospital, Decatur, January 20.

Suit Dropped.—In the suit of J. L. Owens against Dr. Henry J. De Haan, East St. Louis, in which $10,000 damages was claimed for alleged malpractice in the treatment of a fracture of the thumb, the plaintiff's attorneys took a non-suit, after witnesses for the defense had testified.

Itinerant in Trouble.—"Dr." Bixler, a traveling "tape-worm doctor," is under charges, at Kankakee, of practicing medicine without a license. It is alleged that he gave medicine to "induce" a cancer of the stomach to pass through the bowels. The cancer was not complaisant and the patient died.

State Board Re-election.—At the annual meeting of the State Board of Health, held in Springfield, January 31, the following officers were re-elected: Dr. George W. Webster, Chicago, president; Dr. James A. Egan, Springfield, secretary. and Dr. Peter H. Wessel, Moline, treasurer. Plans for the board's crusade against tuberculosis were mapped out, and a bill recently introduced in the legislature providing for the establishment of a state hospital for consumptives was approved.

Chicago.

New Hospital.—A building site, 100 by 280 feet, at 1222-1224 North Clark Street, has been purchased by Dr. Emil G. Beck, on which he purposes to erect a hospital to cost $80,000.

Physician Held Up.—Dr. Erasmus M. Hill, a physician of the health department, while coming from the disinfection of a house which he had superintended, on account of smallpox, was held up by two men, January 27, and robbed of his money, revolver and pocket case.

The Week's Mortality.—During the week ended January 28, 558 deaths were reported, equivalent to an annual death rate of 14.61 per 1,000. During the previous week there were 591 deaths, and in the corresponding week of 1904, 549 deaths. The principal death causes were as follows: Pneumonia, 96; consumption, 60; Bright's disease, 44; violence, 39; heart diseases, 36; and nervous diseases, 30.

Increase in Pneumonia Mortality.—During November, the first month of the current pneumonia season, there were 260 deaths reported to the department of health, from this cause—a daily average of 8.6. In December there were 451 reported—a daily average of 14.5 and an increase of 40 per cent. During the 28 days of January there were 459 pneumonia deaths—a daily average of 16.4 and an increase of 11.5 per cent. over the December rate.

INDIANA.

A Four Per Cent. Verdict.—In the damage suit for $5,000 brought by Charles E. Gallimore against Dr. Oliver James Cory for alleged malpractice, the jury awarded the plaintiff $198 damages.

Asylum Physician Exonerated.—Dr. John F. Glover, assistant physician at the Southern Indiana Hospital for the Insane, Evansville, was exonerated on the charges of cruelty to inmates of the institution, after an investigation made by the governor and the State Board of Charities.

Has Mental Disease.—Dr. Monroe W. Webster, South Whitley, township trustee, has asked that a guardian be appointed, as he realizes that he is at times unaccountable for and unconscious of his actions. The disability is due to business and financial worries. He has been sent to a sanitarium for treatment.

Teachers' Society Organized.—About seventy of the instructors in the various deparments of the Medical College of Indiana have organized the Teachers' Society of the Medical College of Indiana, with the following officers: Dr. Frank B. Wynn, president; Dr. Norman E. Jobes, vice-president, and Dr. William T. S. Dodds, secretary-treasurer.

Property Goes to Hospital.—Mrs. Harriet Jones, New Albany, who died January 16 at St. Edward's Hospital, has provided in her will that after all just debts are paid, her home property shall be given to the institution.——In default of heirs, the property of the late Rev. John A. Mack has been awarded to St. Joseph's Hospital, Logansport.

Osteopath Fined.—Edward C. Crow, Elkhart, was convicted in the Circuit Court, January 4, of practicing medicine without a license, and was fined $25 and costs, amounting in all to $61.25. The court instructed the jury that it was unlawful for any person in Indiana to practice what is known as osteopathy without having first secured a license to practice medicine, of a limited license, or a license to practice osteopathy.

December Morbidity and Mortality.—Bronchitis, tonsillitis, influenza and pneumonia were the prevailing diseases in December. The exact order of prevalence was: Bronchitis, tonsillitis, rheumatism, influenza, pneumonia, scarlet fever, pleuritis, smallpox, typhoid fever, intermittent fever, diphtheria, erysipelas, diarrhea, inflammation of bowels, whooping cough, puerperal fever, typho-malarial fever, dysentery, cholera morbus, cerebrospinal meningitis and cholera infantum. Smallpox was less prevalent than in the same month last year. There were reported 472 cases in 38 counties, with 8 deaths. In the same month last year 523 cases in 50 counties, with 2 deaths. There was, therefore, a decrease of 9.7 per cent. in cases, of 5 per cent. in area invaded, and an increase of 300 per cent. in deaths. Not until deaths appear in a local smallpox epidemic can physicians induce the people to be vaccinated. Vanderburg County had 122 cases of smallpox; Dubois, 53 cases, 3 deaths; Clay, 12 cases, 1 death; Vigo, 53 cases, 4 deaths; Clinton, 12 cases; Floyd, 41 cases, and Boone, 12. The total number of deaths in the month was 8,856, equivalent to an annual rate of 12.6. In the same month last year 2,854, rate 12.6. The principal causes of death were: Consumption, 368; pneumonia, 351; violence, 163; cancer, 121; typhoid fever, 67; diphtheria, 33; scarlet fever, 22; diarrheal diseases, 28, and cerebrospinal meningitis, 30.

Personal.—Dr. Lewis L. Williams, Brazil, has been reappointed secretary of the Clay County Board of Health.——Dr. David L. Kahn and family, Indianapolis, have returned after a year in Europe.——Dr. John B. Fattic, Anderson, local surgeon for the Big Four System, has resigned.——Dr. Solomon D. Kell has been re-elected for the fourth time, secretary of the Liberty Board of Health.——Dr. James W. Milligan, South Bend, has been appointed physician and surgeon to the state repenitentiary at Michigan City, vice Dr. H. Lee Streaker, resigned on account of ill health.——Dr. Nicholas A. Kremer, Madison, has been made secretary of the *Jefferson County* Board of Health.——Dr. Harry H. Weist, Richmond, was painfully injured in a collision between his buggy and an electric car, January 2.——Dr. P. Livy Schuyler, Evansville, was painfully injured in a collision between his bicycle and a cab, December 29.——Dr. Charles F. C. Hancock, Jeffersonville, has been elected state senator.——Dr. John Halton and family, Muncie, have moved to Sarasoto, Fla., where he will have charge of a new hospital.——Dr. Charles M. Brown, New Marion, treasurer-elect of Ripley County, has filed a bond of $400.000.—Dr. Anthony E. Otto, Alexandria, fell on the ice at Orestes and broke his leg, January 16, while making a professional call.——On the occasion of the eighty-ninth birthday anniversary of Dr. W. H. Wishard, January 17, about 100 members of the Indianapolis Medical Society called on him and presented him with a testimonial engrossed on parchment.

IOWA.

Shelby County Medical Society held its annual meeting in Harlan, December 6. Dr. Mary C. Heilesen, Elkhorn, was elected president; Dr. Edwin B. Moore, Harlan, vice-president, and Dr. Frank H. Allen, Shelby, secretary-treasurer.

Marion County Medical Society held its annual meeting at Knoxville, December 8. Dr. Gaylord Worstell, Knoxville, was elected president; Dr. James L. Miller, Pleasantville, vice-president; Dr. Corwin W. Cornell, Knoxville, secretary, and Dr. John V. Brann, Knoxville, treasurer.

Hospital Control Transferred.—The Woman's Christian Association Hospital, Council Bluffs, has surrendered its control and management to the medical men of the city, who were represented by a committee consisting of Drs. Donald Macrae, Jr., Mathew A. Tinley and F. W. Dean.

Staff of Children's Home.—The following were elected as the medical staff of the Iowa Children's Home, Des Moines, at a meeting held January 16: Dr. James W. Cokenower, president and surgeon; Dr. James W. Osborn, secretary; Dr. William W. Pearson, ophthalmologist; Dr. Clifton Scott, neurologist, and Drs. Bernard J. Callahan, Wilbur S. Conkling, Roderic F. Watts, Francis A. Ely and C. A. Ayres, attending physicians.

New Hospital at Creston.—A new hospital, thoroughly outfitted, to be known as Mercy Hospital, is to be established in Creston, in the building formerly occupied by the Tait Sanitarium. The officers of the hospital association are: Hon. D. W. Higbee, president and counsel; Dr. Harry E. W. Barnes, vice-president; Dr. T. Elliot Tait, treasurer; Dr. John W. Reynolds, secretary, and Dr. J. W. Coakley, superintendent. The institution can accommodate forty patients.

KANSAS.

Personal.—Dr. Chilton W. McLaughlin, Kansas City, has returned after a trip to Europe.

Unlicensed Practitioner in Jail.—G. W. Knox has been convicted in Labette County of practicing medicine without a license and has been fined $50 and costs. On his refusal to pay the fine he was remanded to jail.

Communicable Diseases.—For the month of December there were reported to the State Board of Health 271 cases of diphtheria in 28 counties, with 35 deaths; 222 cases of scarlet fever in 32 counties, with 15 deaths; 426 cases of smallpox in 29 counties, with 1 death, and 120 cases of typhoid fever in 27 counties, with 31 deaths.

Acquitted.—In the case of Drs. Christopher C. Kesner and Gilbert G. Kesner, Leroy, charged with criminal carelessness in administering chloroform to and in performing an operation on Mrs. M. Short, the county attorney dismissed the suit, January 13.——Dr. E. P. Chase, Shawnee, charged with killing John Cahill, Aug. 22, 1904, was found not guilty, January 15.

New Hospitals.—The Salina Hospital and Training School for Nurses has been incorporated by Dr. William H. Winterbotham, Nathan D. Tobey, W. Scott Harvey, James R. Crawford, Manuel J. Brown, J. Harvey Winterbotham, Howard N. Moses, Andrew G. Anderson, Francis G. Lagerstrom, Edwin R. Tuttle, George Seitz and O. R. Britain. The staff is made up of the stockholders, but all licensed and ethical practitioners may send their cases to the hospital and attend them.——The new Arkansas City Hospital was opened for patients January 2.

KENTUCKY.

Senior Student Dies.—Hugh Adams, Madisonville, a senior student at the University of Nashville Medical Department, died January 16 at his home from tuberculosis, after an illness of a year.

Exonerated for Shooting.—Dr. Walter B. Gossett, Louisville, accused of unjustifiable assault on Dr. Henry B. Green and with shooting him twice, Nov. 7, 1904, was acquitted by a jury in the Circuit Court, January 19.

Smallpox Warning.—The State Board of Health estimates that in seven years there have been 25.000 cases of smallpox in the state, with 300 deaths, with a direct and indirect money loss to the commonwealth of $2,000,000, all of which might have been avoided and lives saved had vaccination systematically been practiced.

Personal.—Dr. Clyde Brady, Greenup, has been appointed an interne at the City Hospital, Louisville, succeeding Dr. William Fullbright, resigned.——Dr. William D. Powell, Harrodsburg, suffered a fracture of the clavicle and fractures of three ribs in an accident January 13, in which he was thrown from his buggy to the frozen ground.——Dr. Harry A. Davidson, Louisville, has been elected professor of physiology, embryology and chief of the gynecologic clinic in the Hospital College of Medicine.——Dr. Frederick G. Larue, Smithland, physician of Livingston County, fell and fractured his scapula and arm, January 11.

Railroads Will Clean Cars.—The controversy between the State Board of Health and the railroads of the state, in which it was claimed that the passenger cars were so superficially cleaned that they were common carriers of disease, has ended in the acceptance by the railroads of the following rules regulating the cleaning and care of cars used in the state, which have been drawn up by the board, and which will at once go into effect:

> All day coaches engaged in regular traffic shall be thoroughly cleansed after each trip at such points as facilities for the same have been provided. In no case shall such cleansing be less frequently performed than on every third day of use. In such cleansing, all rugs, mattings and upholstered seats and back rests, when practicable, shall be removed from the coach to the open air for mechanical cleansing, and be exposed to sunlight when the prevailing meteorological conditions will permit.
>
> All interior surfaces in coaches are to be mopped, scrubbed or cleansed at intervals of not more than ten days, with solutions of mercury bichlorid, carbolic acid, tricreosol or other disinfecting preparations preferred by any corporation, and approved by this board as to ingredients and strength.
>
> Spittoons are to be provided in numbers of not less than one for each seat in all smoking cars and toilet rooms, and one at each end of all other day coaches, and in all waiting rooms. Placards provided by this board shall be displayed at each end of all such coaches and in all waiting rooms, indicating the importance of using the spittoons, and it shall be unlawful for any person to spit on the floor or platform of any railway car, or other public conveyance or on the floor of any waiting room or platform in any station or depot.
>
> All coaches of any kind in which an acute infectious disease has been carried shall remain closed and unoccupied after such person has been removed until it has been thoroughly cleansed and disinfected by the use of formaldehyde gas in quantities of not less than forty fluid ounces of formalin to each coach. All day coaches in regular use for through travel are to be disinfected after cleansing by some method approved by this board at intervals of not more than ten days.
>
> All toilet rooms, water closets, urinals, spittoons and toilet appliances are to be scrubbed with soap and hot water and disinfected with formalin, or other approved method, after each trip's use, and shall be kept as clean as possible when on the road, and all similar rooms and in stations shall be cleansed daily in the same way, and when vaults or surface receptacles are used in stations these shall be disinfected daily with fresh lime.
>
> All preceding regulations in regard to cleanliness and disinfection shall apply equally to sleeping, dining, buffet and parlor cars used in the service of the public.
>
> All blankets, curtains and hangings used in sleeping cars shall be exposed to superheated steam, or other means of disinfection approved by this board at intervals of not more than ten days, and all mattresses shall be so treated at intervals of not more than sixty days.

MAINE.

Two-Thirds Insured.—In the fire at Brunswick, January 18, Dr. Goldbridge G. A. Stetson suffered loss amounting to $750, of which $500 was covered by insurance.

Bequest to Hospitals.—Macy S. Cope, Brookline, Mass., left by will $10,000 to Maine hospitals for free beds for patients from Washington County and specially from East Machias, his native town.

Epidemic Spinal Meningitis.—A camp of thirty lumbermen at Dover has been attacked by spinal meningitis. Five cases have occurred and three patients have died. The State Board of Health has assigned Dr. Galen M. Woodcock, Bangor, to investigate.

Eastman Sentenced.—Dr. Charles A. Eastman, Old Orchard, found guilty last July of manslaughter by an unlawful operation, withdrew his exceptions and was sentenced to be imprisoned one year at labor in the Alfred jail, the sentence to begin January 3.

MARYLAND.

Will Increase Medical Staff.—The medical staff of the Peninsula General Hospital, Salisbury, will be increased to include all the members of the local medical associations in Wicomico, Somerset and Worcester counties.

Personal.—Dr. Daniel P. Fahrney had a stroke of paralysis at Hagerstown, January 25.——Dr. Charles A. Wells, Hyattsville, who has been in active practice for the past 42 years, has retired to enjoy the fruits of his professional labors. Since retiring he has been elected president of the First National Bank of Lander, president of the Maryland Title Insurance and Investment Company, and president of the Maryland House of Correction.

Sheppard and Enoch Pratt Hospital Report.—The thirteenth annual report shows that 114 were admitted, 113 discharged and 105 remained under treatment at the end of the year. By the great fire last February thirteen pieces of the hospital's property were destroyed, and although the trustees had safeguarded their income by rental insurance, there will be a temporary impairment of income. Dr. Stewart Paton, who had been director of the hospital laboratory since 1899, went abroad in June and has since resigned, and Dr. Clarence B. Farrar has been made assistant physician and director of the laboratory. Dr. James H. Randolph of Florida was appointed clinical assistant, Dr. Chinn resigning to engage in private practice. Early in the summer the trustees authorized Dr. Brush to plan and equip apartments for hydrotherapy. Rooms, accordingly, were selected in the basement of one of the wings and the apartments will soon be ready for use.

Baltimore.

Osler Memorial Number.—The *Maryland Medical Journal* is preparing to publish an "Osler Memorial Number," June 1.

Personal.—William F. Frick, the founder and benefactor of the Frick Medical Library of the Medical and Chirurgical Faculty, died here January 26, aged 87.——Dr. S. Weir Mitchell delivered a lecture on "Lecturers," at Johns Hopkins, January 27.——Dr. Louis McLane Tiffany has gone to Florida on a hunting and fishing trip.

Hospital Report.—The annual meeting of the South Baltimore Eye, Ear, Nose and Throat Hospital was held January 25. During the year 2,065 patients were treated, white 1,917, colored 148; 10,878 visits to hospital and dispensary were made; 643 surgical operations were performed. A new site has been purchased for $13,000, consisting of a lot 90 by 200 feet, improved by a large brick residence.

The Dispensary's Work.—At the annual meeting of the board of directors of the Northwestern Dispensary the secretary reported 8,031 new patients, namely, 4,230 white and 3,801 colored; 1,166 patients were visited at their homes, and the total number of patients treated was 20,346. In the eye department 236 operations were performed; in the ear department, 51; in the nose and throat department, 30; in the surgical department, 134, and in the gynecologic department, 950. The following officers were elected: President, Dr. Arthur Wegefarth; secretary, Dr. Alexander D. McConachie; treasurer, Mr. William J. Klug; executive committee, Drs. A. D. McConachie, Frank A. Persohn and J. F. Travers.

MASSACHUSETTS.

Half Have Public Water Supply.—The State Board of Health has reported to the state senate that 172 of the 333 cities and towns of the state have now public water supplies.

Medical Inspection of Schools Demanded.—Another bill has been introduced into the state senate which authorizes the State Board of Education to provide medical inspection in all schools, such as is now provided by many cities and towns.

Brigham Will Valid.—The Supreme Court of the state has approved the validity of the will of Peter Bent Brigham, whose estate now amounts to $6,000,000, and unless the heirs carry the case to the United States Supreme Court this money will soon be applied to found and maintain a hospital for the poor, according to the terms of the will.

Medical Student Dies.—The dangers of medical practice or even study are exemplified in the sudden death of Joseph H. Converse, a student of Harvard Medical School. In the course of his work he exposed himself to cerebrospinal meningitis at the Boston City Hospital and within thirty-six hours of the first appearance of symptoms died from the disease.

Dispensary Report for 1904.—Reports from the 14 district physicians and the house staff of the Boston Dispensary shows that 93,578 patients were received at the dispensary during 1904, and 19,977 visits made at houses. They cordially commend the work of the nurses of the Instructive District Nurses' Association who work under them. Urgent need of new buildings is felt and efforts are being made to raise $100,000 for this purpose.

Embalmed Steak.—Six market-men in Boston were each fined $100 for selling hamburger steak which had been treated by preservatives. Their conviction was based on investigations of Dr. Harrington of the State Board of Health, who detected sulphite of soda. Experiments made by feeding cats with meat so preserved demonstrated marked degenerative disease of the kidneys and implies that this form of adulteration may be largely responsible for Bright's disease.

Would Abolish Noise and Smoke.—The topic of the annual meeting of the Association of Massachusetts Boards of Health, January 27, was "Noise." Prof. E. S. Morse read a paper on "Unnecessary City Noises;" Dr. Philip Coombs Knapp one on "The Effect of Noises on the Weak and Nervous," and Dr. James J. Patnam one on "A Comparison of the Different Sorts of Noises in Regard to Their Injurious Effect on the Nervous System." Strong resolutions were passed approving the bills now before the legislature for the abatement of the smoke nuisance in the metropolitan district.

Another Leper in Boston.—Another case of leprosy has been detected in Boston and the patient is quarantined on Gallop's Island. He is a Chinaman who has until recently been living in Newburyport. This makes four cases under care of the State Board of Health, three of whom, by courtesy of the Boston Board of Health, are quarantined on Gallop's Island, the fourth being in Harwich. The board has abandoned its plan to build a leper hospital on Cape Cod and has filed a petition with the state senate asking for a resolution calling on Congress to establish a national leprosaria.

Long Island for Chronic Diseases.—Dr. William T. Councilman of Harvard Medical School proposes that Long Island, in Boston harbor, be devoted exclusively to the care of chronic cases of disease. There is at present on the island a hospital of 300 beds. By removing the paupers now housed on the island their dormitories could readily be remodeled into wards to care for 400 other chronic invalids, and additional buildings erected and maintained at moderate expense. The main purpose of this change would be to furnish some adequate care for tubercular patients, a class now almost wholly neglected by the city authorities.

Milk Inspection Efficient.—To fill the place of Dr. Charles Harrington, who has succeeded Dr. Samuel W. Abbott as secretary of the Massachusetts State Board of Health, James O. Jordan has been appointed inspector of milk for Boston. So efficient has the work of this department become that there are a number of places in the city where milk comes by the carload daily, and where only a sample shows more than the 500,000 bacteria per c.c. allowed by the law, which went into force last June. Repeated warnings have been sent out and from this time on prosecutions will be started against violators, whether contractors, pedlers or shop keepers.

Deaths of the Last Fourteen Weeks.—Boston had during the ten weeks ended January 14, 2,060 deaths reported to the Board of Health, as against 2,077 during the same period a year ago, and an average death rate of 17.42 per 1,000 per annum. The report for the last week in 1904 was unusually low, as only 169 deaths occurred as compared with 231 last year, a rate of only 14.35 per 1,000. During this period of ten weeks there were reported 459 cases of diphtheria, with 45 deaths; 238 of scarlet fever, with 11 deaths; 145 of typhoid fever, with 31 deaths; 81 of measles, with 3 deaths, and 403 of tuberculosis, with 241 deaths. There were 322 deaths from pneumonia, 7 from whooping cough, 247 from heart disease, 82 from bronchitis, and 32 from marasmus. Of the fatalities 357 occurred in infants under 1 year old, 461 in those under 5 years of age, and 537 in individuals over 60.

NEW JERSEY.

Physician Injured.—Dr. Harry H. Sherk of Camden was severely injured as the result of his carriage colliding with an automobile, January 25.

To Combat Lodge Practice.—The physicians of Trenton have organized in order to break up the practice of treating lodge members and other organization people at contract rates. This method of treatment has become so general in Trenton as to warrant the step thus taken.

Hospital Report.—The annual report of the Camden City Dispensary shows that during 1904 1,266 patients were treated in the dispensary, 344 cases were treated at home, 1,933 visits were made to the dispensary, and 1,861 visits were made to residences; 10,664 prescriptions were dispensed.

Medical Society Election.—At the annual meeting of the Gloucester County Medical Society the following officers were elected: Dr. E. Mortimer Duffield, Glassboro, president; Dr. C. Frank Fisler, Clayton, vice-president; Dr. George E. Reading, Woodbury, secretary and treasurer, and Dr. W. Grant Simmons, Swedesboro, reporter.

NEW YORK.

Report on Niagara River Water.—Dr. Walter A. Scott, health officer of Niagara Falls, reported 288 cases of typhoid fever in the last year. Of this number 29 died of the disease. Of 266 medical cases in the Memorial Hospital 156 were typhoid fever. He classed Niagara River water as unfit to drink.

Stony Wold Sanatorium.—At the annual meeting of the officers of this sanatorium, which is located at Lake Kushaqua, in the Adirondacks, and was incorporated for the treatment of incipient tuberculosis of women, young girls and children, it was reported that 131 cases had been cared for since 1901, some staying over a year. It is the object of the institution to reach self-respecting persons who do without treatment rather than seek aid. There is the usual complaint that there are more to be cared for than present facilities can accommodate.

Care of Crippled and Deformed Children.—The fourth annual report of the New York State Hospital for the Care of Crippled and Deformed Children for the year ended Sept. 30, 1904, gives the following classification of diseases: Hip-joint disease, 16; white swelling, 3; major deformities of infantile paralysis, 5; Pott's disease of the spine, 4; congenital dislocation of the hip, 5; bowlegs, 2, and clubfoot, 7. Of these patients 17 were discharged; 5 of them were cured, 7 much improved, 3 as improved, 2 unimproved. There remained 25 in the hospital; of these 1 has congenital hip dislocation, 11 have hip-joint disease, 4 Pott's disease, 2 white swelling of the knee, 4 deformity from infantile paralysis, 2 bowlegs, 1 case of clubfoot. Of these patients 9 are girls and 16 boys. Out of the 42 cases treated 28 came from counties outside of New York and Queens. A new hospital is to be built at West Haverstraw, Rockland County, to cost $50,000, on a site of 50 acres overlooking the Hudson River.

Bills Before the Assembly.—Among the bills before the legislature are the following: A bill prohibiting the sale of proprietary medicines in the state, unless an analysis or formula specifying ingredients contained is printed on the label of the bottle or package. False analysis or failure to place formula on the outside of package is made punishable by a fine of not less than $50 nor more than $500, or by imprisonment of not less than one month nor more than six months. A bill providing for the establishment of a hospital for the treatment of habitual drunkards and victims of opium, chloral, cocain and other narcotics in New York City. This new hospital is designed to take the place of the alcoholic ward at Bellevue Hospital. A bill providing for an investigation into the purchase of a farm at Comstock, Washington County, as a site for the new State Hospital for the Insane and for which an exorbitant price was paid. It calls for the enactment of a law that will protect the treasury and its charitable and philanthropic interests from future injurious contracts and purchases. Senator Elberg again introduced his bill to abolish the office of coroner in New York City. This bill has been drawn up by Drs. Stephen Smith, Harry R. Purdy, E. Eliot Harris and James Taylor Lewis, counsel for the State Medical Association. It has been submitted to and approved by the legislative committee of the New York State Medical Association. The present coroners' physicians may become members of the new board of medical examiners under the civil service rules. The board is to be headed by a chief medical examiner, who will be directly responsible to the health commissioner for the work of the board. The duties of the board will be strictly those of physicians, leaving the legal and suspicious cases to be dealt with by the district attorney's office. This bill provides that a full report of each case must be sent at once to the district attorney's office, which will bring such cases as warrant it before a city magistrate. At present a coroner may be taken from any profession or trade. The members of the proposed board will have to prove their fitness by passing a rigid civil service examination. The recent arrest of Coroner Jackson, charged with having offered a bribe of $200 to one of the assistants of the district attorney if he would so shape a case of abortion that it could not be presented to the grand jury, and the defendant would have to be discharged by the coroner, illustrates how the office may be abused at present and may aid the cause of this bill, which has been defeated on two previous occasions.

Buffalo.

The Boy Wonder Again in Trouble.—Anthony Weichert, known as "Antonius the Boy Wonder," recently released from the penitentiary having served one year for conspiracy in defrauding people by promising to heal by the laying on of hands, etc., was rearrested on the charge of practicing without a license and remanded to jail.

Personal.—Dr. Frederic C. Busch resigned as assistant surgeon of the Sixty-fifth Regiment, N. G. N. Y., and Dr. Marshall Clinton was appointed to take his place.——Dr. Edward C. W. O'Brien. surgeon to the Fire Department, is critically ill with influenza.——Dr. James E. King, instructor in obstetrics. University of Buffalo, will spend a year in New York City in study.

December Statistics.—The monthly report of the Department of Health for December shows an annual death rate of 15.06 per 1,000. The principal causes were consumption, 39; measles. 12; septicemia. 6; typhoid fever, 8; debility, 44; alcoholism, 5; cancer, 20; apoplexy, 25; dementia, 7; meningitis, 7; valvular disease of the heart. 33; pneumonia, 68; gastro-enteritis. 6: nephritis, 36. and violence 29.

New York City.

Research Chemical Laboratory.—The department of health has decided to establish a research laboratory in the new laboratory building which is being erected where food and drugs will be examined by competent men and studies in purity made which will be of universal interest.

Anti-Spitting Brigade.—At a mass meeting of Brooklyn boys, designed as a missionary meeting to spread information relative to the spread of tuberculosis, an anti-spitting brigade was formed, with Dr. Darlington's approval, who announced on this occasion that Brooklyn was to have a new health department building.

Diphtheria on Staten Island.—There were 40 cases of diphtheria reported from Elm Park in a little over twenty-four hours. and an epidemic is feared. One public school has been closed. The health authorities say that a serious epidemic need not be feared as at this time last year there were 97 cases reported in the same period.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended January 20, 1905, 404 cases of tuberculosis. with 153 deaths; 360 cases of diphtheria, with 40 deaths; 289 cases of scarlet fever, with 14 deaths; 194 cases of measles, with 4 deaths; 179 cases of varicella; 50 cases of typhoid fever, with 12 deaths, and 30 deaths from cerebrospinal meningitis.

Effects of the Blizzard.—As a result of the severe weather there were six deaths from exposure and twenty street accidents, three of which were fatal. Cases of frostbite were treated by the hundreds at the various hospitals. The ears and hands of nearly two thousand of the street cleaners were frozen. The lobby of the Metropolitan Opera House was converted into a species of emergency hospital, where for a time policemen escorted those suffering from frostbite.

Work of the Pneumonia Commission.—Four additional workers have been added to the pneumonia commission. Dr. Norris of Bellevue has begun a series of experiments to determine how commonly the pneumonia germs are present in the air passages of persons who have died of some other disease and whether they are present in the air passages of persons who are killed when in good health. They are also experimenting in fifty different public school buildings in this city on methods of cleaning and the dust danger.

Not Pneumonic Plague.—The Red Star steamer *Vaderland* was sent back to quarantine by Dr. Doty. health officer of the port. because eleven deaths occurred in one compartment during the passage. The deaths were ascribed to pneumonia. but it was feared that the disease might be pneumonic plague. although this disease has heretofore only come from India. Bacteriologic examination failed to show the presence of anything other than ordinary pneumonia. and after thorough dis infection the passengers will be allowed to land.

Radium Cure Swindle.—The New York County Medical Society. with the assistance of a woman detective. have succeeded in having "Dr." H. H. Kane and his associates, "Drs." William H. Hale and William F. Horton, arrested and indicted on the charge of having swindled a carpenter out of $10.000. They claimed that his life could be saved by radium. and pretended to have used that drug. The alleged radium tube was analyzed at Lederle Laboratory. and found to contain ginseng, strychnin and a few other drugs found in most tonics, but no radium. There are a number of cases against these men by persons who have been swindled out of sums ranging from $100 to $2,500. They have been practicing under state licenses. The counsel for the county medical society secured an injunction restraining banks holding deposits of the men from paying out any money, and it is probable that some of the victims may be reimbursed.

Hospital News.—The proceeds of the German Charity ball. amounting to about $12,000, will be distributed among the German hospitals of the city.——Isaac Guggenheim has contributed $1,000 to Sydenham Hospital and has agreed to give monthly an amount equal to such sums as the board of directors succeed in raising through gifts up to and including the sum of $10,000 each year.——The plans have been filed for the new building of the Manhattan Eye, Ear and Throat Hospital, which is to be erected in East Sixty-third Street. The building will be twelve stories high, will accommodate about four hundred ward patients and fifty private patients. A feature of this hospital is its postgraduate department.——The New York Foundling Hospital has lost its case against eighteen citizens of Clifton, Ariz. The authorities of the hospital endeavored to recover children who had been placed in families in Phoenix, Ariz., by three sisters of charity. The Supreme Court has unanimously decided that as the children have homes, their best interests have been subserved. The attorneys for the petitioner preferred an appeal to the United States Supreme Court.

PENNSYLVANIA.

Personal.—Dr. Oscar Kniffler. Pittsburg, has moved to Göttingen, Germany, and will eventually settle in Wiesbaden.——Dr. Reinoehl Knipe, Norristown, has been re-elected physician to the Montgomery County prison.

Large Sum Asked for Charity.—The State Board of Charities in its biennial report recommends that $9,406,923.75 be appropriated to the state, semi-state and private institutions in the state for 1905 and 1906. The report stipulates that $7,227,804.10 shall be applied for maintenance, and that $2,179.119.65 for building. The total amount applied for by the various institutions throughout the state was $15,033,462.09, of which $8,947.264.34 was for maintenance and $6,086,197.75 for building. The board also recommended that $2,000,000 be appropriated for the maintenance and clothing of the indigent insane for the two years beginning June 1, 1905; that $50,000 be appropriated for the erection of an institution for the criminal insane on the grounds of one of the existing penitentiaries. In all 119 asked aid and 17 applications for assistance were disapproved by the board.

Crusade of Education Against Consumption.—The free lectures on consumption to be delivered under the auspices of the Henry Phipps Institute are now going on. The movement also will be started in the towns circumjacent to Philadelphia. Dr. Horace Cairncross of the Phipps Institute lectured before the Glassblowers' Union in Woodbury, N. J.. on this subject, January 27; Dr. Ward Brinton lectured to the textile workers on "The Home Treatment of the Disease," January 28, and Dr. Daniel J. McCarthy delivered a lecture on "Tuberculosis" in Oil City, February 1. Dr. McCarthy also lectured on this subject in the Deaconesses' Home, Philadelphia. January 25. Dr. Lawrence F. Flick of the Phipps Institute said that the institute is for the study. treatment and prevention of tuberculosis, and these lectures constitute one part of the educational side of the work. The lectures, he said. were requested by the lay organizations and this shows an enlightened interest in the subject, and that people are looking for truth in the matter.

Philadelphia.

Malpractitioner Sentenced.—Mrs. Elizabeth Ashmead. who was committed to jail by the coroner March 30, charged with malpractice, and who was recently found guilty, was sentenced on January 26 to three years in the penitentiary from date of commitment.

New Society Officers.—The Philadelphia County Medical Society, at its annual meeting January 18. elected the following officers: President. Dr. James M. Anders; vice-presidents. Drs. M. Howard Fussell. Alfred M. Eaton, Hilary M. Christian. Franklin Brady and Milton B. Hartzell; secretary, Dr. William S. Wray: assistant secretary. Dr. Ross H. Skillern; treasurer, Dr. Collier L. Bower. and censor, Dr. Judson Daland.

Personals.—Dr. Samuel Bolton was thrown from his sleigh in a runaway and sustained a slight concussion of the brain. He is slowly recovering.——Dr. John H. Jopson was recently elected to the surgical staff of the Presbyterian Hospital.——Dr. Milton J. Rosenau of the United States Public Health and Marine-Hospital Service, and director of the Hygienic laboratory at Washington, delivered a lecture at the Medico-Chirurgical College January 27 on "Tropical Anemia, with Special Reference to the Hookworm in Tropical Malaria."

Health Report.—The total number of deaths reported for the week aggregated 499. This is a decrease of 20 from those of last week, and a falling off of 63 from the corresponding period of last year. The deaths from pneumonia numbered 67, an increase of one over the previous week. There was a notable decrease in the number of diphtheria cases. In all 62 were reported, 33 less than last week. The principal causes of death were: Typhoid fever, 11; tuberculosis, 40; cancer, 12; apoplexy, 20; heart disease, 58; acute diseases of the respiratory tract, 155; enteritis, 23, and Bright's disease, 46. The total number of contagious disease cases aggregated 207, with 21 deaths, as compared with 231 cases and 24 deaths for the preceding week.

Free Public Lectures on Hygiene.—The Department of Medicine of the University of Pennsylvania has announced a series of free public lectures on the subjects of hygiene and medicine of general interest to practitioners and the public, to be delivered on Monday afternoons in the medical laboratories. This course was arranged especially for the fourth-year students, but invitations to attend the lectures are extended to the members of the medical profession of the city. Dr. Leonard Pearson, dean of the veterinary department, will deliver the first two lectures, February 6 and 13, on "Milk Supplies of Cities." On February 20 Dr. Jay F. Schamberg will speak on "Vaccination," and on February 27 will give a demonstration on the subject of "Eruptive Fevers." On March 6 and 13 Dr. Edward C. Kirk, dean of the dental department, will speak on "The Medical Relationship of Certain Dental and Oral Disorders." On March 20 Dr. A. P. Francine will speak on "The Restriction and Prevention of Pulmonary Tuberculosis." On March 27 Dr. R. Tait McKenzie, director of physical education at the university, will speak on "The Therapeutics of Exercise." Dr. Joseph Sailer will deliver the two closing lectures April 3 and 10 on "Hydrotherapy."

Course in Public Health.—The University of Pennsylvania will introduce into its curriculum, beginning October 1, a course in public health which will include instruction under the following headings:

Sanitary Engineering.—Including the subject of water supplies, sewerage systems, street cleaning, disposal of waste, etc.

Sanitary Legislation.—A study of the movement for sanitary reform and of the laws enacted relating to public health, and the methods of enforcement employed in Great Britain and the United States.

Inspection of Meat, Milk and Other Animal Products.—The methods of preparation and preservation of the same, the conduct of dairies, creameries, etc., and demonstrations of the diseases of animals transmissible to man.

The Sanitary Engineering of Buildings.—Including demonstrations of systems of heating, ventilation, plumbing and drainage, the study of plans, etc.

Social and Vital Statistics in the United States.—An examination of statistical methods and their results, with special reference to vital statistics and to city populations.

Practical Methods Used in Sanitary Work.—Including water, air and milk analyses, studies in ventilation and heating, investigation of the soil, methods of disinfection, sterilization, etc. (This is purely laboratory instruction.)

General Hygiene.—As applied to the community, including lectures on the causation of disease—exciting and predisposing, methods of prevention—including isolation, quarantine, natural and acquired immunity, protective inoculation, vaccination and the antitoxic state, methods of house disinfection and the means employed, suggestions for the organization of sanitary work, the influence of water supplies and sewage disposal on the public health, etc.

Personal Hygiene—Including the physiology of exercise, the adaptation of exercise to the various physical requirements, the use of exercise for the prevention and correction of deformities, the methods of examination and record keeping, the routine physical examination of growing children and the relation of air, food, bathing, etc., to health and development; the hygiene of the school room.

SOUTH DAKOTA.

Hospital Report.—Since its foundation in 1900, St. Luke's Hospital, Aberdeen, has cared for 845 in-patients, with 25 deaths.

Law Regarding Vital Statistics.—The legislature of South Dakota has passed a bill providing for the collection, preservation and publication of census and vital statistics and approprinting money for carrying this into effect. This is the first law in the state relating to vital statistics.

Compulsory Reports Recommended.—The Black Hills District Medical Association, which met at Deadwood, January 8, for its annual session, has proposed a bill advocating the compulsory report of all births and deaths under a penalty of $100 for failure, the physician making reports to receive a fee of 25 cents for each birth or death so reported. The following officers were elected: Dr. Adelbert H. Bowman, Deadwood, president; Dr. C. W. Hargens, Hot Springs, vice-president; Dr. Felix E. Ashcroft, Deadwood, secretary; Dr. Frank S. Howe, Deadwood, treasurer, and Dr. John W. Freeman, Lead, delegate to the state medical association.

GENERAL.

Yellow Fever on Naval Ship.—The U. S. cruiser *Boston* arrived at Panama from coast ports, January 25, with yellow fever on board. Two men are reported to have died, but no new cases have occurred beyond the seven reported first. The ship has been ordered north because of this occurrence.

Yellow Fever at the Isthmus.—The canal officials are reported to be taking extra measures to prevent the spread of yellow fever at the isthmus. They have a large problem to deal with, as the laborers and skilled employes, including women, who are arriving from the United States, are for the most part inexperienced and careless concerning tropical life and its dangers.

Dr. Kelly Asks for Material for Study.—Dr. Howard A. Kelly, 1418 Eutaw Place, Baltimore, writes that he is studying membranous dysmenorrhea, and says that since he is greatly in need of material, he will be indebted to any physician who will mail him casts of the interior portion of the uterus discharged by dysmenorrheic patients. The fresh specimen should be put in a bottle containing a 10 per cent. solution of formalin.

Pneumonia Rates of Chicago and New York.—The bulletin of the Department of Health of Chicago, compares the pneumonia mortality in New York and Chicago. For years New York has had a lower pneumonia rate than Chicago, but the recent increase there has temporarily reversed the conditions. In Chicago, in November, 1904, 260 deaths were reported from pneumonia, a daily average of 8.6. In New York, for the same month, 802 deaths from pneumonia were reported, a daily average of 26.7. In Chicago, during December, 451 were reported, a daily average of 14.5, while in New York 1,452 were reported, a daily average of 46.8.

Dr. Cushny Goes to England.—Dr. Arthur R. Cushny, for the past twelve years professor of pharmacology in the Department of Medicine and Surgery of the University of Michigan, has been made professor of pharmacology in the Medical Department of University College, London, as was announced in The Journal last week. Dr. Cushny graduated in arts and in medicine in the University of Aberdeen and then took up the special study of pharmacology with Professor Schmiedeberg at Strassburg, in whose laboratory he became privat docent. When Professor Abel left the University of Michigan in 1893 and went to John Hopkins, Dr. Cushny, whose research work had already attracted attention on account of its high degree of excellence, was called to Michigan to fill the chair of pharmacology. During his twelve years of residence in this country he has made many valuable original contributions to the science of his special subject. Some of his most important papers have been those bearing on the action of digitalis, caffein, spartein, saline cathartics and the atropin group. He has recently contributed to the *English Journal of Physiology* a series of researches on the physiology of, and the effect of medicinal agents on the action of, the kidney. He has made valuable contributions on the physiology of the mammalian heart and the interpretation of pulse tracings. His text-book on pharmacology received immediate recognition, and has already passed through several editions. In his departure from this country, America loses and England gains one of the most thorough scientific investigators in medical science.

CANADA.

Tuberculosis in Montreal.—Last year there were 634 deaths in Montreal from tuberculosis. It is expected that in the next few years the deaths from this disease may be materially decreased, owing to the work of the Montreal League for the Prevention of Tuberculosis, and to the adoption of stringent measures against people spitting on the streets and in public places.

An Association of Ex-House Surgeons of Toronto General Hospital.—Speaking of the reunion of the house staff of Toronto General Hospital of 1892-1893, Dr. Charles O'Reilly, the medical superintendent, said that since 1876 there had been 220 house surgeons in that institution, and of this number in the twenty-eight years but eight had died. The work of organizing an association of ex-house surgeons in connection with this hospital is progressing.

Typhoid Fever in Winnipeg.—The health authorities state that 135 deaths from typhoid fever were reported in Winnipeg during 1904, and Winnipeg has an estimated population of 75,000. The total deaths from all causes numbered 1,436. It is estimated that during the year over 2,000 cases of typhoid were reported. One of the Winnipeg newspapers counted 226 deaths reported from typhoid fever during 1904, as shown on the official register. This would make a rate of 3.01 deaths per 1,000 of population from typhoid, while the figures of the health authorities would make a rate of 1.8 per 1,000.

Personal.—Dr. J. F. W. Ross, Toronto, is spending the remainder of the winter in Southern California.——Dr. J. N. E. Brown, secretary of the Gold Territory, Dawson, has left Toronto to spend the next three months in Southern California.——Dr. George R. McDonagh, Toronto, has gone to the south of Italy, to remain three months.——Dr. W. H. B. Aikins, one of the editors of the *Canadian Practitioner and Review*, will spend the next three months in Vienna.——Dr. W. J. O. Malloch, Toronto, demonstrator of anatomy in the Medical Faculty of Toronto University, leaves March 1 for a two years' course in England.——Dr. Glen Campbell, Vancouver, B. C., has gone to Europe for a year's study.——Dr. Barrett of Dawson is visiting the hospitals of New York.——Dr. G. H. Manchester, medical superintendent of the New Westminster (B. C.) Insane Asylum, will resign and a new superintendent will be appointed March 1. Dr. W. T. Williams of St. Thomas, Ont., will go to the Bahama Islands shortly, having been appointed quarantine officer and medical health officer for the island of Inagua.

FOREIGN.

German Naturforscher Congress.—The German Naturforscher Congress is to meet this year at Meran, September 24 to 30.

Vaccination in the Ottoman Empire.—On April 18, 1904, a law went into force in Turkey making vaccination and revaccination compulsory.

French Congress of Climatotherapy.—The second French Congress of Climatotherapy and Urban Hygiene will convene at Arcachon April 24, and will adjourn to Pau for the closing meeting, April 29. The French railroads allow half-fare rates to members and their families. Dr. Dechamp, Villa Tibur, Arcachon, has charge of the arrangements.

Hirschberg's Anniversary.—Prof. J. Hirschberg of Berlin, the well-known ophthalmologist, recently received a *Festschrift* from his friends and pupils on the twenty-fifth anniversary of his professorship. It contains a number of works by prominent ophthalmologists of various countries. One of the cabinet ministers and delegates from a number of scientific societies were present at the ceremony of presentation.

International Congress of Anatomy.—The international committee representing the foremost societies of anatomy in the world, met at Geneva, December 20, and made arrangements for the first international federative congress of anatomy. The date was appointed as Aug. 7 to 10, 1905, with Geneva as the place. Cristiani and Batelli of Italy are members of this committee. Romiti of Pisa is the official delegate.

Results of Antimalaria Campaign on Roman Campagna.—In the official annual report of the Red Cross, which has charge of this work, we note that 11,962 persons received prophylactic quinin treatment and only 67 exhibited primary malarial fever. There were 313 cases in which malaria recurred in persons formerly subject to it. This is a total of only 380 cases in one of the worst hotbeds of malaria in Italy.

Life Insurance of Children Forbidden in France.—The Académie de Médecine of France and the Société Royale de Médecine of Belgium have proclaimed the abuses liable to follow the insurance of the lives of infants and children. Communications were presented before these bodies showing the evil results of this custom, which seems to be widely prevalent in northern France. The French government has enacted a law which prohibits all insurance payable at the death of children under 12.

Opening of the Vegetarian Orphan Asylum.—Berlin declined the legacy left by Baron, a member of the law faculty at Bonn, for the erection and maintenance of a home for destitute children to be conducted on vegetarian principles. The city of Breslau offered to accept it, basing its acceptance on Flügge's statements that the small amount of meat which the poor are able to afford can be effectually substituted and surpassed by milk and eggs. The asylum is now complete and was recently inaugurated.

Campaign Against Irregulars in Germany.—The medical profession in Germany has been conducting a more or less well organized campaign against irregulars for the last few years. Germany has been made too hot for many of the latter, and recent letters from Switzerland complain that they are flocking into that country. We mentioned in these columns recently the bold attempt made by the irregulars located at Zurich to influence legislation to allow them a free hand. The matter was decided by popular ballot and the measure was defeated by a large majority. One of the most potent means used by the profession in Germany in their campaign is what they call "press committees." A number of the large cities now have these committees, and the one at Munich has been in operation since 1901. It was founded by Cramer's efforts, and consists of nine physicians, who are thoroughly posted and ready writers. Medical meetings, etc., to which the lay press was in the habit of sending a reporter, were written up by a member of the committee and copies were sent to the newspapers. The latter were urged to refer to the committee all copy relating to medical matters, dubious ads, etc., and the press clipping bureaus kept the committee posted on what might otherwise escape them. The newspapers consented to this arrangement, and co-operated in most instances with the committee. Excellent results have been obtained in the matter of swindling advertisements. Many of them were discontinued by the papers on the recommendations of the committee. Others that were still carried were accompanied by a warning in the editorial pages. The committee investigated the standing of irregulars and wrote them up for the papers, and when criminal or other proceedings were instituted against them the committee sent in articles discussing the case and emphasizing its instructive points. A member of the comtee was also appointed to attend the assemblies of irregulars, to join in the discussions and to report the meeting for the newspapers. Dr. Max Nassauer's detailed account of the work of the Munich committee was published in the *Aerztl. Vereinsbl. f. Deutschland*, 1903, No. 498. An epitome of it is given in the last *Prag. med. Wochft.*, accompanied by an urgent appeal from Kantor for the organization of a similar committee in Bohemia. The idea is for each town and county to form a network of similar committees to unite for a common campaign against irregular practices. The Munich committee did not hesitate to write up disparagingly the unethical advertising of one colleague, a lung specialist, and another who advertised his "ocularium" in an undignified manner. The prompt and solid organization of the profession in Munich when the troubles with the sickness insurance societies (*Krankenkassen*) were impending a year ago, was undoubtedly one of the results of the work of the press committee. The equally prompt acquiescence of the insurance societies in the just demands of their medical officers, forestalling their resignation, may likewise be attributed to the influence exerted on the public by the untiring labors of the press committees. The *Allg. med. Cent.-Ztg.* publishes each week the suits instituted against the irregulars throughout Germany. There are always at least two or three: they are brought for swindling advertisements or for cheating by selling medicines at prices altogether out of proportion to their cost, or for personal injury from their practices. The sentences are fines of from $10 to $300 and imprisonment for from a week to six months or even two years. The last issue brings an account of a suit brought by Dr. P. Manasse of Berlin against an editor, R. Gerling, who has championed the cause of the "nature healers," and at a public meeting at which Manasse was present, he denounced the medical profession, remarking that he considered the majority of physicians as capable of any crime, any treachery and any wickedness. The prosecuting attorney (*Staatsanwalt*) demanded the imprisonment of the speaker, as a money fine was not adequate punishment for such assertions. The defendant was sentenced to one month in prison and the costs of the suit, which were large, and he was ordered to publish the account of the proceedings in his own journal.

Correspondence.

Iodin-Carbon-Disulphid Inhalations in Respiratory Diseases.

Columbia, Ala., Dec. 3, 1904.

To the Editor:—In the *New York Medical Journal*,[1] April 25, 1896, Drs. Stovall and Twitty report results from the use of iodin-carbon-disulphid inhalations in respiratory diseases. I have tested the remedy in my practice and offer the results to the profession in the interest of a subject which is closely related to the welfare of all classes of people. The profession is slow to accept new theories or methods of treatment, but this treatment has proved in my hands a most useful agent in combating the various laryngeal, bronchial and pulmonary disorders; and physicians elsewhere, after testing its merits, have spoken in unmistakable terms with reference to its practical value.[2]

Professor Coromilas,[3] at a meeting of the Chicago Medical Society, gave his conclusions, reached after treating a test series of 66 cases by the hypodermic administration of carbon disulphid. The results were eminently satisfactory, enabling him to use the word "specific" in estimating the value of the compound. The following is a summary of his investigations:

1. The disulphid of carbon as administered by him has no disagreeable results.
2. Because of its parasitic, antizymotic, antiseptic and inoffensive action, it is capable of penetrating all tissues and in this manner cures tuberculosis.
3. It has a strong action against the bacillus of tuberculosis.
4. It should not remain unknown, but should take its place in therapeutics as one of the specifics of our time, capable of doing immense service to suffering humanity.

While I am disposed to discredit the use of the word "specific," yet the professor's conclusions are practically identical with my own, as well as with those previously enunciated by Drs. Stovall and Twitty. There can be no doubt of the value of the hypodermic administration of this preparation as a means of impressing the system, but as the professor claims that the disulphid is strongly antagonistic to the tubercle bacillus, it would seem reasonable to suppose that inhalation would be the most direct method of application in phthisis pulmonalis. My colleagues in this city advance this argument, in writing on the subject, claiming, as they do, the superiority of the direct method by inhalation. In my own opinion the addition of iodin, as they suggest, adds very much to the therapeutic value of the remedy; this combination precludes its use hypodermically and has an agreeable effect on the solution when used as an inhalant.

Because of the difficulty of performing intratracheal injections the services of a laryngologist are often required when this procedure is necessary.

It is not my intention to go into details appertaining to any particular phase of the subject, but rather to impress on the profession the great value of this new remedy, which, with hygienic measures, is of great assistance in battling against respiratory diseases. The physicians to whom I have referred as originators of the idea have given their experiences in detail in contributions to different journals, as well as having issued a pamphlet explanatory of the method. I will not consume time and space with clinical histories, but will say in conclusion that physicians who are interested in the treatment of respiratory diseases will do well to study closely this method of treatment, and that Drs. Stovall and Twitty will take pleasure in replying to any correspondence.

C. L. C. Atkeson, M.D.

[Editor's Note.—Dr. Atkeson does not give instructions nor technic regarding the use of this preparation. To remedy this omission we repeat the description which was quoted from Drs. Stovall and Twitty in The Journal, June 13, 1896: "We are quite positive that by deep inspiration the remotest recesses and apical caseations are reached. The good effects are manifest during the first day's trial, and the night cough which is so troublesome and exhausting is much improved; and this is among the first benefits derived. Expectoration is lessened in quantity and the quality is made decidedly better in a short time. The sulpho-carbon compound is put down as poisonous, and we have watched very closely for any untoward symptoms attributable to its inhalation, but, so far, have failed to note any objection to its use under proper precautions and directions from the physicians. About a 12 per cent. solution, or, more accurately, one of a dram of iodin to the ounce of disulphid, is what we have used in practice. (Later recommendation is as follows: The strength of the solution varies from 10 to 60 grains of iodin to the ounce, according to special requirements, deep-seated disease indicating a stronger percentage of iodin than does catarrh of the upper tract. The weaker solutions also admit of nasal inhalation as well as oral.) Owing to the solubility of rubber and kindred matter in the disulphid, it is rendered inadmissible as material for an inhaler, which should be made of glass preferably. A cheap, convenient instrument may be improvised by using a small test tube with a sponge in the bottom saturated with the liquid; it will be necessary to replace the sponge frequently, because of the corrosive action of the medicine. For lung and laryngeal treatment, the inhalation is to be made through the mouth with the instrument pushed far back, approximating the opening of the larynx. The frequency with which it may be used is variable according to the individual condition and effects; we may say, on an average, once every two hours during the day. The disulphid has a bad odor which is objectionable to some patients. We have experimented with a view to rendering it more agreeable and have made various additions and modifications, resulting with no advantage considerable enough to justify the use of anything additional, inasmuch as such a change might possibly lessen the practical value of the original formula. Menthol is perhaps the best harmless addition that we have attempted (15 grains to the ounce). We should be very glad if the profession would prove the efficacy of the treatment and report the results." Drs. Stovall and Twitty have since advised the use of the bent tube inhaler, known as the Giarth modification. They give the following directions for use: "The fluid is dropped to saturation on the gauze, avoiding using an excess; also being careful that it does not come in contact with the cork inserted in the end of the inhaler. When ready for use (mouth inhalation) hold the tube two or three inches from mouth, inhaling carefully, avoiding as far as possible the induction of violent fits of coughing which a too vigorous application of the fluid might produce. By beginning cautiously the patient will be more easily controlled and the sooner will become accustomed to its vigorous application. It is very necessary to know and to inform the patient that a few inhalations even may give rise to unpleasant sensations, such as vertigo, or fullness about the head, which should serve as a warning to stop inhaling until these sensations pass off. Usually the vertigo is only transient, and a few moments will witness a return to the normal state. As a rule, one can draw five or six deep inspirations, rest a short time and repeat. Unless the cough is too violent or other bad effects supervene, the patient may be allowed to repeat the inhaling act five or six times at one sitting. It is always advisable to have the patient in half reclining or sitting posture. Every four hours during the day is often enough, in the beginning, to take the treatment. As toleration is established, it may be advisable to use every two hours, if no contraindication presents itself."]

Insane Wards in General Hospitals.

Pittsburg, Pa., Jan. 27, 1905.

To the Editor:—In his interesting description of the new City Hospital of Nuremburg,[1] Dr. Barker mentions that 31 of its 946 beds are allotted to insane patients. One could wish that he had furnished some information as to just how this division of the hospital is equipped and how it is managed, for, in my opinion, the attempt to treat disease which exhibits "insanity" as a symptom or group of symptoms in a general hospital marks a distinct step in advance. It is an effort to follow out in practice the theory that "insanity" is a manifestation of sickness, as is headache or edema or convulsions or vomiting or paralysis, dependent, like any of these symptoms, on underlying bodily alterations. To treat "insanity" in a general hospital is an object lesson, to the profession and laity alike, of immense value. In no other way, I believe, is it so apt to be studied on a proper basis by physicians; and by no other method may we hope to do so much to combat the old idea of the laity that "insanity" is a curse or disgrace, and to teach them that it is one of many manifestations of bodily disease in which the brain shares. By no other plan are "insane" patients so apt to be brought early for hospital treatment. The plan has far more to commend it than that of pure psychopathic hospitals unattached to general hospitals, which by the laymen will doubtless be called "insane asylums" no matter how modern their methods, and to which the old-time stigmata will doubtless attach. For some ten years I have been one of the visiting physicians to the insane department of St. Francis Hospital of this city, and on the basis of this experience I have ventured the foregoing observations. I do not know of another general hospital in this country like St. Francis of Pittsburg with an insane department as an intimate part of a general hospital. I am convinced that much good would result if one or more hospitals in each large city of the country would provide wards (properly equipped, of course) for a few insane patients. Acute cases only should be taken. Theodore Diller.

ANTIQUATED TEACHING IN MEDICAL COLLEGES.

Philadelphia, Jan. 28, 1905.

To the Editor:—I have been much interested in the letter in The Journal, Jan. 28, 1905, p. 307. It is not necessary for the correspondent to make known his local habitation or his name. It is, indeed, a condition that confronts us, not a theory. Many a gray-haired college professor will recognize the picture, and say sadly, with Sir Andrew Aguecheek, "That's me, I warrant you." In the present rapid onward rush of scientific progress few, if any, teachers at the end of twenty years can represent the existing state of their science. The question, however, arises at once as to what constitutes up-to-date teaching. The charges that A. B. C. brings are not entitled to consideration unless itemized. It is easy for some junior to assert flippantly that "Dr. X. is an old fogy," and it is also easy to develop a spirit among students that will lead to murmurs against the senior teacher. Instructors, demonstrators and quiz teachers are brought into close personal relations with students and are often possessed of considerable personal magnetism. The desire to succeed to the chair may be very strong, and the medieval method of poisoning the "old man" being no longer available, the safer and often effective method of poisoning the minds of his pupils and his colleagues is carried out. The charge of the teaching being behind the times could be used to vacate the larger proportion of professional chairs. How many competent teachers of botany are still teaching that stamens and pistils are sexual organs? Yet the view is quite abandoned by many biologists. On the other hand, the periodic system in the classification of elements practically dominates chemistry to-day, yet Berthelot considers it as comparable in its absurdity to the views held by the alchemists. When I was a student at Jefferson College Dr. S. D. Gross, easily first among American surgeons, taught with great positiveness that soft and hard chancre are due to the same virus. He stood almost alone in this respect. His colleagues and his principal assistant knew his error, and knew the practical objection to the view, yet an effort to displace him on this account would have found very few supporters. I fear that from the very nature of the case your correspondent can not give us the data. The name and place, as I have said, are of no moment. We ought to have specific instances of shortcoming. Does the professor teach the uric acid theory of gout? Does he hesitate to accept the recent views as to the nature of the proteid molecule? Does he insist that some of the long-known vegetable alkaloids are as efficient as the popular coal-tar synthetics? You are right, Mr. Editor, in pointing out that the sore spot in A. B. C.'s college is in the weakness of the colleagues. What is the condition in a college when a respectful petition presented by students could lead to their expulsion? I fear that if the accused professor is not up-to-date in his science he is quite so in some of his business methods. It is not necessary to say that the college is not in Russia; in every large city in this country at least one representative of the type will be found. Henry Leffmann.

GRATUITOUS SERVICES BETWEEN PHYSICIANS AND DENTISTS.

X. says that he attended a dentist's wife and that the dentist objected to the bill for services, claiming at first that the charge was too large and later claiming that it is improper for physicians to charge anything for services rendered dentists. X. says he can not find that any of the physicians in his city have ever been treated gratuitously by physicians or have been in the habit of rendering gratuitous services to dentists. X. asks for information. In some localities physicians and dentists render services to one another gratuitously. The usual custom is to give a discount. X. also details the operations, etc., included in the services referred to, and asks if his charges were not very moderate. We prefer not to express an opinion, but to leave this point to be decided on the basis of the custom of the profession of X.'s city, both as to scale of fees and as to discounts, etc., to the dental profession.

LICENSE TO PRACTICE IS PERMANENT.

Hebbardsville, Ky., Dec. 27, 1904.

To the Editor:—Feb. 11, 1903, the State Board of South Dakota granted me license to practice medicine in that state. Since then they have passed some stringent laws. Have I the right to practice medicine under the license I hold without any further examination? L. O. Jones.

Answer.—Yes; although Section 22 of the medical practice act of South Dakota states specifically that the new act, which went into force March, 1903, is not applicable (among others) "to resident physicians and surgeons of this state regularly licensed and practicing in this state at the time of the taking effect of this act."

Marriages.

Charles H. Sherman, M.D., to Mrs. M. E. Herrington, both of Dallas, Texas, January 15.

Basil M. Taylor, M.D., to Miss Cora Bartlette Corte, both of Greensburg, Ky., January 18.

Henry T. Bray, M.D., to Miss Elizabeth V. O'Connell, both of New Britain, Conn., January 11.

George F. Paine, M.D., St. Louis, to Miss Dorothy Frye of Salida, Colo., at St. Louis, January 22.

George W. Crosby, M.D., to Miss Rosa Hall, both of Sheboygan, Wis., at Milwaukee, January 16.

J. Alexander St. Pierre, M.D., Three Rivers, Que., to Miss Blanche Barsalon of Montreal, January 26.

Bert Rodenbaugh, M.D., Barberton, Ohio, to Miss Grace Robinson of Youngstown, Ohio, January 3.

Romeo Roderick Stevenson, M.D., Sioux Falls, S. D., to Miss Emilie F. Avery of Chicago, January 25.

William A. Brock, M.D., Leesburg, Ky., to Miss Sallie E. Nichols of Silas, Ky., at Lexington, Ky., January 18.

Seth Marion Billings Smith, M.D., Crandon, Wis., to Miss Elizabeth Porter of Wausau, Wis., January 25.

E. Julius Boeber, M.D., Kansas City, Mo., to Miss Helen Moeller of Kiel, Germany, at El Paso, Texas, January 18.

T. Robert W. Wilson, M.D., Baltimore, to Miss Lillian B. Thackston of Greenville, S. C., at Baltimore, January 17.

Deaths.

William Harrison Jones, M.D. Howard University Medical Department, Washington, D. C., 1887, a prominent colored physician of Harrisburg; a member of the American Medical Association, and at one time president of the Harrisburg Academy of Medicine, died at his home in Harrisburg, January 19, from pneumonia, after a short illness, aged 46. At a special meeting of the Academy of Medicine, remarks eulogistic of the deceased member's private and professional life were made by Drs. Hugh Hamilton, Hiram McGowan, David S. Funk, John W. Ellenberger, John F. Culp and Jerome Z. Gerhard.

Cordelia A. Greene, M.D. Medical Department of Western Reserve University, Cleveland. Ohio, 1857. of Castile. N. Y., a member of the American Medical Association, New York State Medical Association, Wyoming County Medical Society and Physicians' League of Buffalo. died January 28 in the Presbyterian Hospital, New York City, a week after an operation.

Patrick J. McGrath, M.D. Northwestern University Medical School. Chicago, 1894, until a short time ago a member of the staff of the Manhattan State Hospital. Central Islip, Long Island, N. Y., and waiting orders to go to Panama as surgeon in the Canal Zone, was killed January 28 by falling from a sloop near his boarding place in New York City.

Francis D. Edgerton, M.D. College of Physicians and Surgeons in the City of New York, 1864. formerly president of the Connecticut Medical Society; consulting surgeon to Middlesex County Hospital; assistant surgeon of the Twenty-first Connecticut Volunteer Infantry during the Civil War, died at his home in Middletown, January 19, aged 67.

Otis Eugene Hunt, M.D. Berkshire Medical College, Pittsfield, Mass., 1847; for several years secretary of the South District Middlesex Medical Society, and president or secretary or a member of the Newton Hospital Medical Board since its foundation, died at his home in Newtonville, Mass., January 20, aged 82.

Richard Cheatham, M.D. Bellevue Hospital Medical College. New York City, 1877, a member of the American Medical Association; member of the Nashville Board of Health and city health officer for several years, died suddenly from cerebral hemorrhage, January 21, after a long period of ill health, aged 49.

Virginius G. Hitt, M.D. University of Virginia. Richmond, 1863, of Atlanta, Ga., for several years secretary of the Association of Surgeons of the Confederate Army and Navy, died in the Presbyterian Hospital. Atlanta, January 15, from organic heart disease, aged 63.

Edwin Hellyer, M.D. Long Island College Hospital. 1864. died at his home in Kensington. Philadelphia. January 16. from pneumonia. He served as surgeon in the National Guards Hospital during the Civil War. and was visiting physician of the Penn Widows' Asylum.

Joseph R. Duncan, M.D. Cincinnati. 1859. assistant surgeon of the Eleventh Iowa Volunteer Infantry and surgeon of the Forty-sixth Iowa Volunteer Infantry during the Civil War. died at his home in Crawfordsville. Ind., January 21. after a lingering illness, aged 77.

George Whitaker Reed, M.D. Vanderbilt University Medical Department. Nashville. Tenn., 1895. a member of the American Medical Association. postmaster at Biltmore. N. C., died January 10 at his home in South Biltmore, after a long illness, aged 46.

Samuel J. Weaver, M.D. Jefferson Medical College. Philadelphia. 1872. died suddenly at his home in Bethlehem. Pa., January 18. from angina pectoris, aged 54. Dr. Weaver was surgeon to the Lehigh Valley Railroad and coroner of Northampton County.

Frederick W. Richardson, M.D. Long Island College Hospital. Brooklyn. N. Y., 1885, acting assistant surgeon United States Army, formerly of St. Paul. Minn., died at Ligao. Albay. Philippine Islands, January 26, from accidental wood alcohol poisoning.

Edward Valencourt Deuell, M.D. University of Louisville, Ky., 1864. surgeon in the Army from 1863 to 1869. of Saratoga Springs. N. Y., died suddenly. January 20. while giving testimony in court at Saratoga, from cerebral hemorrhage. aged 63.

George C. McFarland, M.D. Rush Medical College. Chicago, 1863, surgeon during the Civil War. for many years proprietor of Oak Lawn Retreat, Jacksonville, Ill., died suddenly in his room in Jacksonville from heart disease, January 16, aged 64.

Joseph A. Cantrelle, M.D. Tulane University of Louisiana Medical Department. New Orleans, 1850. physician of the Howard Society during the yellow fever epidemics of 1857 and 1878. died at his home in New Orleans, January 19, aged 77.

Robert Murray Riddell, M.D. Manitoba Medical College. Winnipeg. and for two years a member of the house staff of Winnipeg General Hospital, died in that institution January 22 from typhoid fever. after an illness of two weeks, aged 38.

George Andrew Campbell, M.D. Faculty of Medicine of Queen's University, Kingston. Ont., 1859, deputy inspector-general of hospitals and fleets. Royal Navy, died at his home in Ealing, near London, England, January 16, aged 68.

Jacob W. Lowman, M.D. Medical College of Georgia, Augusta, 1858, some-time representative in the legislature from Lexington County, S. C., died at his home in Orangeburg, January 15, after a prolonged illness, aged 68.

Joseph A. O'Neill, M.D. Albany (N. Y.) Medical College, 1897, acting assistant surgeon United States Army, was killed during an attack of ladrones on the town of San Francisco de Malabon, Philippine Island, January 24.

Thomas M. Weadock, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1872, a member of the Allen County (Ohio) Medical Society, died from cholemia at his home in Lima, January 20, aged 66.

Phineas S. Rose, M.D. Albany (N. Y.) Medical College, 1863, surgeon of the One Hundred and Seventy-ninth New York Volunteer Artillery in the Civil War, died at his home in Pasadena, Cal., January 19, aged 66.

Robert Wolfgang Schoenle, M.D. University of Louisville Medical Department, 1890, formerly of Seattle, Wash., died at Pasadena, Cal., January 24. from tuberculosis, after an illness of several years, aged 36.

Nathaniel Stacy Tafft, M.D. Cincinnati, 1852, who served several times in the state legislature, and was the oldest practitioner in Wabasha County, Minn., died at his home in Plainview, January 21, aged 74.

Alfred M. Bird, M.D. Illinois State Board. 1878, twice alderman and twice mayor of Mason City, Ill., died at his home in that city, January 25, from cerebral hemorrhage, after an illness of one year, aged 62.

Augustus J. Hofling, M.D. Miami Medical College. Cincinnati. 1899. secretary of the West End Medical Association, and district physician, died at his home in Cincinnati, January 22, from diabetes, aged 47.

James C. Bowser, M.D. McGill University Medical Department. Montreal, 1883, died at his home in Rexton, N. B., Canada, January 12, from consumption, after an illness of three years, aged 45.

Harry W. Spence, M.D. Toronto University Medical Faculty. 1898. M.R.C.S. England, who served with an English regiment in the South African War, died at his home in Ottawa, Ont., January 24. aged 29.

William M. McKemy, M.D. Bellevue Hospital Medical College. New York City. 1891, died from the effects of a self-inflicted bullet wound through the lungs, at his home in Pecos, Texas, January 23.

John B. Fuller, M.D. Texas Medical College and Hospital, Galveston. 1874, died at the house of his son in Jacksonville, Texas, January 18, after a prolonged period of ill health, aged 78.

Thomas Lafayette Lafon, M.D. Jefferson Medical College. Philadelphia, 1885, died at his home in La Grange. Mo., January 25, from consumption, after an illness of five years, aged 41.

Henry F. Hendrix, M.D. St. Louis Medical College. 1874, a strong advocate of hydrotherapy in infantile disease, died at his home in St. Louis, January 29, from cerebral hemorrhage, aged 61.

Storrs Hall, M.D. Medical Institution of Yale College. New Haven, Conn., for many years a practitioner of Rosendale, Wis., died at the home of his son in Ripon. Wis., January 13 aged 90.

Eugene S. Rice, M.D. New York City. 1879. coroner of Fountain County, died at his home in Wallace. Ind., January 14. from injuries received in a fall three days before, aged 4[illegible].

Jonathan Nichols, M.D. Albany (N. Y.) Medical College, 1848. a pioneer resident of Atlantic. Iowa. died at Los Angeles, Cal., from hypertrophy of the heart. January 17. aged 78.

Mark Harrison Ragsdale, M.D. Medical College. Indianapolis, 1875. of Alfordsville, Ind., died at the home of his son in Washington, Ind., January 14, from pneumonia. aged 68.

G. Granville Faught, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1879. died suddenly at his home in Philadelphia, January 25, aged 52.

James R. Brewer, M.D. Vanderbilt University Medical Department. Nashville, Tenn., 1878, a pioneer of Muskogee, I. T., died Dec. 30, 1904, at Santiago, Cal.

Joseph A. Anthony, M.D., a veteran of the Mexican War, died January 20 at his home in Terrell, Texas, from the effects of a fracture of the hip, aged 77.

Henry Ullyot, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1869, died at his home in Elmira, Ont., January 18, from pneumonia, aged 61.

Edward Howard Craven, M.D. Jefferson Medical College, Philadelphia, a retired physician, died at his home in Philadelphia, January 19, aged 82.

Frank McCormick, M.D. Toledo Medical College, 1895, of Fremont, Ohio, died at the home of his sister in Muncie, Ind., after a long illness, aged 53.

Reginald Percy Vivian, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1900, died at his home in Barrie, Ont., Dec. 8, 1904, aged 30.

Hugh B. McConnell, M.D. Trinity Medical College, Toronto, Ont., 1891, of Boston, died at his home in West Somerville, Mass., January 25, aged 34.

Wesley R. Davis, M. D., a retired physician of Stephens City, Frederick County, Va., died January 26 at Memorial Hospital, Winchester, Va., aged 60.

Eli W. Free, M.D. College of Physicians and Surgeons, Baltimore, 1847, died at his home in Baltimore, January 27, from heart disease, aged 80.

Lyman Wells Ranney, M.D., retired, died at his home in New Castle, Pa., January 12, from the effects of morphin taken accidentally, aged 85.

W. J. Dobbins, M.D. 1844, a practitioner of California in 1850, died at his home in Vacaville, Cal., January 3, from kidney disease, aged 81.

Archibald S. Kirkland, M.D. University of the Victoria College, Coburg, Ont., 1869, died at his home in Collingwood, Ont., Dec. 9, 1904, aged 60.

John W. Futrell, M.D. University of Louisville, Ky., 1872, died at Shawnee, Okla., January 20, after an illness of a year, aged 53.

Frank B. Jones, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1872, of Petersburg, Mich., died recently.

William Jackson, M.D. Chicago, 1891, died at his home in Climax, Mich., January 14, after an illness of three days, aged 59.

Albert Ellison, M.D. New York University, New York City, 1888, died at his home in Benton Center, N. Y., Dec. 20, 1904, aged 45.

Charles G. Sprague, M.D. New York, 1880, of Omaha, died at his farm near Leroy, Neb., after a long illness, January 18, aged 66.

Arthur Toal, M.D. Detroit College of Medicine, 1887, died at his home in Peck, Mich., January 24, from angina pectoris, aged 49.

Henry M. Flanigan, M.D. Philadelphia, 1875, died suddenly from heart disease at his home in Penn's Grove, N. J., January 9.

John F. Heinze, M.D. Missouri, 1878, died at his home in St. Joseph, Mo., January 20, from cerebral hemorrhage, aged 76.

Horace G. Anderson, M.D. Iowa, 1881, died suddenly at his home in Nathrop, Colo., January 11, from nephritis, aged 46.

John W. McAllister, M.D. Medical College of Indiana, Indianapolis, 1895, died at his home in Idaville, Ind., January 20.

John B. Brooker, M.D. New York City, 1894, died at his home in Mayfield, N. J., last week, after a long illness.

William Grant Mitchell, M.D. Guy's Hospital, London, England, died recently in Victoria, B. C., aged 37.

Charles C. Olmsted, M.D. Ohio, 1860, died at his home in Kansas City, Mo., January 25, aged 65.

Davidson Macdonald, M.D. Toronto School of Medicine, 1873, died in Toronto January 3.

Christian A. Hermann, M.D. Illinois, 1894, died at his home in Chicago, January 22, aged 59.

Death Abroad.

N. Sklifossovski, M.D., one of the leading surgeons of Russia, and president of the International Medical Congress at Moscow in 1896, died December 12 at his country home, aged 68. The list of his contributions to the literature is a long one.

Book Notices.

Mental Defectives; Their History, Treatment and Training. By Martin W. Barr, M.D., Chief Physician Pennsylvania Training School for Feeble-minded Children, Elwyn, Pa. Illustrated by 53 Full-page Plates. Cloth. Pp. 368. Price, $4.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

This book is based on knowledge and extensive experience. It is encumbered by no fads, and is biased by no pet theories; it is the product of a well-balanced mind and is a safe guide. Strictly speaking, it can scarcely be called a medical work, still no neurologist, alienist, or physician having to do with feeble-minded or defective children can afford to be without it. But the medical man does miss a chapter on pathology. He has learned to think of disease in terms of pathologic processes if not of pathologic anatomy. With the clinical picture he correlates a vision of abnormal tissue or deranged function. And this is well. To read a book, then, of more than three hundred pages on the mentally defective and find nothing of the causative brain conditions gives the physician an acute feeling of incompleteness. In his preface the author states that the work "addresses itself primarily to anxious parents and to earnest teachers." For the latter, meaning teachers of defectives, it is invaluable. So far as we are aware, there is no work in any language which can take its place. For the average parent the book is much too complete, too technical, too erudite. To sift from the mass the particular facts and advice applicable to his own child would require a layman of unusual education and intelligence. The different chapters are of most unequal value. Chapter 2 on history is very complete (53 pages) and would make a fitting introduction to a work three times the size of this one. The chapter on training and treatment is particularly good, but it might well be two or three times as long. There are well-considered chapters on craniectomy and asexualization, cretinism, microcephalus and hydrocephalus, and epilepsy. The author has seen fit to introduce a chapter on echolalia, one on adenoma sebaceum and one on Samuel Henderson, murderer—all reprints of published articles which properly have no place in this volume. They are simply padding, good padding, but padding none the less. Sixty-four pages are devoted to condensed statements of illustrative cases. They are very good and serve excellently well as sketches of types. There are about 135 of these cases and there is a half-tone reproduction of a very good photograph of each patient, but the arrangement of the pictures is abominable. The text is pages 249 to 313, the pictures are scattered through the book from page 36 to page 308. There are no cross references, so that a considerable search is necessary to find illustration going with description and vice versa. The defects are superficial, the excellencies are fundamental, and the work is sincerely commended to all interested in the subjects it covers.

Pneumonia and Pneumococcus Infections. By Robert B. Preble, A.B., M.D., Professor of Medicine, Northwestern University. Illustrated. Cloth. Pp. 211. Price, $1.00. Chicago: Cloyd J. Head & Co. 1905.

This monograph of 211 pages is timely. When pneumonia is destroying annually, in some parts of our country, more lives than tuberculosis, when new facts concerning its diagnosis and pathogenesis are being brought to light, and when confusing, conflicting, muddled and extravagant views are held as to treatment, it is well to have a résumé of the facts brought to our attention. This has been done by Preble. If one looks here for the latest views concerning the bacteriology of the pneumococcus, for the finer histologic details of the diseased lung or for the latest theoretic and experimental work on pneumonia along the line of Ehrlich's side-chain theory, he will be disappointed. And we take it the omission is made because the book is intended for the general practitioner and not for the expert, for the research man nor for the original investigator. Preble emphasizes the value of early blood examinations in suspected pneumococcus infections; the importance of paying attention to slight and atypical symptoms in the diagnosis of pneumonia; and above all to the inexcusability of an error in diagnosis made because of failure to examine the chest. The influence of the book as regards therapy will be good. We are a little disappointed that treatment does not receive more attention and that more details as to drugs, remedial measures, diet and nursing are not given. But the introductory remarks on the subject of treatment, regarding the uselessness or even harmfulness of giving the so-called specifics are well put and should do much to discourage the reckless though well-intended maltreatment by overdrugging. Statistics concerning therapy, unless they be carefully and scientifically compiled, are almost worthless. As Preble well says: "A judicious selection of cases will enable one to have a mortality at any desired point between 2 or 3 per cent. and 100 per cent." There is a healthful skepticism, not pessimism, about Preble's therapy that will do good in many quarters. While most of the facts are the old, familiar ones, some are emphasized and have attracted our attention because they are not always as clearly recognized as they should be. As illustrations we might mention the importance of making bacteriologic cultures from the blood; the possibility of recovery from pneumococcus meningitis; the aid to diagnosis from lumbar puncture in suspected meningitis complicating pneumonia; the distinctness with which bronchial breathing is heard by the direct method as compared to mediate, i. e., stethoscopic, auscultation. The points made regarding the value of the three symptoms, sudden onset with chill and high fever, herpes and leucocytosis as significant of pneumococcus infection (with or without pulmonary localization) are worth consideration and more extended observation. There is not, we think, enough emphasis laid on the probable conveyance of pneumonia from patient to patient by means of sputum, by coughing, etc., nor to the proper disposal of the sputum suggested under treatment. The alimentary symptoms, tympany, diarrhea, etc., deserve fuller mention. Post-pneumonic psychoses are not so rare that they should be passed unnoticed. The book is only in fairly attractive form. It could be improved in this respect. There are a few mediocre illustrations. There are not a few typographical errors —temperature for temptation, communis for commune, preturbatis for preturbatic, etc. From page 76 to the end of the book there are 33 lines to the page instead of 31 as found in the first 76 pages. While this, and other mechanical defects mentioned, do not seriously mar the book, they are blemishes that should not be allowed to pass without criticism.

DIET IN HEALTH AND DISEASE. By Julius Friedenwald, M.D., *Clinical Professor of Diseases of the Stomach in the College of Physicians and Surgeons, Baltimore;* and John Ruhräh, M.D., *Clinical Professor of Diseases of Children in the College of Physicians and Surgeons, Baltimore.* Cloth. Pp. 689. $4.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

This work discusses, first, the physiology and chemistry of digestion. In this relation the authors mention the quantity of food required for infants and adults under the various conditions by giving standard dietaries containing the important articles of food, with their relative food values expressed in heat units or calories. Mention is also made of the influence produced by different factors on digestion, such as the hours, order and frequency of meals, variety in diet, rest, and exercise before and after meals. The relative values of the different waters are also shown by their chemical composition presented in tabulated form. A small space is devoted to food adulteration. That part given to infant feeding includes the views and tables of the most important writers on the subject. The discussions on diet in diseases of the gastro-intestinal tract, circulatory system, genitourinary system, skin, etc., include the ideas of the leading authorities on these lines. The literature on the subject of diet has been thoroughly reviewed and so compiled and arranged in a systematic manner as to render it practical, simple and easily accessible to the physician. We believe the statement to be true that the instructions given to patients by the physician as to what should be included in, or restricted from his diet during treatment are, as a rule, not so definite and explicit as they should be. This book is of value in assisting the physician in outlining a proper diet list to meet the demands and needs of those cases which may require a special diet or a change in diet suitable to the different stages of the disease.

A DICTIONARY OF NEW MEDICAL TERMS, Including Upward of 38,000 Words and Many Useful Tables, Being a Supplement to "An Illustrated Dictionary of Medicine Biology and Allied Sciences." By George M. Gould, A.M., M.D., Editor of *American Medicine* Based on Recent Scientific Literature. Half Morocco. Pp. 571 Price, $5.00 net. Philadelphia: P. Blakiston's Son & Co. 1905

In the progress that is being made in medical science and in the sciences related to medicine new words must be coined to meet new conditions and new things. Gould tells us in the work before us that in a decade over 30,000 new terms have been devised, and this is believable, although he, of course, includes the terms covering all literature. The progress being made in experimental medicine, pathology, bacteriology, etc., makes new terms especially necessary, and those who desire to keep up find one of the stumbling blocks to be the new words that are in many instances meaningless. A critical examination of Gould's book shows that he has incorporated all new terms that relate to medicine, making it a valuable supplement not only to his "Illustrated Dictionary of Medicine," but to all other dictionaries. Not only have the new words been included, but old words which had become obsolete and which have now been revived are also incorporated in the book. The definitions in many instances are really descriptive in character and this adds to the value of the book. The lists of stains and tests are particularly worthy of commendation. This dictionary is commended to those who are anxious to be in touch with the progress which is being made and the literature pertaining to this progress.

THE PHYSIOLOGICAL FEEDING OF INFANTS. A Practical Hand Book of Infant Feeding, and Key to the "Physiological Nursery Chart." By Eric Pritchard, M.A., M.D. (Oxon.), M.R.C.P. (Lond.). Second Edition, Greatly Enlarged and Entirely Rewritten. Cloth Pp. 202. Price, $1.50 net. Chicago: W. T. Keener & Co. 1904

In this book, Pritchard emphasizes the impracticability of using one formula for all children. In the case of breast-fed infants he lays stress on the importance of regular meals for the mother as well as on the necessity of regular intervals between feedings for the child. Explicit directions are given for the preparation of artificial food and for modifying cow's milk, not only for infants but for sickly and delicate children The development and physiology of the infant is also given careful attention. The book is complete and practical.

PRACTICAL PHYSIOLOGICAL CHEMISTRY. By J. A. Milroy, M.A., M.D., Demonstrator of Physiology, Queen's College, Belfast, and T. H. Milroy, M.D., B.Sc., F.R.S.E., *Professor of Physiology, Queen's College, Belfast.* Cloth. Pp. 200. Price, $1.60 net. New York Longmans, Green & Co. 1904.

This is a practical, concise and intelligible book for the use of students. Methods of work and technic are alone considered. The proteids and proteid reactions are fully dealt with The chapters on the blood and on the urine are particularly good and should prove of value not only to students, but to general practitioners. Experiments are described fully, and there are numerous cross references which add to the value of the work.

Miscellany.

Annual Progress Number.—The last issue of the *Interstate Medical Journal* is the "Annual Progress Number," which reviews the medical literature of the past year. It contains several comprehensive and scholarly articles reviewing the progress made in all branches of medicine during 1904.

Charas Poisoning.—From Delhi, India, according to *Albany Medical Annals,* several cases are reported of poisoning by charas, a resin of cannabis indica. Eight Hindu prisoners in the jail became suddenly ill and confessed that they had managed to secure this drug, which they smoked in pipes. They vomited, complained of headache, nausea, giddiness and faintness of vision and of dryness in the mouth and throat. The conjunctiva was suffused and the pupils of all extremely contracted. The pulse was full and bounding and 120 per minute. One symptom was peculiar and noteworthy. While in a sitting posture the patient was constantly turning round and round from the left to right in a circular fashion. Ordinary remedies were resorted to and the patients were all right in the morning.

Encouragement and Sympathy for Patients.—Every practitioner of the highest position in surgery and medicine, said Lord Kelvin, addressing a body of physicians, has to administer spiritual consolation to his ptients. Do not run away with words and think I am encroaching on theological ground. When you keep up a patient's spirit you are administering spiritual consolation to him. Many a poor fellow, laid up with a broken leg in a splint, looks for the moment of the weary twenty-four hours when the physician gives him a kindly word, although only in passing. Let your natural feelings prompt you in your dealings with your patients and you can not go wrong, and you will be spiritual helps to your patients as well as physicians and surgeons. As men can not live on bread alone, patients can not get cured on drugs and splints alone.

Nomenclature of Synthetic Chemicals.—Pharmacists are frequently directed to dispense preparations about which they know absolutely nothing more than the fanciful name ending in al, en, ic, in or ol, says Golaz-Verey (in *Schweiz. Woch. f. Chem. u. Phar.*). The names usually consist of (1) some arbitrary abbreviation of the descriptive chemical title; (2) some real or imaginary reference to the possible therapeutic uses of the remedy; or (3) some fanciful and usually far-fetched discovery of the manufacturer. Pharmaceutic and medical societies should demand that manufacturers furnish information on (a) the commercial as well as the exact chemical constitution of the preparation; (b) reliable tests for identity; (c) melting and boiling points; (d) solubility; (e) special incompatibility; (f) dose and therapeutic action; (g) necessary precautions that are to be observed in keeping the preparation. If this really necessary information were forthcoming in all cases, new preparations might be dispensed and used with some prospect of a more rational advance in therapeutics.

Ocean Voyage for Invalids.—From the *British Medical Journal* we learn that a large sailing vessel will leave Great Britain about the end of January for a long voyage in the Atlantic in warm latitudes. It will carry about fifty tubercular patients and a number of inebriate and other invalids. The consumptives will live on deck in the open air night and day, constantly breathing absolutely pure air containing much ozone. During the voyage the vessel will call at such ports as Gibraltar, Canary Islands, Rio Janeiro, River Plate, Table Bay, St. Helena, Pernambuco, West Indies, etc. Time will be given to the passengers to see something of the countries and their peoples, and to learn something of their customs and manners. Everything will be done on board to make time pass pleasantly, music, games of all kinds, books, fishing and boat sailing when possible, and it is also proposed to teach a foreign language (French or Spanish). There will be an efficient staff of physicians and nurses. This example might be advantageously followed in this country. Many patients who shrink from sanatorium treatment would enjoy such a voyage and would be greatly benefited thereby. The countries visited and the novelty of life aboard ship would be of sufficient interest to keep the patient's mind diverted from his physical condition—a most difficult matter to accomplish in a sanatorium.

Imagination as a Cause of Death.—Two or three stories in British newspapers illustrate the powerful effect the imagination can exercise over the phenomena of life. The *Medical Press* reports that in one case a girl, suffering from despondency of spirits, is said to have swallowed some harmless fluid in mistake for carbolic acid. She immediately declared that she had poisoned herself, and soon died, though we are left without any information as to the nature of the equally peculiar case, a young woman asked a druggist for laudanum, but the clerk, noticing her excited condition, supplied port wine. Shortly afterward she was discovered apparently suffering from opium poisoning, and the usual anti-opium treatment was successful. Though we have no authority beyond newspaper currency for either of these stories, says the paper cited above, there is nothing in them inherently impossible. Apart from the extraordinary mimicry of which hysterical subjects are capable, there are several well-authenticated instances in which death has been the result of quite imaginary causes, or rather of the fright resulting therefrom. Perhaps the best known of these is the case of the janitor of a Scottish university, who, being threatened with being beheaded by a party of students, was made to kneel before an improvised block, and was struck on the neck with a wet towel. To the astonishment of the students, he did not move, and was actually found to be dead.

Effects of Borax and Boracic Acid on Health.—Dr. H. W. Wiley, chief of the bureau of chemistry of the Department of Agriculture, in his report (recently issued) of the experiments undertaken by the bureau to ascertain the effects of borax and boracic acid on digestion and health, gives some interesting information regarding the experiments. The persons volunteering were required to sign a pledge agreeing to follow implicitly the rules and regulations governing the "hygienic table" and to take no other food or drink—water excepted—than that provided. Regular meals and regular hours and habits of life were prescribed and the individuals were examined every ten days by a physician of the Public Health and Marine-Hospital Service. Systematic examinations of blood, urine and feces were made to determine the amount of boric acid excreted and the method of excretion. The mental attitude of the individuals was also carefully noted. All the young men followed their usual vocations during the experiments. Dr. Wiley states that while some of "the members of the table were made temporarily ill by the quantities of the preservative administered, it is nevertheless an interesting fact to note that at the end of the year, after the final 'after-period' had been passed, they appeared to be, and declared themselves to be, in better physical condition than when they entered on the experimental work seven months before." This probably may be explained by the self-restraint, temperance and regularity in meals and in hours for sleep and work which were insisted on during the course of the experiments. It is evident that the tendency toward a good physical state and good health produced by the regular habits of life counteracted the unfavorable tendency of any preservative ingested, so that, though the preservative might have produced injurious effects, judged by the condition of the subject, the results of the experiment might be pronounced negative.

State Boards of Registration.

COMING EXAMINATIONS.

Board of Medical Registration for Vermont, Burlington, February 7, 8 and 9. W. Scott Nay, M.D., secretary, Underhill.

Nebraska State Board of Health, State House, Lincoln, February 8-9. George H. Brash, M.D., secretary, Beatrice.

Kansas State Board of Medical Registration and Examination, Topeka, February 14-15. Secretary, G. F. Johnston, M.D., Lakin.

Connecticut Medical Examining Board, City Hall, New Haven, March 14-15. Secretary, Charles A. Tuttle, M.D., New Haven.

Massachusetts Board of Registration in Medicine, State House, Boston, March 14-15. Secretary, Edwin B. Harvey, M.D., Boston.

Maine Board of Medical Registration, City Building, Portland, March 28. Secretary, Wm. J. Maybury, M.D., Saco.

Colorado Report for 1904.—Dr. S. D. Van Meter, secretary of the Colorado State Board of Medical Examiners, reports the examinations held in Colorado during 1904. At each examination 70 questions were asked in 7 subjects, and percentage required to pass was 70. During the quarter ending March 31, 5 persons were examined, of whom 2 passed and 3 failed. Forty-six persons were licensed on diploma, 4 duplicate certificates were issued and 2 persons were refused license on diploma. During the quarter ending June 30, 4 persons were examined, of whom 1 passed and 3 failed. One hundred and eighteen persons were licensed on diploma, 2 were refused on diploma, 1 was refused on the "ten-year clause," and one examination was deferred by request. During the quarter ending September 30, 2 persons were examined, both of whom failed. One hundred and sixteen licenses were granted on diploma, 3 duplicate certificates were issued, 5 were refused on diploma, one examination was deferred by request and one deferred, "ten-year clause." During the quarter ending December 31, 86 licenses were granted on diploma, 2 duplicates were issued, 3 licenses were refused on diploma, 2 persons were examined and failed, 2 applications on diploma were deferred and 2 examinations were deferred. All applicants who are refused a license on diploma have the privilege of taking the examination.

Indian Territory Reports.—Dr. B. W. Caldwell, secretary of the Board of Medical Examiners of the Central District, reports the written examinations held at South McAlester, July and October, 1904. At both examinations the number of subjects examined in was 13; questions asked, 130; percentage required to pass, 70, and not below 60 in any subject. At the examination July 5-7 the total number examined was 18, of whom 6 passed and 12 failed. Seventeen were undergraduates. At the examination held October 4-6, 1904, 34 were examined, of whom 16 passed and 18 failed.

Dr. E. E. Owens, secretary of the Medical Examining Board, Southern District, reports the written examinations held at Ardmore July 4-5, at Chickasha October 3-4, and at Paulo Valley November 7-8, 1904. At the examination held at Ardmore the number examined was 32, all undergraduates, of whom 9 passed and 23 failed. At the examination at Chickasha the number examined was 17, all undergraduates, of whom 6 passed and 11 failed. At the examination held at Paulo Valley the number examined was 33, all undergraduates, of whom 6 passed and 27 failed.

Kentucky October Report.—Dr. J. N. McCormack, secretary of the State Board of Health of Kentucky, reports the written examination, held at Louisville, Oct. 3, 1904. The number of subjects examined in was 10; total questions asked, 100; percentage required to pass, 70, and not less than 60 in any one subject. The total number examined was 10, of whom 4 passed, 4 failed, and 2 withdrew from the examination. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
Western Reserve Med. Coll	(1901)	92
Cleveland Homeo. Med. Coll	(1904)	85
Baltimore Med. Coll	(1904)	75

Univ. of Michigan	(1903)	95.9
Baltimore Med. Coll	(1904)	87.3
McGill Univ.	(1904)	84
Tufts Coll. Med. School	(1902)	92
Eclectic Med. Coll., Milwaukee	(1895)	84.5
Hahnemann Med. Coll., Chicago	(1901)	87
Medico-Chirurgical Coll., Philadelphia	(1904)	88.5
Boston Univ. Med. School	(1904)	92
Coll. of P. and S., Baltimore	(1904)	87.3

Missouri Report for 1904.—Dr. W. F. Morrow, secretary of the Missouri State Board of Health, reports the written examinations held in Missouri during 1904. The number of questions asked at each examination was 12, and percentage required to pass, 75. At the examination held in Kansas City in April 25 persons were examined, of whom 19 passed and 6 failed. The following colleges were represented:

	Per Cent.
PASSED.	
Medico-Chirurgical Coll., Kansas City	75, 76, 81
University of Michigan	80
College of P. and S., Chicago	78, 75
Eclectic Medical University	75
Barnes Medical College	77
University Med. Coll., Kansas City	75, 78, 75, 79, 80

FAILED.	
Barnes Medical College, the grade of 52 was reached by one, 54 by one, 55 by two, 60 by three, 63 by one, 65 by one, 66 by four, 67 by two, 68 by five, 69 by four, 70 by one.	
University of Louisville	60, 54
Marion Sims-Beaumont Medical College	62, 68
Medical College of Alabama	68
College of P. and S., St. Louis	69, 69, 66, 70, 63, 40
Ohio Medical University	63
Missouri Homeopathic Medical College	60
American Medical College	64, 65

The general average attained at this examination by all representatives of Barnes Medical College who passed was 76.5; of all representatives of St. Louis University who passed, 77.3.

During the year 300 persons were registered on diploma.

New York Report for 1904.—Dr. Charles F. Wheelock, secretary of the New York State Board of Medical Examiners, reports the examinations held at Albany, Buffalo, New York and Syracuse during 1904. The total number of persons examined during the year was 793, of whom 667 passed and 126 failed. The following colleges were represented:

PASSED.

Albany Medical College had 40 representatives; Bellevue Medical College and Hospital, 49; College of P. & S., New York City, 160; Cornell University, 58; Eclectic Med. Coll. of the City of New York, 9; Long Island College Hospital, 45; New York Homeo. Medical College and Hospital, 27; New York Medical College and Hospital for Women, 9; New York University Medical College (1897), 1, 30; Syracuse Medical College, 30; University of Buffalo, 43; Yale, 9; Columbia University, 2; Georgetown University, 3; Howard University, 1; Harvard University, 6; Chicago Homeopathic Medical College, 1; College of P. & S., Chicago, 1; Northwestern University, 3; Rush Medical College, 3; Bowdoin Medical College, 1; Baltimore Medical College, 12; Baltimore University School of Medicine, 4; College of P. & S., Baltimore, 4; Johns Hopkins University, 14; University of Maryland, 1; Boston University School of Medicine, 4; Tufts Medical College, 1; Detroit College of Medicine, 2; University of Michigan, 5; University of Minnesota, 1; Omaha University, 1; Dartmouth Medical College, 1; College of P. & S., Cleveland, 2; Eclectic Medical Institute, Cincinnati, 1; Hahnemann Medical College and Hospital, Philadelphia, 6; Jefferson Medical College, 11; Medico-Chirurgical College, Philadelphia, 1; University of Pennsylvania,, 15; Western Pennsylvania Medical College, 2; Woman's Medical College, Philadelphia, 10; South Carolina Medical College, 1; University of Nashville, 2; University of Vermont, 3; University College of Medicine, Richmond, Va., 1; University of Virginia, 4; University of Vienna, 2; Laval University, Canada, 1; McGill University, 5; Ontario Medical College for Women, 2; Queens University, Kingston, Canada, 2; Trinity University, Canada, 1; University of Toronto, 5; University of Berlin, 2; University of Bonn, 1; University of Erlangen, 2; University of Munich, 2; University of Wurzburg, 1; University of Naples, 15; University of Palermo, 3; University of Rome, 2; University of Siena, 1; University of Turin, 1; University of Moscow, 2; University of St. Vladimir, 1; University of Edinburgh, 1; University of Glasgow, 1; University of Zurich, 1; American School of Medicine of the Syrian Protestant College, Beirut, Turkey, 1. License to practice medicine in the German Empire, 1.

FAILED.

Albany Medical College, 1 representative; College of P. & S., New York City, 5; Cornell University, 1; Long Island College Hospital, 1; University and Bellevue Hospital Medical College, 2; University of Buffalo, 4; Howard University, 1; College of P. & S., Chicago, 1; Illinois Medical College, 1; Keokuk Medical College, 1; Kentucky School of Medicine, 1; University of Kentucky, 1; University of Louisville, 1; Baltimore Medical College, 1; Baltimore University School of Medicine, 4; *Tufts Medical College*, 1; University of Michigan 1; Marion Sims Medical College, 1; Cleveland University of Medicine and Surgery, 1; Jefferson Medical College, 2; University of Pennsylvania, 1; University of Vermont, 3; University of Budapest, 1; University of Koenigsberg, 1; University of Athens, 1; University of Naples, 19; University of Bucharest, 2; University of Dorpat, Russia, 1; Karolinsko Medico-Chirurgical Institute, Stockholm, 1.

Vermont April and October Reports.—Dr. W. Scott, secretary of the Vermont State Board of Medical Registration, reports the written examinations held at Burlington in April and October, 1904. At each examination the number of subjects examined in was 8; total questions asked, 80; percentage required to pass, 70. At the April examination 4 persons were examined, all of whom passed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
University of Vermont (1901) 78,	(1902)	76
Amer. Med. Miss. Coll., Chicago	(1901)	81
Ohio Medical College	(1897)	77

At the October examination 8 persons were examined, all of whom passed. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
McGill University	(1902)	87
University of Vermont	(1904)	76, 70
Baltimore Med. Coll.	(1904)	86
Jefferson Med. Coll. (1903) 80,	(1904)	74
Dartmouth Med. Coll.	(1901)	84
Cornell University	(1904)	85

Washington Will Not Reciprocate.—The Washington State Board of Medical Examiners is said to have declined the request of the Illinois State Board of Health to establish reciprocity. The board is quoted as saying that it desires to treat all applicants alike, and that it will require all newcomers from whatever state to take the examination.

Association News.

Yellowstone Park and Portland Special.

As announced last week, it is proposed to run a special train to Portland, leaving Chicago June 30, stopping six days at the Yellowstone Park, and arriving at Portland on Monday morning, July 10. It is necessary to arrange with the park management some months beforehand for the dates required and for this reason it is essential to know at once *whether a sufficient number will probably go to warrant* running such a train. Will those who think they would like to go on such a train notify THE JOURNAL at once? Several letters have been received in response to the notice last week, and, as questions asked in these may be asked by others, we answer them here. One member asks if he can stop off for a month at Denver on his return; another wants to stop over at Glenwood Springs, and another at Dickenson, N. D. All these privileges can be obtained. The time limit to the tickets is fixed at 90 days from the time of starting until returning, and the railroads will be liberal in giving stop-overs on the return trip, but probably not on the outward trip. One member asks if something can not be done to avoid the trouble usually met with in getting tickets endorsed for the return trip; in other words, as the correspondent puts it, "can not there be less red tape?" Replying to this: The western roads are not given to so much "red tape" as is the case with those of the East, for it is not necessary. Possibly one or two roads will issue tickets that will have to be deposited, but the majority of the roads will not require this.

The extra expense necessary for the week at the park will be less than $50. This will include coaches, hotel expenses —in fact, everything. The number will be limited to 250.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Jan. 28, 1905:

Ford, Clyde S., asst.-surgeon, ordered to proceed from Fort Barrancas to Ormond, Florida, on public business.

Brechemin, Louis, Jr., asst.-surgeon, left Fort Baker, California, on thirty days' leave of absence.

Wythe, Stephen, contract surgeon, assigned to duty January 11 at Fort Baker, California.

Merrick, John N., contract surgeon, returned to duty at Fort Missoula, Montana, January 16 from leave of absence.

Brooks, John D., contract surgeon, returned to duty at Fort Meade, South Dakota, January 18 from leave of absence.

Whinnery, Jean C., dental surgeon, arrived at Vancouver Barracks, Washington, January 17 from leave of absence.

Ware, William H., dental surgeon, left Fort Logan, Colorado, January 21 for temporary duty at Fort Wingate, New Mexico.

Wing, Franklin F., dental surgeon, arrived at Fort Meade, South Dakota, January 20 for temporary duty.

Adair, George W., contract surgeon, granted leave of absence for two months about February 1.

Lemmon, Robert, contract surgeon, ordered from Fort Terry, New York, to Fort Wadsworth, New York, for temporary duty.

Holmes, Thomas G., contract surgeon, arrived January 24 at Fort Sheridan, Illinois, for temporary duty.

Marvin, Marion H., contract surgeon, arrived at San Francisco January 15 on one month's leave of absence from the Philippine Division.

Casaday, George H., dental surgeon, arrived at San Francisco January 15 on three months' leave of absence from the Philippine Division.

Sparrenberger, Frederick H., contract surgeon, granted leave of absence for ten days.

Nash, Francis S., contract surgeon, availed himself January 25 of leave of absence for four months.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending January 28, 1905:

Henneberger, L. G., medical inspector, detached from the *Olympia* and ordered home to wait orders.

Graove, W. B., surgeon, ordered to the Naval Hospital, Chelsea, Mass., January 30.

Wilson, G. B., surgeon, detached from the Naval Hospital, Chelsea, Mass., and ordered to the *Colorado.*

Steele, John M., surgeon, detached from the *Colorado* and ordered to the *Olympia.*

Odell, H. E., P. A. surgeon, ordered to the Naval Hospital, New York.

Taylor, J. L., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant (J. G.) from Dec. 17, 1904.

Crandall, R. P., surgeon, detached from the *New Orleans* and ordered home to wait orders.

Geiger, A. J., asst.-surgeon, detached from the *Prairie* and ordered to the Naval Station, Port Royal, S. C., for temporary duty.

Curl, H. C., P. A. surgeon, detached from duty with the Isthmian Canal Commission on the Isthmus of Panama and ordered to the *Boston.*

Guthrie, J. A., P. A. surgeon, ordered to the *Dixie,* sailing from New York on or about February 4.

Leys, J. F., P. A. surgeon, detached from the Naval Station, Guam, L. I., and ordered home to wait orders via *Solace.*

Stepp, J., asst.-surgeon, ordered to the *Constellation* and to additional duty at the Naval Training Station, Newport, R. I.

Ely, C. F., asst.-surgeon, detached from the Naval Academy and ordered to duty with the Marine Detachment on the Isthmus of Panama, sailing from New York January 31.

Baker, M. W., asst.-surgeon, detached from the *Brooklyn* and ordered to the Naval Hospital, San Juan, P. R.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Jan. 25, 1905:

Earle, B. H., asst.-surgeon, granted leave of absence for three days from Jan. 21, 1905. Granted extension of leave of absence for four days from January 25.

Foster, S. B., A. A. surgeon, granted leave of absence for twelve days from January 24.

Goodman, F. S., pharmacist, granted leave of absence for seven days from January 24.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended Jan. 27, 1905:

SMALLPOX—UNITED STATES.

Colorado: Dec. 1-31, Garfield Co., 11 cases; Lake Co., 5 cases; Larimer Co., 18 cases; Las Animas, 1 case; Weld Co., 1 case.

District of Columbia: Washington, Jan. 8-21, 4 cases.

Florida: Jacksonville, Jan. 8-14, 1 case.

Illinois: Chicago, Jan. 15-21, 18 cases, 1 death.

Louisiana: New Orleans, Jan. 15-21, 13 cases, 4 imported.

Michigan: Detroit, Jan. 15-21, 2 cases.

Missouri: St. Louis, Jan. 15-21, 24 cases, 1 death.

Tennessee: Jan. 15-21, Memphis, 10 cases, 3 imported; Nashville, 3 cases.

Wisconsin: Milwaukee: Jan. 15-21, 6 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Dec. 25-31, 5 cases.

Brazil: Pernambuco, Dec. 2-15, 85 deaths; Rio de Janeiro, Dec. 26-Jan. 1, 73 cases, 23 deaths.

France: Paris, Jan. 1-7, 10 cases, 1 death.

Great Britain: Dundee, Dec. 25-31, 3 cases; Jan. 1-7, Leeds, 4 cases; London, 1 case; Manchester, 1 case; Newcastle-on-Tyne, 4 cases; Nottingham, 1 case.

India: Karachi, Dec. 17-23, 2 cases.

Italy: Catania, Dec. 30-Jan. 5, 4 cases.

Peru: Callao, Dec. 17, 1 case from S. S. *Leo Valparaiso* via immediate ports.

Russia: Moscow, Dec. 8-14, 2 cases, 1 death; Dec. 25-31, Odessa, 1 case, 1 death; St. Petersburg, 3 cases, 3 deaths.

Straits Settlements: Singapore, Dec. 4-10, 2 deaths.

Turkey: Constantinople, Dec. 26-Jan. 1, 24 deaths; Smyrna, Nov. 20-27, 1 death.

Venezuela: Vicinity of Macuto, Jan. 1-7, 15 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, ec. 26-Jan. 1, 1 case.

Cuba: Habana, Jan. 10, 1 death from S. S. *Dora* from Laguayra and Colon.

Panama: Panama, Jan. 1-15, 5 cases, 1 death.

Venezuela: Caracas, Dec. 17-Jan. 7, 1 death; vicinity of Laguayra, Jan. 1-7, 6 deaths.

CHOLERA.

Russian Empire: Astrakan government, Nov. 23-29, 6 cases; Nov. 23-Dec. 7, Baku government, 66 cases; Erivan government, 502 cases, 238 deaths; Samara government, 32 cases; Saratov government, Nov. 23-29, 40 cases, 19 deaths; Telisavetpol government, Nov. 23-Dec. 7, 68 cases; Transcaspian territory, Serachs province, Nov. 23-Dec. 7, 47 cases, 27 deaths; Uralsk, Dec. 28, epidemic.

Turkey: General, Nov. 28-Dec. 12, 396 cases, 287 deaths.

PLAGUE.

Arabia: Dec. 25-31, Crater (hospital), 41 cases, 33 deaths; Maalla, 2 cases, 2 deaths; Hadjuff (hospital), 2 cases, 2 deaths; Alia Islands, 5 cases, 2 deaths.

Argentina: Salta State, Dec. 14, 1 case.

Brazil: Rio de Janeiro, Dec. 26-Jan. 1, 20 cases, 11 deaths

Cape Colony: Port Elizabeth, Dec. 4 10, 2 cases.

Chile: Arica, Dec. 1, present.

Formosa: Dec. 5-11, 44 cases, 35 deaths.

India: Karachi, Dec. 19-25, 54 cases, 51 deaths.

Peru: Eten, Nov. 1-Dec. 11, 24 cases; Lambayeque, Nov.-Dec 11, 13 cases; Lima, Nov. 16 Dec. 11, 14 cases; Pacasmayo, Dec. 11, present.

Society Proceedings.

NEW YORK NEUROLOGICAL SOCIETY.

Regular Meeting, held Jan. 3, 1905.

Dr. J. Arthur Booth, President pro tem., in the Chair.

Exophthalmic Goiter in a Child.

Dr. J. Arthur Booth reported the case of a girl, 13 years old, whose family history was negative. The child had suffered from measles, whooping cough and scarlet fever in infancy, but there was no history of fright, nor could any other etiologic factor be discovered. The exophthalmos was first noticed when the child was 11 years old. Six months later the enlargement of the thyroid became noticeable. The exophthalmos and thyroid enlargement were very marked, as well as the tachycardia, the pulse ranging between 120 and 140 per minute. There was also tremor, general nervousness, sweating, insomnia and occasional headaches. The interesting feature of the case was the early age at which the disease manifested itself.

Adenoma of the Pineal Gland.

Dr. Adolf Meyer presented a man who, when diving, struck the top of his head. Following this he complained of headache. He became blind in 1898, with chiasma symptoms. In 1899 he had transitory attacks of numbness on the left side of the face, except in the area of the middle branch. From that time on there was difficulty in moving the lower jaw toward the left. There was no atrophy of the masseter. In August, 1900, cerebrospinal fluid began to drip from the right nostril, with considerable relief of the general symptoms. On the few occasions when the flow stopped the patient would become sleepy and stuporous for two or three days. During May and October, 1902, the patient, who was then 22 years old, had several general convulsions. In January, 1904, death occurred in a status epilepticus. The only permanent symptoms had been weakness of the left side of the jaw, a small area of loss of pain sensation of the left lower corner of the mouth, and subjective numbness in the left side of the tongue. The gait remained normal; the knee jerks were both increased; there was *no* clonus. At the autopsy an adenoma of the pineal gland was found. It had pressed itself through the roof of the midbrain behind the posterior commissure, protruding into the third and fourth ventricle and displacing the posterior corpora quadrigemina; the adenoma had practically no sand and but slight pigmentation. The right lateral ventricle had a funnel-shaped depression in its anterior end, with a perforation through the cortex.

A Unique Case of Fracture Dislocation of the Spine.

Dr. J. Ramsay Hunt reported the case of a man, 45 years old, who gave a history of syphilis followed by suppurating bubo and numerous attacks of gonorrhea. In 1895 he fell three stories through an air-shaft. He was unconscious for a few minutes. Following the accident he complained of severe pains in the back. Both legs were partially paralyzed. After the accident an angular deformity of the spine was noted, which still exists. It is located about the level of the twelfth dorsal vertebra, and it was safe to assume that the spine had suffered a fracture—dislocation at that point—and that the spinal cord had been injured at the same time. After remaining in bed for two months the legs began to improve, and six or seven months later he was able to resume his occupation as a truck driver. One year after the injury he was suffering no pain or inconvenience, although his legs were not quite as strong as they were before the accident. He could not run as fast as formerly, owing to a slight stiffness in the knees. There was no sensory nor vesical symptoms during this period. For four years or more the patient remained in this condition. About three years ago he began to complain of sensations of numbness and cold in the feet and legs, accompanied by stiffness and weakness. On stooping he felt a numbness in the lower portion of the back, extending down the posterior aspects of the thighs and legs. During the past two years these symptoms progressed slowly and steadily, without any sudden exacerbation, and without acute pain. The left leg was weaker than the right, and it was important to note that this was true of the initial paralysis and the long period of disability during convalescence. The patient now has a well-marked kyphosis, the tip of which corresponds to the twelfth dorsal vertebra. There is a posterior bilateral band of hyperesthesia at the same level. The spinal column is fairly mobile and is not tender to pressure. There is spastic paraplegia of the lower extremities, with the spasticity and clonus more marked on the left side. Babinsky phenomenon on both sides. The skin reflexes are present and there are distinct objective sensory disturbances in the lower extremities. The man is able to stand fairly well with his eyes closed. He has considerable difficulty in urination, with occasional incontinence. His sexual power apparently was unaffected. Coarse myokymic twitchings are present in the back below the level of the lesion: also in the buttocks, thighs and legs, especially their posterior aspect, after exertion and exposure to the cold. Occasionally during the past year he has had sharp shooting pains in the course of the sciatic nerves, causing reflex movements in the legs. These are more pronounced on the left side.

Dr. Hunt's second patient was an elevator operator, 22 years old, who about two months ago fell six stories with his elevator. He was unconscious fifteen minutes after the fall. On examination it was found that he had suffered a fracture-dislocation of the spine, the deformity extending from the eleventh dorsal to the second lumbar vertebra. Six weeks later there was an oval area of anesthesia over the anterior and lateral surfaces of the right thigh. The right knee jerk was absent. The left leg was weak and spastic, with clonus. The Babinsky reflex was not elicitable on either side. A girdle sensation was felt in the lower abdominal region, especially on the right side. There was difficulty on urination.

DISCUSSION.

Dr. **Joseph Fraenkel** thought that pressure on the cord due to an osseous lesion would give rise to more severe symptoms than were present in the first case. He suggested the possibility of a post-traumatic hematomyelia.

Diffuse Cauliflower-Like Puckering of the Cortex in Arteriosclerotic Epilepsy.

Dr. **Adolf Meyer** showed a brain which showed a form of vascular affection, principally of the cortical terminals, in a syphilitic, 55 years old. There was mental deterioration, with epilepsy, for twelve years, and slowly progressing left hemiplegia during the last year of life. The small vessels of the pia in the affected regions were diffusely occluded. The lesions affected principally the occipital lobes. In the temporal and parieto-frontal regions the convolutions bordering on the sylvian fossa were intact.

DISCUSSION.

Dr. **T. P. Prout** found that one case he had observed belonged to the realm of the infantile cerebral palsies, on which epilepsy was subsequently ingrafted.

Dr. **Fraenkel** said that he had seen quite a number of cases in which epileptiform seizures developed late in life, accompanied by some mental deterioration. The diagnosis was of importance, because in a younger person such a condition would be regarded as a general paresis. These seizures could usually be differentiated from those of ordinary epilepsy by the slight focal symptoms.

Officers Elected.

The annual election resulted as follows: President, Dr. Joseph Fraenkel; vice-presidents, Drs. J. Arthur Booth and Smith Ely Jelliffe; recording secretary, Dr. J. Ramsay Hunt; treasurer, Dr. G. M. Hammond; corresponding secretary, Dr. F. K. Hallock.

AMERICAN PUBLIC HEALTH ASSOCIATION.

(Continued from page 316.)

Meeting of the Laboratory Section, held at the General Wood Laboratory, Havana, Cuba, Jan. 9, 1905.

The Chairman, Dr. V. A. Moore, Ithaca, N. Y., in the Chair.

The session was devoted largely to water and sewage. Mr. George W. Fuller of New York, chairman of the Committee on Standard Methods of Water Analysis, submitted an exhaustive report on the changes and improvements in the methods that are being used in bacteriologic tests of water. The report was ordered to be distributed to bacteriologists both in this country and in Europe.

Reports of committees on a variety of technical subjects and several papers on bacteriologic topics were read.

The Persistence of Agglutinability in Typhoid Bacilli in Water.

Prof. **Edwin O. Jordan**, Chicago, drew the following conclusions: (1) That the typhoid bacillus may be isolated without special difficulty after association with bacillus coli in tap water and sewage for from at least twelve to twenty days. (2) That some strains of bacillus typhosus retain their property of agglutinability absolutely intact under these conditions.

A Cause of the Formation of Gas in Cans of Condensed Milk.

Mr. **Charles W. Dodge**, Rochester, N. Y., stated that bacteriologic investigations of the condensed milk in cans, which were found to bulge shortly after their preparation, failed to find any micro-organisms which, either singly or in combination, would cause the fermentation of either dextrose or lactose under a variety of conditions usually favorable to such fermentations. Neither would the milk itself from such cans cause fermentation in fresh milk. It was found, however, that when dilute solutions of butyric or lactic acid, varying from 1:200 to 1:500 in distilled water, were allowed to act upon the metal of which the cans were made, a slow evolution of gas took place, its rapidity being inversely as the dilution of the acid. It is probable that in the instance cited, the gas was formed not by the bacteria directly, but by the electrolytic action between the metal of which the cans were composed and the acids generated by the growth of bacteria in the milk before the latter was condensed.

An Unusual Channel of Infection with the Shiga Bacillus.

Mr. **Dodge** stated that a laboratory worker accidentally broke a test tube containing a culture of the Shiga bacillus, and some of the fluid was carried to his eye and was probably washed down into the pharynx. Twenty-four hours later typical clinical symptoms of acute dysentery appeared, and lasted for several days. This occurrence of the accident and the infection may be merely a coincidence, but, if not, the occurrence throws light on the rapidity of infection in dysentery in man.

An Improvement in the Technic of the Indol Test.

Dr. **Joseph McFarland** and Dr. **J. Hamilton Small**, Philadelphia, devised the following improved technic for determining the presence of small quantities of indol in bouillon cultures: The culture to be tested receives an addition of one drop of chemically pure sulphuric acid for each cubic centimeter of fluid, this being well shaken. In case the microorganisms produce both indol and nitrites, the red color now makes its appearance. When, however, the organisms produce no nitrites, the usual dilute solution of potassium nitrite is allowed to trickle slowly down the side of the tube and form a layer on the surface of the fluid it already contains. The red color of the nitroso-indol now makes its appearance at the line of contact of the two fluids. Tests on artificially prepared solutions of indol of upwards of 1:750,000 gave positive results. The authors stated that this improved method is applicable for showing the presence of indol in melted gelatin cultures. After the gelatin has hardened, the color ring is fixed for a period of from twelve to twenty-four hours, when the color becomes diffuse.

Mr. Freeland Howe, Jr., detailed some results in the use of different kinds of nutrient media with different periods of incubation, and gave the results of observations on the water of the Susquehanna river at Harrisburg, Pa.

Dr. F. C. Harrison, Guelph, Ont., gave the results of an examination of the water supply of Frederickton, N. B. He discussed briefly the sewerage and water supply systems of that city.

Mr. Earl B. Phelps, Boston, contributed some notes on the determination of the organic nitrogen in sewage by the Kjeldahl process.

Election of Officers of the Laboratory Section.

Chairman, Dr. Wm. H. Park, New York; vice-chairman, Mr. H. W. Clark, Boston; secretary, Dr. John S. Fulton, Baltimore; recorder. Dr. H. D. Pease, Albany.

Travel Notes.

FOUR THOUSAND MILES THROUGH INDIA BY RAIL IN MIDSUMMER.

NICHOLAS SENN, M.D.,
CHICAGO.

(Concluded from page 320.)

TAJ MAHAL.

The Royal Tomb, Taj Mahal, at Agra, is the most costly and the most beautiful mausoleum in the world. It was built by Emperor Shahjehan Jeman for his wife, Bagum. It was commenced in 1629 and completed in 1648. It is the most significant landmark of the power, glory and wealth of Turkish rule in India, and Agra to-day is a very important stronghold of Mohammedanism in India, as one-half of its population of 150,000 are Mussulmen. How so much money could be spent in memory of even a beloved empress surpasses all understanding. The entrance to the building which contains the tomb is a specimen of exquisite architectural art. From the entrance a pathway, paved with the purest white marble, leads to the main building, lined by columns of the same material and on each side a row of arbor vitæ, the tree so constantly found in Mohammedan cemeteries.

> "Thou must leave thy lands, house and beloved wife, nor shall any of those trees follow thee, their short-lived master, except the hated cypress."—Horatius.

The passage between pools and fountains and lovely flowers and shrubbery up to the steps of the magnificent marble building characterized by symmetry and beauty in which the precious ashes of the empress have found their last resting place, is unequaled in the world for its exquisite architectural design. The real tomb is in the basement, side by side with that of her husband. The emperor had planned a separate mausoleum for himself of black marble on the opposite side of the Jumna. The building was commenced on a large scale, but death overcame him prematurely and he now shares the ample space of the mausoleum which was intended exclusively for the last resting place of his wife.

DELHI.

Delhi is unquestionably the most interesting city in India. I mean by this not Delhi of to-day with its 300,000 inhabitants, but the Delhi of long, long ago with its ruins of palaces, temples and tombs spreading over a length of ten miles by a breadth averaging a little less than six. In this area are comprised the traditional "seven castles and fifty-two gates" spoken of as far back as 1611 by the merchant Finch. This entire area is literally strewn with remnants of the glory of the Delhi of the past. The palace of the Moguls within the fortress of Delhi is a magnificent specimen of Indian architecture, a combination of symmetry and beauty of design. The road from Delhi to the old town of Qutab, twelve miles distant, passes over and on each side as far as the eye can reach ruins of former wealth and power come into view. In this great stretch of country millions and millions of people have lived and struggled centuries ago when Delhi was the Rome of India. The most conspicuous landmark of ancient history here is the minaret Qutab, 238 feet high, sloping from the foot. Although struck twice by lightning, it remains in a good condition of preservation, a strong reminder of the former powerful Mohammedan reign. The remaining historical ruins of Old Delhi in the immediate neighborhood of the colossal minaret are the mosque and tombs of Altamsh and Adham Khan, noted for their simplicity and architectural beauty. I met here a guard, a native, an old veteran who served under Lord Roberts during the Cabul war. He was proud of the decoration he wore on his breast, but, like all other guards in charge of public institutions, his right hand was converted into a big shallow cup for the reception of a handsome tip when I was ready to say goodbye. I took breakfast at the Rest House, kept by a Turk. In view of the nationality of the host, I expected to enjoy a good cup of coffee. The stuff that was served as coffee was absolutely beyond criticism. I asked to be shown the coffee used in its preparation. I was handed a package wrapped in a yellow paper and containing a pitch black pasty mass. It bore the following delusive label: "Symington's French coffee, prepared as in Paris and blended with the finest chicory." Judging from the taste and smell of the black infusion I became satisfied that it was made from poor chicory without even a blending of coffee. During our return trip the mercury in the thermometer went up to 126 F.

The Royal Palace in Delhi, within the great fort on the bank of the Jumna river, is in a good state of preservation and an imposing example of ancient Indian architecture. The great temples, old and new, scattered all over India, remind one very forcibly of:

> "No nation is so barbarous, no one so savage, whose mind is not imbued with some idea of the gods. Many entertain foolish ideas respecting them, yet all think that there is some divine power and nature."—Cicero.

Their grandeur and beauty suggest:

> "There's nothing ill can dwell in such a temple;
> if the ill-spirit have so fair a house, good things
> will strive to dwell within it."—Shakespeare.

A PARSEE WOMAN DOCTOR.

On my arrival at Jaipur the proprietor of the Rustem Family Hotel informed me that the only other guest in the house was a very distinguished Parsee woman doctor. He said that her reputation has spread all over India and that she was well known in the medical circles of Europe. Naturally these statements excited my interest. I was anxious to get some particulars of the medical and surgical work of women in India and to obtain additional information regarding the status of gynecology and obstetrics in that country. At dinner she occupied a seat opposite me at the table. She was a woman well beyond blooming youth with a yellow, freckled face, coal black eyes and hair. She was dressed in flowing silk of different colors, with ruby red in the lead, and displayed a profusion of what appeared to me cheap jewelry. She displayed a nervous disposition. She brought a new book with her, which she seemed not to read, but glance over in a very nervous manner during and between courses. The attention paid to her by the waiters proved to me that she was no stranger in the house. The proprietor of the house was, like her, a Parsee, a fire worshiper. From the appearance and behavior of the woman I became satisfied that I had a colleague to deal with from whom I had little to expect in the way of professional courtesy, and yet a possible opportunity to increase my stock of medical and surgical knowledge from such a rare source was too tempting not to make an effort to obtain it. With many misgivings I made the attempt very cautiously. Nothing but an occasional timid, lightning glance was exchanged during dinner. After dinner I sent my servant to her room with my card. He returned a few moments later with the discouraging information, "The lady is too tired." Disappointed as I was in receiving this not entirely unexpected news, I had the satisfaction of knowing that I had done what I deemed my duty. The next day I was "too tired," because in the meantime I had ascertained that the much famed Parsee woman doctor knew more about fire worship than medicine. A strict armed neutrality was maintained on both sides during the remaining time we were obliged to live under the same roof and to eat at the same table. A red cloth-bound book was her invariable silent table companion. It was not a medical book. It must have been either a novel or some occult treatise on fire worship. Of the meeting with this woman I can not say, as of all other members of the medical profession that I had the pleasure of meeting on my long journey:

> "Friendship, mysterious cement of the soul.
> Sweet'ner of life and solder of society."—Blair.

A SICK ELEPHANT.

From Jaipur I made a trip to the old capital city, Amer, its palace and wonderful mountain fortifications, eight miles distant from the present seat of government of Jaipur state. The old city is enclosed by mountain ridges 1,500 to 2,000 feet high, all strongly fortified. The city is now in ruins and nearly deserted. The palace and fortifications are in good repair. It was arranged the evening before that I should go by carriage as far as the base of the mountain, where an elephant would be in waiting, who would take me over the mountain ridge to the old city, and from there up the steep incline to the palace and fortification. When morning came I was informed that the elephant was sick and that a bullock cart would be sent instead. In making inquiry regarding the elephant's sickness I ascertained that the huge beast, quite old, had for several years been suffering at intervals from acute attacks of illness. He would fall down suddenly, with great pain. These attacks would last from three to four hours, when he would recover and remain in apparently good health until the next attack. I am quite confident that this giant beast is the subject of gallstone of enormous size and that it is only a question of a short time before he will die from a complicating suppurative inflammation of the bile ducts. When we came to the foot of the mountain the bull cart was conspicuous for its absence. I was determined to see the old city, palace and fortification, and there was no other alternative left but to make the trip of two miles and the climb of 1,500 feet on foot in a temperature of 132 F. as registered by my thermometer. It is needless to say that when I reached the palace my clothes were not only wet through and through, but my feet and socks were soaked in sweat that ran down the legs in streams.

After seeing the sights the belated bullock cart arrived, and on it I made the return trip. The cart was a first-class one, but what a vehicle! I first tried to ride à la native by doubling myself up in monkey style. As the springless rough cart jumped over stones, into and out of ruts, this position soon became unendurable. If it had not been for my inborn pride to surmount hardships I would gladly have jumped out, paid the owner and his old wife, who accompanied us and who helped her spouse in keeping the bullocks in motion for their trouble, and returned as I came, on foot. As it was, I rendered my position endurable by sitting crosswise in the cart with the numb legs hanging over one of the immense wooden wheels. I made up my mind at the time that as long as I remained in India I would ride on anything else but a bullock cart. It was my first and last experience with this rude antiquated native vehicle.

A CROCODILE TANK.

In the rear of the palace of the mahajarah of Jaipur is a tank covering several acres and containing a greenish turbid water covered for the most part with the scum of algae. It is inhabited by crocodiles and turtles. Stone steps lead down from the palace to the edge of the water. On the advice of the guide we had brought with us from a neighboring butcher-shop delicacies with which to feed the crocodiles. As soon as we reached the edge of the tank a palace guard commenced to make a barking noise and in a few minutes something appeared on the surface of the water which looked like a black log about fifteen feet long. The scuttling motion of the smaller end of the log showed that it was a crocodile on the way to accept the proffered invitation for tiffin. Slowly, lazily, the monster approached, and as it came up to the steps an immense moss-covered head with small slit-like eyes came above the surface of the water with the cavernous mouth wide open, displaying two rows of sawlike teeth. With unerring aim he caught the fragments of meat, which at once disappeared from the tongueless mouth. In less than ten minutes four other crocodiles and a large turtle were our guests. One of the largest of the beasts, a monster at least twenty feet long, took the liberty to climb the steps in order, I presume, to cultivate a closer acquaintance with us. A few blows with a club administered over the skull by the guard brought him to a standstill, and with a tremendous splash he returned to his proper element and disappeared from sight.

A BELATED BRIDAL CEREMONY.

One Sunday afternoon, while driving through one of the principal streets of Jaipur, I heard the ear-killing strains of native musicians. I brought the carriage to a standstill and a procession soon made its appearance, headed by the band. It was made up exclusively of women, from four to six abreast, each of them carrying on the head a basket containing sweets and other small presents. It was explained to me that this procession was in honor of a woman who in four weeks would make her first addition to the census of the city. It was not difficult to locate the bride of eight months in the first row of the procession. The husband was not there. He was at home awaiting the presents from his father-in-law, conveyed to him by the members of the procession. Later in the day I saw another procession on a larger scale announcing to the public a similar event. This custom, which to me appeared a praiseworthy one, is generally observed, and if the census taker of Jaipur keeps his ears ready and his eyes open, he has no difficulty in keeping track of the increase of the population.

FEAST OF THE NEW MOON.

As I was elbowing my way through the crowded streets of Jaipur, on Sunday evening, soon after sundown, I saw thousands of eyes looking in the direction in which the scorching sun had so recently disappeared. I was told that it was the feast of the new moon. It was a long time before I could see the goddess that was the object of worship that evening. I finally could make out the faintest outlines of a pale little sickle—it was the new moon. A great procession formed in honor of the event, headed by a native band, a gaudily caparisoned elephant, a squad of police, and followed by a company of native soldiers. The moon is held in high esteem as a goddess by both Brahmins and Buddhists, and the new moon is always greeted with joy and heralded by a religious procession.

A FAITHFUL ROMAN CATHOLIC PRIEST.

At Abu Road a gentleman, plainly dressed, with full beard well peppered with gray, entered my compartment and at once entered into a lively conversation. He spoke English as it is spoken in England and I took him for an Englishman, probably an employe in the civil service. In removing his cheap gray helmet I noticed that the top of his head as large as the palm of the hand was shaved. There was now no doubt in my mind concerning the vocation of my new companion. He informed me that he was a Roman Catholic priest, and furthermore, that he was a native of Switzerland, had been in India since he entered the priesthood 26 years ago, and that for eight years he had served as chaplain in the army, and was now on his way to visit a detachment of troops at Ahemabad. It further developed that our birthplaces in Switzerland were not far apart. It was a strange coincidence that I should find here in the wilds of India a countryman whose cradle was so near to mine. Rev. B. Jost, S.J.R.C., chaplain, has spent his whole professional life in India as a missionary and chaplain. He has never taken a vacation. He has seen the horrors of famine and the ravages of cholera, and other devastating epidemic diseases and has but once left his post when, stricken by fever and dysentery, his physician insisted on his being taken to Bombay to save his life. He was tenderly nursed by his brother priests, who for a long time had no hope that he would recover. His vigorous Helvetian constitution and determined will triumphed. He recovered and at once returned to his station. During the last famine, which extended over four years, he spent the money sent to him by friends in buying food, and dealt out rice and peas with his own hands during the hottest months of the year and was the means of saving 600 lives from starvation. He has exposed himself to all kinds of privations and dangers. In one day he dispatched four of the most deadly vipers in his yard and bungalow. All honor to such a brave, faithful servant of the Roman Catholic church.

> "Calamity is an opportunity to show one's virtue."—Seneca.
>
> "Fire tries gold, misery tries brave men."—Ibid.

ELEPHANTA CAVES.

The most interesting place I visited during my stay at Bombay was the Cave Temple in Elephanta Island, one hour and a half by sailboat from the city. The elephants' island is about three miles in circumference, is forest-clad and interlaced with a very pretty creeper, which blossoms more than half of the year. The caves, which in reality are a large Brahmin cave temple, are, according to Hindu tradition, 4,000 years old. There are five caves, but the one usually visited is the Great Cave, which is located about 250 feet above the level of the sea. It is hewn out of solid, hard rock. It is about 130 feet long and of the same width, and 17 feet high. At present it is only used as a place of worship on occasions of Shiva festivals, and in the middle of February a religious fair is held here. The sculptures which ornament the walls are cut out of the rock as well as the columns which support the stone ceiling. All of them show the ravages of time. Some of the columns are destroyed whole or in part, and large pieces have been split off from many of the mural figures.

> "In short, do you not see stones even yield to the power of time; lofty towers fall to decay and rocks molder away? Temples and statues of the gods go to ruin, nor can the gods themselves prolong their dates or give reprieve from fate."—Lucretius.

Of the nine allegorical figures illustrating the Brahmin cult I will only briefly describe the central one which represents Brahma, the creator; that on the right is Vishnu, the preserver, and Shiva, the destroyer. on the left. This is the most elaborate and striking of the sculptures. Brahma's face is expressive of peace, kindness and reflection. If the artist of this exquisite work of art made any mistake it was in sparing stone in forming the thick everted lips. Brahma holds a lotus flower in his left hand; Shiva holds the deadly serpent, the cobra. The significance of the pomegranate is creation; that of the lotus flower preservation, and that of the ugly snake in threatening attitude, destruction. The figures on each side are supposed to be doorkeepers, each attended by a dwarf. The figures of this masterpiece of the sculptor's art of 4,000 years ago are well preserved and a study of them will satisfy any observer of the great skill of Indian artists of that remote period. In front of the open temple is a small tank, in the shallow water of which a number of pigmy frogs enjoyed their childish frolic. No one can visit this venerable cave temple without becoming deeply impressed with the art of India long before the infant Moses was rescued from the crocodile infested Nile and long before Romulus was weaned from the breast of his ferocious wet nurse.

A GREWSOME CHARNEL HOUSE.

The Parsee people who came from Persia to India centuries ago, and of whom there are now about 100,000 in Bombay, are fire worshipers, and neither burn nor cremate their dead. They dispose of their dead by exposing them in a place where vultures can devour them in peace and safety. The Tower of Silence is the place where the hundreds of vultures are fed by the bodies of the dead Parsee. These towers, five in number, and the Fire Temple, the place of Parsee worship, are located on Malabar Hill, in elevated beautiful grounds which have an area of over 75,000 square yards. These grounds are surrounded by a high stone wall and strangers are not admitted without a special permit. The Towers of Silence, the largest of which measures 276 feet in circumference, are all surrounded by high walls, about 25 feet in height, and have an opening on the ground level, through which the dead bodies are carried. The corpse bearers are the only persons allowed to enter the towers. The bodies of the deceased are laid in grooves around the well, which is in the center of the tower. The corpses of children are laid in the center circle, those of the women in the second and those of the men in the outer ring. The bodies exposed in this manner are in a short time stripped of the flesh by the hundreds of vultures that are always in waiting for the arrival of the dead, and then the bones are thrown into the well, where they are allowed to decompose. On the day I visited this grewsome spot I saw hundreds of these bird cannibals perched in neighboring trees and on top of the towers, their gizzards evidently gorged with human flesh, motionless, hanging heads, drooping eyelids, sleeping, dreaming of the next feast on the first corpse of the community of fire worshipers. Should the interval between the dead marches be a long one, these cannibals of the air will be very hungry, a lively struggle will ensue for a share of the body exposed, fingers, toes and other parts of the body will be torn off and carried away to some quiet retreat, to be devoured at leisure. It is in this way that parts of the skeletons of the Parsee dead find their way into the dooryards, streets, gardens and on to house tops, grewsome relics of a grewsome practice of disposing of the dead.

CONCLUSION.

In conclusion, it is to me a source of great pleasure to extend my sincerest thanks to the members of our noble profession whom I had the opportunity to meet and to whom I am deeply indebted for their uniform courtesy and charming hospitality.

On Board S. S. Kronprinz Wilhelm,
Harbor of New York, Oct. 11, 1904.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Enuresis in Children.

After enumerating and excluding the many possible causes of enuresis and assuming it to be a neurosis, Ullman, in New York Med. Jour., states that an atony of the muscle, an insufficient innervation and hypersensitiveness of the lumbar centers exist and recommends the following outline of treatment:

HYGIENIC.

The child should have an outdoor life and should eat nutritious food at regular intervals. Stimulants, such as coffee and tea, should be interdicted and no liquids should be drunk before retiring. The sleeping room should be well ventilated and the bed should be hard. The child should be taken up once in the night to empty the bladder.

PSYCHICAL AND SUGGESTIVE.

Suggestion in combination with other treatment produces good results in these cases, according to the author. Corporal punishment should not be allowed, as the child's sleep becomes disturbed and he becomes fretful and goes to bed in fear. On the other hand, it is more reasonable to reward the child for not wetting the bed rather than to punish him when he does so. It is just as reasonable to inflict punishment for the involuntary movements of chorea or athetosis as in cases of enuresis. In order to obtain the best results the confidence of the patient must be obtained.

PHYSICAL AND MECHANICAL.

In this connection the different authors recommend massage, sponging with alcohol, friction and sea bathing. Kellogg recommends that the patient be placed in a sitz bath, his feet in a hot foot bath, the head cooled by a wet towel and vigorous friction applied to the hips, back and thighs and continued for three or four minutes at a temperature of 65 degrees F.

Ullman also outlines the method of Csellag, which consists of the following movements:

1. The rectum is freed of feces and massage is applied by means of the index finger to the sphincter vesicæ, the child lying in the lithotomy position. This should be continued by sphincter vesicæ for from half to one minute.
2. A deep circular massage is applied over the hypogastric region for two or three minutes.
3. The patient is placed in the dorsal position, with the knees tightly drawn together, and resists the attempt to separate them and then resists adduction. The same resistance of adduction and abduction is also carried out from the thighs. These movements should occupy two minutes.
4. The patient is then directed to stand against the wall or door and cross and recross one thigh over the other for a period of five minutes.
5. He is then taken across the knee and the lumbar and sacral regions are sharply tapped, producing rapid vibrations.

The galvanic current is recommended by some authorities; the negative electrode is placed over the lower dorsal region and the positive is applied to the perineum by means of a small button electrode, using a weak current for a period of eight minutes daily.

MEDICINAL.

The medicinal treatment of enuresis given alone produces negative results. The fluid extract of rhus aromatica, given in five-drop doses three times a day to infants, and increasing the dose with the age to fifteen drops three times daily. Atropin, one grain to two ounces of water, and giving five drops of this solution at 4, 7 and 10 p. m., is recommended. This preparation, according to the author, in connection with the movements mentioned, will produce good results.

A frequent cause of enuresis, according to Holt, is preputial adhesions, which should be broken up and the smegma removed. If phimosis is present it should be relieved by stretching or by circumcision. A narrow meatus should be cut to the proper dimensions. If stone in the bladder is suspected and if micturition is accompanied by straining and painful spasm, the bladder should be sounded. Pinworms in the rectum should be treated by salt water injections or other preparations. The reaction of the urine should be ascertained and if uric acid crystals are found, alkalies are indicated with a great deal of water.

The child should not be overtaxed at school and all excitement must be avoided. The diet must be carefully regulated and coffee, tea and beer prohibited. Sweets and all highly seasoned foods must be eliminated from the diet. Dr. Holt's experience is that the exclusion of meat is not indicated. The amount of water should not be limited except, perhaps, late in the afternoon a less quantity should be taken. The best diet is composed of milk, vegetables, fruits, meat and cereals. Punishment is of no value, and in most cases is harmful. The moral treatment is recommended, appealing to the child's pride and endeavoring to strengthen his will. When the incontinence is only at night the child should be instructed to retain the urine as long as possible during the day in order to accustom the bladder to a greater amount of water. Any anemia, malnutrition, indigestion and constipation must be corrected. Adenoids must be looked for and removed, as they tend to increase the irritability of the nervous system.

As to medicinal agents Dr. Holt ranks belladonna first; it is given in full doses until the physiologic effects are produced and it must be continued, in most cases, for many months. Atropin may be used instead of belladonna and is, perhaps, preferable, as its strength is more uniform. The proper dose should be obtained, as shown by its physiologic effects and continued for at least two months, and then gradually decreased if the incontinence has ceased. Strychnin may be added to the treatment in cases not yielding to the atropin alone. This preparation is especially useful where there is diurnal as well as nocturnal incontinence, for in such cases there is generally a lack of tone to the sphincter and also an increased irritability of the mucous membrane of the bladder. This latter preparation may be given in initial doses of grain 1/100 (.0006) twice daily, gradually increased to grain 1/50 (.0012) three times a day.

Other measures may be resorted to, such as elevating the foot of the bed at night, to keep the urine away from the neck of the bladder, and efforts should be made to keep the child from sleeping on his back. If a contracted bladder is suspected, as shown by a history of incontinence for several years and inability to retain more than one or two ounces at a time, the bladder should be distended daily to its normal capacity by means of warm water.

Sore Throat.

The term sore throat, according to Dr. Leonard Williams in the *Clinical Jour.*, London, includes the several varieties of bacterial involvement, such as the streptococcus and diphtheria bacillus. Aside from the bacterial examination, the knee jerks should be tested and the urine examined for albumin when diphtheria is suspected, as these phenomena, as a rule, occur early in the disease. If diphtheria is found to be the cause of the sore throat and antitoxin can not be obtained early, the author recommends that isolation be carried out in the usual way and a mixture containing the biniodid of mercury be given. This preparation is insoluble in water alone, but is freely soluble in an excess of potassium iodid. The following combination is recommended:

℞.	Hydrarg. perchlor	gr. i		06
	Potassii iodidi	gr. xx	1	30
	Glycerini	ʒii	8	
	Aquæ q. s. ad	℥viii	240	

M. Sig.: One teaspoonful to a tablespoonful three or four times daily.

In the foregoing mixture a double decomposition occurs, forming the biniodid of mercury about grain 1/8 (.008) to the ounce. The glycerin is added in order to increase the tendency to adhere to the fauces and thus increase its local effects. As a bactericide the biniodid is said to be four times as powerful as the perchlorid, and it does not have the tendency to throw down an inert albuminate when coming in contact with the tissues.

The author is emphatic in his statement that this preparation of mercury, excepting, of course, antitoxin, is a more effective foe of the Klebs-Loeffler bacillus than any other drug or inhalation or local application which has ever been used. In all forms of sore throat the heart should be frequently examined as in rheumatism and chorea.

In an ordinary case of sore throat the first thing to be observed is the degree of temperature. The tincture of aconite in one drop (.06) doses every hour, when the effect can be watched, is very valuable in reducing the fever and in making the patient more comfortable. The author prefers to administer aconite with other preparations which have also a local effect. In cases where a rheumatic origin is suspected, guaiac is recommended as a fair substitute for the salicylates, combined as follows:

℞.	Potassii chloratis	gr. x		65
	Tinct. aconiti	m. v		30
	Tinct. guaiaci ammon	ʒi	4	
	Mucil. acaciæ	m. xx	1	30
	Aquæ q. s. ad	℥i	30	

M. .Sig.: This amount to be taken at one dose and repeated every four hours.

As soon as the temperature has fallen the aconite should be discontinued, but the other ingredients kept up for a time. When rheumatism and diphtheria are absent the author recommends rather a complicated combination, including the tincture of iron, which is of value in such cases:

℞.	Tinct. aconiti	m. ii-v		12-.30
	Potass. chloratis	gr. x		65
	Liq. ferri perchlor	m. xx	1	30
	Liq. hydrarg. perchlor	m. x		65
	Glycerini	ʒii	8	
	Aq. chloroformi	℥ss	15	

M. Sig.: At one dose and repeated every four hours. Or half the quantity every two hours.

[The dose of potassium chlorate is larger than is usually recommended.]

The mercurial preparation is added to combat any cocci which escape the iron preparation. And the glycerin is added to prolong its local effect in the fauces.

Sciatica.

The disturbances in the sciatic nerve resulting in the symptom complex recognized clinically as sciatica is due to a variety of influences, traumatic, infectious, toxic and circulatory, and, accordingly, no one method of treatment can be expected to be serviceable in all cases. For this reason, when the causative factors can not be directly attacked and removed, the affection is likely to be long continued and attended with exacerbations. The large number of remedies employed is an index of the difficulties with which the treatment of the condition is surrounded. Excellent results have been obtained in a considerable number of instances from the injection of various substances about the nerve at its point of exit from the pelvis and in its course. Dr. J. Lange, in the *Münchener med. Woch.*, reports the successful employment of a modification of the method of infiltration-anesthesia introduced by Schleich. He first produces a wheal over the sciatic foramen and then introduces deeply through a long needle from 70 to 100 c.c. of a solution containing 1 part of eucain-B. and 8 parts of sodium chlorid in 1,000 parts of water. There is no pain as the needle passes through the skin and muscle, but the patient winces when the nerve or its sheath is reached. There is almost immediate relief, although some tenderness and induration persist for a day or two. Sometimes it becomes necessary to repeat the injection in the course of a few days. The treatment should naturally be reserved until other means have proved inefficacious; nor is it to be expected that it should be successful in all cases. The good permanent results observed in the cases treated by the means described are attributed not to the small amount of eucain introduced, but rather to the mechanical effects of the isotonic solution employed.

De Blois of Trois-Rivières lauds the fine results he has obtained with electricity in old, rebellious cases of sciatica. He uses the Morton current combined with static douches and sparks. In one of the six cases he describes in detail in the *Bulletin Méd. de Quebec*, the sciatica had persisted for two years, rebellious to the salicylates, massage and other measures, including other forms of electricity. During three months and a half he gave static douches for twenty minutes every second day, with sparks on the spine and over the affected nerves. Alternate days the Morton current was applied and superheated air locally for thirty minutes three times a week. By the second week the patient was so much improved that he could return to business, and by the end of three months and a half he was permanently cured. No recurrence has been observed in any case thus treated. His experience with the Morton induced static current has been equally favorable in neuralgia, lumbago and all kinds of muscular pains, as he relates in detail.

Medicolegal.

Contract with Health Officer to Care for Smallpox Cases.—The Supreme Court of Iowa says, in the case of Dewitt vs. Mills County, that, in December, 1901, an epidemic of smallpox broke out in the city of Glenwood, and the plaintiff was employed to render all necessary medical services to those afflicted with the disease. In an action brought to recover for such services, that part of the answer alleging that at the time of entering into the contract the plaintiff was a member of the city council of Glenwood, and also health officer of its board of health, was stricken out, on motion, as being immaterial and irrelevant. The ruling was correct. Glenwood is a city under special charter, and the board of health consisted of five members designated by the mayor. The plaintiff was not one of these, and there is nothing in the statutes prohibiting him, in an emergency, from being employed by the board of health at an agreed compensation. Section 1026, Code. This was not subject to the approval of the council, and the contract was not invalidated by Section 943 of the Code, prohibiting any member of the council from becoming "interested directly or indirectly in any contract for work or service to be performed for the corporation." The corporation referred to is the city, and, as the service was not to be rendered for it, but at the expense of the county, the statute does not apply.

Pregnancy and Miscarriage Not to Be Anticipated.—The Court of Appeals of Colorado says, in town of Florence vs. Snook, a personal injury case brought against the town, that pregnancy is not a usual and natural condition of women. It is an unusual and peculiar condition or state of health. A miscarriage can only result from an injury to a woman when in this unusual and peculiar condition, and, when relied on to increase the damages claimed, must be pleaded. The only authority cited opposed to the above doctrine was Tobin vs. Fairport, N. Y., 12 Supp. 224—a ruling by the judge of the Circuit Court of Monroe County, New York, on a motion for a new trial. But the Court of Appeals of Colorado says that the reasoning of the judge in the case cited was not at all convincing, and it is not inclined to be controlled thereby. No authority other than the Tobin case, it says, was cited, and an exhaustive examination failed to discover one in which the point under consideration has been expressly ruled. However, in a great many of the cases examined it appeared that the pregnancy of the plaintiff and the resultant miscarriage were alleged in the complaint, which would indicate that such allegation was deemed necessary.

Treatment of Dislocation of the Clavicle.—The Supreme Court of Iowa says, in the malpractice case of Tomer vs. Aiken and another, that the plaintiff suffered a dislocation of the clavicle from the acromion process. Dr. Aiken was called, but refused to treat the patient unless another physician were present. The family explained that they had been unable to get any one else, and the physician then sent for Dr. Trout to assist him. On his arrival Tomer was examined, and, according to four witnesses, the physicians announced that the collar-bone had been fractured or broken. Two of these were uncertain of the language used, while the physicians testified they concluded that it was a dislocation only, and Dr. Aiken that he had explained to Tomer that the collar-bone was broken away from the scapula; and in this he was confirmed by another witness. While the physician, in trying to explain the injury so as to be within the comprehension of those not familiar with medical terms, may have been misunderstood, yet, the court says, the evidence was such as to leave the question as to whether the case was properly diagnosed an open one for the jury's determination. If it be conceded, however, that the physicians declared it a case of fracture of the clavicle rather than dislocation, they were not liable unless improper treatment followed. No one claimed on the trial that the clavicle had been fractured, nor was there any evidence that the dressing applied was adapted peculiarly to remedying that defect. If suitable at all, it was as appropriate to the reduction of a dislocation. In these circumstances there was no occasion to submit the issue raised in the first count of the petition that, because of a mistake in the diagnosis, the plaintiff had been treated for a fracture rather than a dislocation, to the jury. If the treatment was such as reasonable skill and care exacted for the cure of a dislocated clavicle, the defendants were not liable, regardless of what their diagnosis may have been; otherwise they were. Was the dressing such as should have been used in reducing the dislocation and securing rearticulation? Ordinarily, little difficulty is experienced in reducing the dislocation. The trouble is to retain the bones in a position so that articulation will be effected. The narrow extremity of the articulating surface, the movability of the shoulder, the contraction of the muscles, and the possibility of ligaments falling between render the result somewhat experimental. In applying the dressing difficulty is experienced in securing a purchase which will hold the bones on the same level. A physician on whose testimony as an expert the plaintiff relied, freely admitted that "there is no assurance under any form of treatment that the bone is going to stay there," and testified further that "the results are not always satisfactory under any form of treatment, but the majority of them get well. Complete is more difficult than incomplete dislocation, but is sometimes successful. The majority are successful under modern methods." In this view all the physicians concurred. Failure to effect a cure under such circumstances, the court continues, furnishes no evidence of want of care or skill. The patient suffered considerable pain, but this, as the evidence showed, may have been incident to the character of the injury. The accident occurred on Wednesday, and Dr. Aiken did not call again until the Sunday following, and not again until a week from that day. If the injury required no attention during the intervals, he was not chargeable for neglect, if any there was; and in determining whether he was negligent, another physician's custom in his own practice could not be accepted as the criterion. That must necessarily depend on the custom or practice in similar localities in the treatment of such injuries. But if Dr. Aiken was negligent in not attending his patient as frequently as he should, this was no fault of Dr. Trout. He had nothing to do with the case after the first dressing was applied, and was in no way responsible for anything that happened thereafter, unless resulting from some defect therein; and the jury should have been so instructed. The dressing was put on at about 3 o'clock in the afternoon, and in the evening the plaintiff's attendant tried to reach Dr. Aiken, but could not do so, by telephone. She then telephoned for Dr. Trout, who responded that he could not come, and, on a second inquiry, that he was in bed and could not come. Without other showing save that Tomer was suffering much pain, which is usual in such cases, a physician was asked, in substance, whether under the circumstances disclosed, it would be proper treatment for a doctor to refuse to attend a patient. There was no claim that any relapse or evil consequences resulted. Another physician, in fact, called and thinned the wad under the arm. The employment of Dr. Trout had terminated at the completion of the dressing. He had the perfect right to refuse to be employed further, especially while the attending physician was still in charge of the case. Moreover, he was not advised that Dr. Aiken, who was at home, but temporarily without telephone connection, could not be found. As the case stood then, Dr. Aiken knew nothing of the plaintiff's wish that he call, and did not learn of it till Sunday, the day he had set for his next visit; and Dr. Trout was not in the plaintiff's employment, and was under no legal obligation to attend him. Manifestly, then, the objection to the question should have been sustained. That the answer, consisting of a somewhat extended discourse on medical ethics, was prejudicial, the court entertains no doubt. The court concludes that if the defendants were negligent, it was in the method of dressing adopted. But there was a difference of expert opinion on the subject, and the court decides nothing with reference thereto, except that the value of expert opinion can not be determined by counting noses, and, even though six physicians took one view and one the other, the issue was for the jury to decide. A judgment for the plaintiff is reversed.

1. Psychiatry and Other Sciences.—Dana discusses the relations of psychiatry to economics, psychology, physics, psychotherapy, neurology and internal medicine, pathology and physiologic chemistry, criminology, forensic or legal medicine, and anthropology, and indicates the lines along which work can be carried with mutual help to all, but to the special advancement of a sounder knowledge of the pathology of the mind, the capstone of all the medical sciences.

3. Erotomania.—Corning defines erotomania as an enormous erethism of the psychic centers, with its morbid psychosexual ideation, co-existing with depression of the mechanism of normal sexual animality, and constant inhibition of desire. Like other monomanias, erotomania has its root in degeneracy. Consequently, the various physical and mental stigmata may be found in the erotomaniac. Among the more striking physical stigmata are deformities of various kinds, such as malformations or incomplete development, or enormous overgrowth. Hence, malformation of the external ear, asymmetry of the face, unequal development of the two halves of the cranium, harelip, strabismus, irregularity in the shape and position of the teeth, flat, ridged or pointed palate; enormous development of the jaw, observed in criminals, and webbed or supernumerary fingers. Prominent among the mental stigmata are lack of mental equilibrium, hyperemotionality, inordinate impulsiveness, powers of imagination so extraordinary as to attain the dimensions of veritable hallucinations, domination of the mental sphere by delirious ideas, culminating in impulsive, explosive acts; impairment of the will, imperfect development of the moral sense, with consequent impairment of the ability to distinguish right and wrong; and, finally, inordinate egoism and total lack of power to take an impersonal view of anything. The affection may occur in either men or women, but is more common in the former. It is to be confounded neither with nymphomania nor satyriasis, because the generative instinct seems to be entirely wanting. It is an affection of the imagination, a morbid extravagance of the ideal. In its individual manifestations it presents the characters of a love, pathologic and essentially psychic, and devoid of carnal appetite. There is nearly always a tendency to personification. The subject foists his ideality on a living person, or on an inanimate object. Though his intelligence may show him the consequence of yielding to his obsession, he is powerless to resist it. His obsession is usually for one of the opposite sex. Erotomania may disclose itself in youth, but it is really a disease of adult life, coming on after puberty and often ending in dementia. It may

co-exist with nymphomania or some other form of sexual aberration or with mysticism.

4. **Occupation and Tuberculosis.**—The diagram which forms the basis of Huber's paper was prepared by the statistician of the Charity Organization Society of New York City. Fifty-three occupations are considered. The tuberculous death rate of marble and stone cutters is shown to be six times that of bankers, brokers and officials of companies, and is undoubtedly due to the irritation of the respiratory tract by remote, inhaled particles of stone. The mortality among cigarmakers is five times as great as that of bankers, and is due largely to the irritating effects of tobacco on the mucous membranes; but the bad air and the wretchedly insanitary conditions under which these people work are essential factors. Saloon keepers, hotel servants and bartenders show a heavy mortality, as do the hat and cap makers. The tailors and the garment makers, however, have a death rate which would be surprisingly low were it not for the fact that Jews, who, as a race, enjoy a comparative immunity to tuberculosis, monopolize these trades. Glassblowers show the influence of exposure to extreme heat; they are, also, apt to sit for many hours in constrained positions. Among the musicians, the irregular, bohemian life led by many of them is largely responsible for the large death rate, 350 per 100,000. The mortality extremes per 100,000 living in the same occupation are, 92 for the bankers and 540 for the marble and stone cutters.

5. **Cesarean Section in Placenta Previa.**—Douglas attempts to determine the justifiability of cesarean section in the management of placenta previa by presenting a study of methods and results, as follows: De Lee, 30 cases without a maternal death; Fry, equally successful in 14. Hirst collected 104 cases, with a death of only one mother. Sloan Maternity, New York, maternal mortality, 12 per cent. Boston Lying-in Hospital, 75 cases, maternal mortality, 10.16 per cent. Strassmann, in a series of 231 cases, found a maternal mortality of J.25 per cent. Douglas, 12 cases, with a death of two mothers. Dorland collected 88 cases of central attachment of the placenta, with a maternal mortality of 22 8/11 per cent. Schauta finds 18 per cent. of mothers lost in 50 cases of placenta previa centralis. As to infantile mortality, Douglas quotes these figures: Hirst, 50 per cent.; Sloan Maternity, 45 per cent.; Strassmann, 6 per cent.; Schauta, 70 per cent. Fry lost 9 children in his 14 cases, in which all the mothers were saved. Douglas says that in a series of cases of placenta previa one may expect a maternal mortality of 10 per cent. and a fetal mortality of 50 per cent. In central attachment of the placenta, maternal mortality, 20 per cent. and fetal mortality, 75 to 85 per cent. As to the subsequent history of 80 patients who had suffered from placenta previa, Radtke found that 30 per cent. were sterile, 23 per cent. aborted at subsequent pregnancies, 57 per cent. suffered from anemia, vertigo, headache, etc. Endometritis, laceration of the cervix and of the perineum and other pathologic conditions were found present. As to cesarean section for placenta previa, Deaver, in 24 cases, had a maternal mortality of 20 per cent. By selecting from these cases the patients that were proper subjects for the operation, the maternal mortality is reduced to 18.75 per cent. The fetal mortality is reduced to 50 per cent. These are the results in placenta previa with rigid cervices and other unfavorable conditions. Douglas is firmly convinced that the maternal mortality can be reduced below 10 per cent., but does not anticipate a reduction in the fetal mortality below 50 per cent. He says that cesarean section is indicated in cases of central attachment of the placenta in a primagravidia with an undilated and rigid cervix, with moderate hemorrhage, a viable child, and when the operator is a capable abdominal surgeon. The contraindications to the operation are an exsanguinated patient, or one who has been subject to various obstetric efforts, the presence or probability of infection, a dead fetus, and an unskilled operator.

8. **Sulphate of Copper as a Destroyer.**—The investigation carried on by Doty at the New York Quarantine Station covered the following points: 1, The use of copper alone, or in combination with lime, for the destruction of mosquito larvæ; 2, as a deodorant; 3, as a disinfectant. He found that in the destruction of mosquito larvæ and as a deodorant the use of copper in combination with lime is more effective than when used alone. This mixture destroys the larvæ by rapidly removing from the water in which they are contained the organic matter or nourishment on which they depend for life, and that this result is not due to a toxic effect produced by the copper or lime. In swamps or bodies of water covering large areas, where fresh water and organic matter are constantly being added, the use of the mixture is hardly practicable, and its value in these instances is not very apparent. However, in collections of stagnant and offensive water, where the mosquito larvæ are frequently found in enormous numbers, the mixture of copper and lime, one pound of copper and one pound of lime to ten gallons of water added to 500 gallons of water to be experimented with, is of great value, inasmuch as it not only destroys larvæ but deodorizes the offensive fluid. In swamps, etc., where there is usually but little sunlight, and where there is the most active propagation of the mosquito, there is no doubt, says Doty, as to the superiority of petroleum, not only for the destruction of the larvæ but in driving away the winged insects. Doty suggests the use of copper and lime, or petroleum, only when it is impossible to carry out the scientific and radical measures for the extermination of the mosquito; that is, proper drainage and the observance of the laws of modern sanitation. The action of the mixture as a deodorant is rapid and permanent; it is practically harmless, and is cheap and easily made, and seems to comply with the requirements of a typical deodorant. Furthermore, its range of usefulness is extensive, as it can be employed equally well for deodorizing solids or fluids. Experiments to determine the germicidal value of sulphate of copper are now under way in the laboratory of the quarantine station. In tests made with typhoid bacilli in distilled water, tap water, water from sewers, and broth, it was found that in distilled and tap water a solution of 1 to 10,000 killed in one hour. In distilled water a 1 to 100,000 solution killed in two hours, while in tap water it required from six to eight hours to produce the same result. In water taken from street sewers a 1 to 1,000 solution was required to kill typhoid bacilli in one hour, while in broth it required a 1 to 300 solution for this purpose. A 1 to 10,000 solution in distilled water killed the cholera organism in twenty minutes.

10. **Painful Affections of the Feet.**—Ogilvy emphasizes the importance of proper care and treatment of affections of the feet, describing, in particular, eversion, flatfoot, metatarsophalangeal pain, and painful heel. Eversion is the most common deformity. It is usually termed weak ankle. It results in a breaking down of the arch of the foot and flatfoot. An early diagnosis is of importance, for it is very difficult to transform an everted, painful foot with a broken down arch into one which is capable of performing all its functions without pain or discomfort. The treatment of these various conditions is described in detail. The anatomy of the foot and the subject of proper footwear are also considered.

11. **Appendix in Hernial Sac.**—Golding's patient complained of pain in the right inguinal and scrotal regions, vomiting and constipation. Examination revealed a firm, tender tumor i

the right side of the scrotum, over which the skin was red and glazed. The tumor was irreducible, dull on percussion, not translucent nor fluctuating, and gave no. impulse on coughing. Temperature, 99.2; pulse, 88. On opening the sac, about eight ounces of clear straw-colored fluid escaped, and the sac was seen to contain an elongated body about ten inches long and one inch in diameter, which was intimately adherent to it. This body was separated, and on incising it it was found that the appendix occupied its center and was surrounded by a thick mass of inflammatory connective tissue. Golding deems two points in the case worthy of note: 1. The unusual length of the appendix. 2. The similarity in the symptomatology of strangulation and an acutely inflamed appendix occupying a hernial sac.

12. **Medical Inspection of New York City Schools.**—Darlington describes the medical supervision of the schools of the city of New York and the precautions that are taken to prevent the spread of contagious diseases. The Board of Health appropriates annually a sufficient sum to appoint 150 school inspectors at the rate of $30 a month, each inspector being assigned one or two schools. The schools are visited daily, and the inspector examines all children, whom the teacher has sent to his office in the school, suspected of having any contagious disease. Any case of measles or scarlet fever is visited at once by a diagnostician of the department; if the diagnosis is confirmed the usual steps are taken to prevent the spread of the disease. In the case of diphtheria, the inspector secures the material for making a culture. A daily list of all contagious diseases is sent each day to each school in the city, thus enabling the school to send home any child from a family where contagion is reported. Each inspector has about 5,000 children under his charge, whom he is required to inspect once a week. Inspectors must visit all public schools assigned to them before 10 a. m. each school day. The first visit is called the morning inspection, and consists in calling at the schools to inspect all children isolated by the principal as possibly sick with some contagious disease; all children who have been absent from school for a few days; all children excluded from school attendance. A routine inspection consists of a class-to-class examination of each child present. The children march by the inspector, pull down their own eyelids and open their mouths wide, the inspector making a visual inspection as the child passes him. If the child is suspected of having any trouble which is not quite evident, it is ordered to the inspector's office in the school for a more thorough examination. Each child excluded from school is given a properly filled out exclusion card in a sealed envelope furnished by the department. The inspectors are required to make daily reports. The inspector must ascertain from the principal the names and addresses of all children absent from school for a few days for no known reason. These addresses are visited by the inspector to ascertain the cause of absence. Thus many unreported cases of contagious diseases have been found. Janitors and their families are not allowed to occupy apartments in the school buildings. Children with acute eye disease and pediculosis, showing signs that they are under treatment, are allowed to attend class. The nursing system in force in New York was established for the purpose of caring for communicable diseases, such as pediculosis and conjunctivitis. Each nurse is required to keep a record of all cases treated by her and she has to visit at their homes all children excluded from school when they did not return for reinspection on the day appointed by the school inspector: also to instruct parents in the proper way of caring for children's heads at home. Cases attended by the school nurse are pediculosis, conjunctivitis, ringworm, impetigo, favus, molluscum contagiosum and scabies. The diagnosis is sent to the nurse by the school inspector and she treats the cases accordingly, the supplies required for such treatment being furnished by the department of education. At the present time there are nineteen school nurses in the borough of Manhattan. In order that children excluded from school could be followed and watched closely to see that the instructions given them by the medical inspector were observed, a card-index system was adopted. This system provides a card for each class in each school. On this record is kept of every case of contagious disease, with complete data. Because of the many cases of trachoma existing among school children, it became necessary to give the inspectors special instruction for the purpose of becoming better qualified in the diagnosis of this disease, and to establish an eye hospital and dispensary of the department of health. During the school months there were four operators and four clinicians, also two anesthetists. The total number of children treated at this hospital during the year 1903 was 15,936. The inspectors also are required to make throat cultures of all children showing the slightest redness and hypertrophy of the tonsils. Two inspectors are assigned for the work of vaccinating school children. No child is accepted in the public schools unless it can show either a white certificate stating the age on which vaccination was performed, or a yellow certificate of successful vaccination. While the department does not directly compel a child to be vaccinated, it does enforce the law that if the inspector in charge of the school deems vaccination necessary the child must be vaccinated or it will not be allowed to attend school. Darlington mentions the following as being outside of department control: 1. Proper care of the children's outer garments at schools; 2, proper aëration of classrooms; 3, proper lighting; 4, ample accommodation for each child; 5, sufficient playground facilities; 6, establishments of baths in public schools; 7, examination and compulsory care of the children's teeth and aural cavities. Examination and correction of refractive errors; 8, correction of deformity of locomotor apparatus; 9, exclusion of all cases of nervous disease; 10, segregation of children with inferior mentality.

17. **Abuse of Water Drinking in Disease.**—Manges calls attention to some facts in this connection that are not heeded as well as they might be by physicians. The normal quantity of water for a healthy adult, exclusive of the water contained in food, is about 1½ to 2 liters a day. Only a small portion of the water ingested is absorbed by the stomach, the maximum quantity being 10 per cent. The other 90 per cent. is passed on into the intestines. Every drop of water introduced into the system must be excreted from it, directly or indirectly, by the heart; hence, the larger the quantity of liquid introduced, the greater the amount of energy demanded of the heart for its disposal. The functions which are principally affected by water drinking are, first, metabolism; second, temperature; third, circulation, especially the heart; fourth, glandular secretions, and fifth, peristalsis. Diuresis does not depend on the quantity of water introduced into the body, but on the blood pressure from the kidneys. When the heart is no longer competent, the daily quantity of water should be restricted to 1¼ liters, not including the water con-

tained in food. In the earlier stages of nephritis, when good compensation exists, this restriction is advisable as a prophylactic measure. On one day in the week the patient is allowed to drink as much as he pleases. This insures the removal of any nitrogenous salts which might have accumulated. Manges' experience has proved that the results obtained from such restriction of water are decidedly better than those following the unrestricted use of water. In heart disease, the abuse of fluids is less evident, but none the less serious, in its consequences. A routine use of stenciled treatments wrecks many a compensation or converts latent into actual cardiac disease. This is especially true at the various spas. The chronic hyperemia of the kidney, the existence of dropsy and the hydremic plethora and anemia in advanced cardiac conditions are sufficient indications of the need of great care in warning patients against too much liquid in these conditions. The object should be to regulate the blood pressure in the kidney rather than to crowd more work on the already struggling heart by carelessness in fluid regulation. In chronic gastric and intestinal disorders the significance of this abuse can be more regularly recognized. Water has little effect on metabolic disorders. As regards free flushing for the removal of calculi or gravel, etc., Manges advises that we always first ascertain the condition of the circulation and then be sure that the increased intake of water be represented by an adequately greater amount of urine. In acute infectious diseases and in septic conditions we must also guard against the dangers which may follow from crowding too much water at ordinary temperatures. The water should always be given cold, and in frequent, small quantities. He strongly condemns the practice of simply directing the patient to drink as much water as possible without considering the condition of the heart, circulation and kidneys.

22. **Meralgia Paresthetica Following Typhoid.**—In this patient Wedekind found almost complete anesthesia of the external and anterior aspects of each thigh, the outline on each being identical, one spot about the size of a silver dollar, of exquisite hyperesthesia, along the inferior line of demarcation on the right thigh only. Digital pressure produced deep-seated pain like that in the subperiosteal abscess. Myalgesia was general in both thighs and legs after continued exercise, but disappeared completely after a long rest. A spot on the right side of the chest, three inches below and to the right of the nipple, suddenly flared up and burnt for a moment and as suddenly ceased. There was awkwardness and uncertainty in his gait, suggesting partial loss of control of co-ordination. The treatment has been rest, strychnin and massage; the results, not great. The personal history is absolutely negative.

24. **Delayed Results of Wound of Brain.**—O'Hanlon relates the case of a man who, during an altercation, was shot in the head, the bullet entering through the temporal bone. No ill results followed until about the third month afterward, when the man was taken with fits, which recurred at irregular intervals for a period of about fifteen months, when the patient died. Autopsy revealed a bullet resting beneath the anterior lobe of the right hemisphere at the base. The track of the bullet was plainly visible through the brain tissue, beginning at the left frontal lobe. An examination of that part of the brain, broken down into an abscess, showed a small piece of lead, to which adhered a sharp piece of bone, which had set up the irritation resulting in the formation of the abscess.

27. **New Gastroenterostomy.**—Gould has devised an operation for gastroenterostomy which is founded on the following principles: 1. That the pylorus should never be closed merely to insure the patency of the artificial opening. 2. That the gastroenterostomy opening should be so constructed that it will remain open of itself. 3. That an enteroenterostomy should be performed between the proximal and the distal coils of the jejunum. 4. That as much as possible of the food should be prevented from entering the stomach without entirely cutting off the jejunal patch from the protection of the bile against the eroding effect of the gastric juice. The stomach is delivered, and the posterior wall is exposed in the usual way. The mesocolon is torn through for a distance of two and a half inches in a direction parallel with the blood vessels and opposite the lowermost point of the greater curvature. The stomach clamp is applied at right angles to this curvature, taking up a fold about three and a half inches in length, and leaving a margin of one inch between the end of the fold and the greater curvature. The fold is incised and the redundant mucous membrane is removed in the usual way. The edges of the incision are seized with forceps at points midway between the two angles and pulled apart as far as possible, thus making the incision run parallel to the greater curvature. The stomach clamp is again put on, leaving a good margin of free edge for subsequent sewing. The ends of the incision, as originally made, will now be placed in the middle, and will have a tendency to sag unless clamped tightly. The jejunum is brought out and a longitudinal fold three inches long is clamped about ten inches from the beginning of the jejunum. The first seromuscular stitch is next placed. Each end of the continuous stitch is left long for future use. The jejunum is opened at a point opposite the middle of the stomach incision and enlarged a short distance either way gradually, until the corners of the stomach and jejunal openings are exactly matched. The cut edges are sewed together with a No. 0 chromic continuous stitch, which starts in the middle of the incision, half way between the two corners, and goes outward to the corners on either side. The first corner is turned and the thread tied. After turning the second corner the stitch is carried over the front and tied to the end left at the first corner, making a perfectly firm and accurate approximation of both corners. The clamps are removed and the rough edges on the front of the suture are buried with a continuous seromuscular stitch. The long end left by the first seromuscular stitch is commonly used for this stitch over the front. An interrupted seromuscular stitch is placed at either angle of the anastomosis, about one-quarter of an inch away, as an extra support. The edges of the incised mesocolon are finally caught down with interrupted stitches to the stomach around the anastomosis. Gould next makes what he deems a successful and permanent valve by inverting the intestine transversely instead of longitudinally. This technic requires three or more layers of sutures; the first are interrupted mattress stitches placed around the circumference of the gut as if an end-to-end suture had been made. This rolls in the bowel circumference and forms a circular constriction. The interrupted stitches are followed by two layers of continuous stitches, which turn in still more of the bowel and thus make a small diaphragm across the lumen. By this procedure the proximal coil is shortened about three-quarters of an inch. The site of the valve should be about three and a half inches below the gastroenterostomy. A lateral anastomosis is made about one inch below the valve. Before closing the anastomosis, the clamp is removed and a blunt instrument introduced upward in the coil to ascertain whether the artificial diaphragm is wide enough to obstruct the lumen. If the inturned edge is too scanty, another continuous stitch is placed around the bowel until exactly the proper amount of obstruction has been made. The enteroenterostomy is then completed and the abdomen closed.

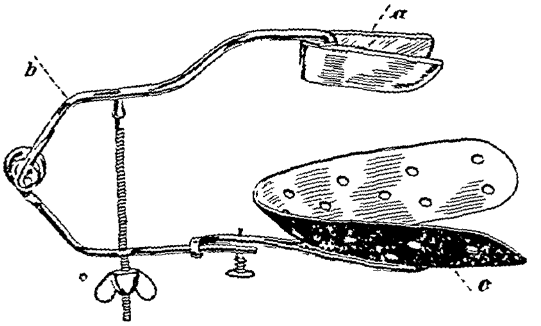
37. **Adjustable Metallic Interdental Splint.**—Matas' splint is constructed on the principle of a clamp which holds the entire projecting arch of the jaw (from the chin to the angles) firmly in the grip of a flexible mouthpiece which fits like a gutter over the entire dental arch; and of an external plate or chin cup, which extends from the symphysis to the angle. The mouthpiece and chin plate are both detachable. The chin cup is made adjustable to various degrees of prognathism by a sliding joint fixed by a pin and thumbscrew. The appliance consists of three component parts: 1. The mouthpiece or dental splint proper (*a*), which is hollowed in three planes to fit loosely over the crowns of the teeth, the groove or gutter broadening from before backward to correspond with the increasing diameters of the molars. The edges of the splint form two flanges or rims, which project downward; the outer flange extending to the neck of the teeth on the outer or buccal side, the inner flange or rim dipping to a lower level, almost touching the gums on the inner or lingual side. This splint is made of block tin and is indented approximately on a level with the bicuspids by two deep cuts which penetrate the gutter to its outer rim, leaving a narrow wedge-like space which is closed at the apex by the outer or labial rim of the splint. The softness and flexibility of the metal of which the splint is made, together with these (Wiley) cuts, allow the operator to adjust the splint to the varying contour of the lower dental arch as it is met in different individuals. The splint is made in three different sizes, for children, for young persons and for full-grown adults. The breadth of the gutter can be altered by stretching and modeling the flanges. The dental gutter is also provided with a deep groove or slot in the center of its inner or labial surface, which fits the hook at the tip of the clamp and holds it very firmly in position when it is locked. 2. The chin piece (*c*) is made of perforated aluminum and is shaped to fit the contour of the jaw. It can be moved backward and forward on a sliding joint, which is adjusted by a thumbscrew and is attached to the lower limb of the clamp. In order to prevent injurious pressure on the skin of the chin, it is padded with cotton, covered with a layer of gauze, and smeared with zinc oxid ointment. 3. The clamp (*b*) which holds the mouth and chin pieces together is made of soft steel and consists of an upper and lower limb, screwed together at a considerable distance in front of the mouth. The upper limb projects from the middle of the mouth and is curved over the lower lip so as to allow the mouth to be closed, a very necessary provision to prevent salivary dribbling and to permit a complete control of the mouth in eating and drinking. The pressure required to hold the jaw firmly in the grasp of the intrabuccal and extrabuccal pieces is obtained by a screw attached by a swivel joint to the upper limb of the clamp, the pressure being regulated by a thumbscrew which acts on the lower limb of the appliance. The chief object of this splint is to immobilize the broken fragments of the jaw without restricting its movements as a whole. It is especially intended for compound fractures of the maxillary arch, whether single or multiple, in which there is a marked tendency to recurrent displacement, and which require frequent inspection and antiseptic irrigation of the aural cavity.



38. **Wounds of the Liver.**—Tilton considers the injuries of the liver and discusses their special signs, prognosis and indications for treatment. The modern tendency is toward early laparotomy. Open wounds should, without exception, be treated by enlargement of the wound, exposure of the liver, and determination of the site and extent of the injury. Care should be taken to examine the entire liver, as a second wound may remain unnoticed and give rise to fatal bleeding. The best methods of stopping hemorrhage are by the use of sutures or gauze packing. If the former are used they should include considerable liver tissue at the edges of the wound and, if possible, go down to its full depth. Gauze packing is particularly suitable for contused wounds, gunshot wounds, and punctured wounds, and is, furthermore, a useful addition to suture. The thermocautery is of very little value in arresting hemorrhage from the liver. The blood and bile can easily be removed by flushing the abdomen with hot saline solution or by dry sponging. Drainage is employed in subcutaneous wounds chiefly for the purpose of arresting hemorrhage. In gunshot and stab wounds with a dirty instrument, it is a valuable means of preventing local infection of the organ or general infection of the peritoneal cavity. As regards subcutaneous ruptures, the mild cases without marked symptoms of collapse or of internal hemorrhage should be treated expectantly.

42. **Penetrating Wounds of Abdomen.**—Hupp reports six cases, 5 of them pistol shot wounds and 1 a stab wound.

43. **Hepato-Cholangio-Jejunostomy.**—Maylard's case was a man, aged 52 years, who complained of pain in the epigastrium and vomiting. The onset of the symptoms was attributed to an accident which occurred twenty-two years previously, when he was struck over the lower ribs on the right side. This was immediately followed by severe pain at the seat of the injury, which continued for several weeks. After that he was subject to intermittent attacks of pain, some of which were exceptionally severe, and on one occasion the attack was accompanied by hiccough and vomiting lasting for twelve days. He generally noticed, after an attack, some yellowness of the skin and conjunctiva, and once there was severe jaundice which lasted for three weeks. On opening the abdomen, Maylard found that the gall bladder was replaced by a shrunken, indurated mass of tissue, embracing the liver, the pyloric end of the stomach and the hepatic end of the

transverse colon. The stomach was not dilated. Neither the pylorus nor the first two inches of the duodenum were obstructed. No constriction could be detected in the colon, but directly opposite the most marked indurated mass a slight indentation was felt, suggestive of the possible healing of an opening through which a gallstone might have passed. There being no obstruction anywhere, the wound was closed. The patient continued in good health for nearly four years, when jaundice set in and he also commenced to suffer from a general constitutional deterioration. There was a marked ventral hernia at the upper part of the median cicatrix. The urine was deeply bile stained and the feces clay colored. Seven months later Maylard undertook to establish a communication between the dilated ducts in the liver substance and the duodenum. The abdomen was opened along the course of the old transverse cicatrix and the incision extended. Extreme matting was encountered. The liver was much shrunken, of a deep mottled purple color and lay high up under the ribs. With much difficulty the jejunum was stitched to the margin of the liver for about two inches by means of a continuous sulphochromic-gut stitch. The liver was then incised for about one and one-half inches, the bowel opened for the same extent, and the opposing surfaces beyond the two cuts were united by interrupted stitches. In order to avoid tension on the stitched gut, the bowel was anchored at the upper part to some adherent omentum. A separate incision was made posteriorly to drain the right lumbar fossa. The patient made an uninterrupted recovery from the operation, but died about a month later from slowly increasing emaciation and weakness. There was no postmortem. On the second day after operation the stools were somewhat darker in color, but further than this no change seemed to have occurred in the general condition of the patient. Maylard concludes that this operation may be safely undertaken without fear of any immediate or comparatively remote dangerous results.

45. **Operation for Inguinal Hernia.**—The facts which Scudder considers important in the operation for the cure of an inguinal hernia are: An ample cutaneous incision; absolute hemostasis; an anatomic dissection of the parts concerned, so that every structure is clearly recognized; the complete isolation of the neck or abdominal portion of the sac; the complete emptying of the sac of both adherent and non-adherent contents; the suture of the hernial sac at the level of the peritoneum of the anterior abdominal wall; the exact suture of the abdominal wall superficial to the peritoneal sutures, including always one or two sutures placed over and above the sutured sac; the minimum of trauma to the cord. He says he has never yet found it necessary or advisable to excise the veins of the cord. Occasionally he has not transplanted the cord in children, and under certain circumstances has not transplanted it in adults. He considers it of comparatively little importance whether the cord is or is not transplanted. He says that he is more and more inclined not to transplant it. He has utilized the fascia of the rectus abdominis a few times to re-enforce the abdominal wall above the inner end of Poupart's ligament, as illustrated by Halsted, but the elaborate method of suture used by Halsted he considers unnecessary, except in unusual cases. After operation by his method the patient is in bed two weeks, on a bed-rest the third week and out of bed the fourth week. A bandage is worn for one month, after being up and about, for the comfort it affords. The operation is described in detail.

48. **Matas Operation for Aneurism.**—Gessner reports the case of a negro, aged 32, suffering from an aneurism of the right popliteal artery, involving the middle and lower portions of that vessel. The tumor was five inches in the long axis of the limb, by four and a quarter inches transversely. He gave a history of syphilis four years before with one year's treatment. The aneurism was treated after the method advocated by Matas, slightly modified to the extent that the walls of the aneurismal sac were brought together directly instead of being turned in on themselves after the method of Neuber. The operation proved successful.

4. **A New Blood Fluke.**—When Catto was quarantine officer at Singapore cholera broke out on a passenger ship from China. Some 400 coolies were quarantined. Among them was a Chinaman who presumably had never been away from China before. He died after three days' illness. During life it was found that the right lobe of the liver extended two fingerbreadths below the costal arch. The left lobe was a handbreadth below the sternum, and its percussion dullness merged into the splenic. The spleen was palpable one inch from the iliac crest, and its notch was in line with the anterior axillary fold. The autopsy was held an hour and a half after death. The adipose tissue throughout the body was a prominent feature. The appearance of the peritoneum suggested repeated attacks of peritonitis. The appendices epiploicæ were thickened and in some places matted together. The rectovesical pouch was almost obliterated. Encasing the large intestine was a coat of fat, most marked at the mesenteric attachment. The mesenteric tissues were all thickened and loaded with fat. The liver was uniformly enlarged. Its surfaces were markedly nodular, its borders sharp and irregular, the whole presenting the appearance of a very coarse cirrhosis. Its consistence was greatly increased, but its color was not appreciably altered. The coats of the gall bladder were thickened, and a layer of fat almost completely encased this viscus, which was distended with clear, mucoid, apple-jelly-like material, containing several minute black gallstones. The colon was much thickened. The mucous membrane was swollen, hyperemic and friable, presenting numerous small, circular, superficial erosions and patches of necrosis. The outer coats were very tough, almost cartilaginous, and showed no tendency to ulcerate. The rectum was three-quarters of an inch thick all around and was adherent to the bladder. It nearly filled the true pelvis. Where adhesions had formed, the bladder walls were thickened, but elsewhere it was healthy and nowhere was the vesical mucosa diseased. The sigmoid was uniformly thickened; in tracing the bowel upward the thickening became less marked and more patchy. The coats of the cecum and the appendix vermiformis were hypertrophied, the mucous membrane presenting small patches of ulceration and necrosis. The appendix was provided with a mesentery, and a distended lymphatic could be recognized running along its free surface. The liver and bowel cut gritty on section. The enlarged spleen was pigmented. The stomach, pancreas, suprarenals, kidneys, heart and lungs showed no signs of coarse disease. Sections of the liver and mesenteric lymph glands involved were found to contain numerous small oval bodies having a smooth, stout capsule. Sections of the intestine made later showed ova and filariform embryos in bundles in the mucosa and villi of the large intestine. Subsequently, in sections of the mesocolon, Catto found adult trematodes, male and female, in the blood vessels, the ova in the uterus of the female corresponding in every particular with the oval bodies found in the various viscera. The life-history of this new schistosome corresponds with that of other trematodes, especially the *S. hematobium*. It differs from the latter in that (1) the habitat of *S. hematobium* is said to be venous only, whereas the habitat of the new schistosome is mainly arterial; (2) the ova of *S. hematobium* affect mainly the urinary system and escape from their human host by this channel. In the new species the ova apparently affect exclusively the alimentary system, escaping by this route from their human host. The geographical distribution differs, for no case of bilharziosis has yet been met in China. Catto describes the new organism in detail.

6. **Ambidexterity.**—Harman considers the influences determining our general right-handedness and, incidentally, the persistence of cases of left-handedness. He also demonstrates the present existence of a very general degree of ambidexterity or, rather, co-ordination of function in the arms.

7. **Cutaneous Anthrax Treated by Sclavo's Serum.**—Lockwood and Andrewes report the case of a worker in horsehair suffering from malignant pustule of the cheek. Forty c.c. of Sclavo's serum were injected subcutaneously into the flank and abdomen, and no other treatment was adopted. The tem-

perature was then 102.4, and it rose in the evening to 103; the pulse was 92. During the night the temperature fell to 98.6. For the next two days the patient showed little improvement. The slough increased somewhat in size, and the surrounding edema became much more marked, at times almost closing the eye. The enlargement of the glands at the angle of the jaw increased considerably. There was also some swelling and redness of the fauces. The patient's general condition was good, and no further dose of the serum was given. Three days afterward there was distinct improvement. Seventeen days after the administration of the serum only a small granulating surface was left, which appeared likely to leave a scar scarcely more serious than that resulting from vaccination. The serum treatment thus proved completely successful.

8. **Nitroglycerin in Surgery.**—Elvy calls attention to the value of nitroglycerin in surgical cases, administered in doses of gr. 1/100. He advises its use in incipient senile gangrene and in all cases of impaired circulation in which contracted arterial walls are present. Even when the arteries seemed to be normal he has used the drug with benefit in local congestion.

15 Diet in Chronic Diseases. John Haddon.

9. **Recurrent Effusion into Knee Joint.**—Bennett considers 750 cases in which the effusion was recurrent, either spontaneously or after another injury, generally so slight that its effect on the normal joint probably would have been unnoticed. He divides his cases into two groups: 1, those entirely independent of any constitutional conditions (509), and 2, those influenced by constitutional conditions (241). In 428 cases in Group I the proportion of males to females was 16 to 1. The youngest patient seen was 9 years old and the oldest was 72. The left knee was concerned in considerably more than half the cases, while in 15 both sides were involved. With one exception, the trouble in the second knee followed that in the first after an interval. The symptoms arising from lesions of the outer side of the joint were less acute than those connected with defects on the inner side; it was also noticed that when the outer semilunar cartilage seemed at fault the symptoms of pain and locking were referred to the popliteal space in at least half the cases. In all such cases operated on recovery followed the removal of the obviously displaced anterior part of the semilunar cartilage. In the total number of 428 cases the symptoms pointed to the inner side of the joint being concerned in 304; to the outer side in 113, and to both sides in 11. Eighty patients were operated on (see Group 2). Fifty-six cases presented no other symptoms than mere recurrence of effusion without noticeable further injury. The affected knee occasionally swelled up without any apparent reason and without inconvenience beyond a slight feeling of weakness. The original effusion had, with two exceptions, come on after a twist or sprain of so slight a kind that it attracted little or no attention at the time. In 12 of these cases which were subjected to operation the internal semilunar cartilage was found to be detached and displaced in 5, the external in 1, and in 1 both cartilages were displaced. In the remaining 5 cases operated on nothing abnormal was detected. Of the 44 cases which were not operated on 30 were treated with complete success by massage, exercises, electricity, etc.; in the remaining 14 the ultimate effect of the same treatment is not known. Bennett says that in recurrent effusion into the knee-joint after injury, independent of constitutional conditions, when the usual methods of treatment had failed to effect a cure, exploratory operation is indicated on the grounds of the probability of internal derangement existing and that extensive displacement of one or even both semilunar cartilages may take place without the recurrence of any of the symptoms which are commonly regarded as characteristic of the lesion. In 21 cases loose bodies were found in the joint. The injury in each case was severe and was followed by excessive immediate swelling. In 14 cases operated on a single fibrous loose body was found in each, the smallest being of the size of a horse-bean and the largest of the size of a cherry. In one of the two remaining cases two oval bodies were found; in the other it was evident that the body had been broken off the edge of the articular surface of the femur. Generally speaking, the larger the body the less acute were the symptoms, although the attacks appeared to be more frequent. Only 4 cases of genu valgum were met with in the series. The injury in all cases was indirect, and in each a rapid increase in the deformity followed. In the second group of cases the existence of a constitutional dyscrasia exercised a considerable influence (1) in leading to the occurrence of symptoms from very slight causes and (2) in rendering recovery difficult or impossible unless the constitutional conditions are treated or, at all events, taken into account. In 107 of the 241 cases comprising Group 2, a diagnosis of osteoarthritis was made. In about 50 per cent. the diagnosis was only arrived at with certainty after repeated recurrence of effusion had been followed by some characteristic sign of articular change. The initial injury was invariably slight and generally indirect. In only two cases was a loose body felt before operation; in the remainder attacks of acute pain led to operative investigation: in all the cases explored the loose bodies were found and removed through a longitudinal incision at the inner side of the joint. Males were affected largely in excess of females (4 to 1), the right knee being concerned more frequently than the left. In the treatment of these cases nothing seemed to have more than a palliative effect, excepting the radiant heat bath, massage and electric vibration, which in 23 cases of comparatively recent origin appeared to effect an actual cure. In 30 cases rheumatism and gout acted as underlying causes. In the rheumatic cases a cure was effected, as a rule, by the usual constitutional treatment combined with massage. Operations were performed for the relief of acute pain due to tension; incision appeared to possess no advantage over aspiration, while the healing of the wound after incision was slow. Forty-two cases gave a history of syphilis, the longest period between the original infection and the injury causing the effusion into the knee was 28 years; the shortest period was 3 years. The syphilis in all cases appeared to have been cured. The injury was direct and, as a rule, slight. The right knee was affected more often than the left. In no case was permanent benefit derived until a course of antisyphilitic treatment was adopted. Gonorrheal rheumatism was a factor in 28 cases, malaria in 18, and hemophilia in 3. In 13 cases there was a passive effusion into the joint, such as is prone to occur in young girls during adolescence, if the menstrual arrangements are irregular and, especially, if they are delayed in their onset.

12. **Rainy Winds and Phthisis.**—Gordon finds on investigation that strong rainy winds appear to be remarkably associated with increased prevalence of phthisis, while absence of such winds seems to correspond strikingly with rarity of phthisis.

17. **Hydrogen Dioxid in Form of a Stable Powder: Sodium Perborate.**—Jaubert announces the production of a powder which, dissolved in water, generates pure hydrogen dioxid. The powder is obtained by the action of boracic acid on sodium peroxid, and he proposes to call it "sodium perborate." The peroxid of hydrogen generated when this powder is di

solved in water is chemically pure, and its action is reinforced by the antiseptic properties of the sodium borate. Two pounds of the sodium perborate contain nearly 80 liters of active oxygen. The powder keeps perfectly and can be applied dry to wounds, cavities, etc., the nascent oxygen escaping as it comes in contact with the secretions, or it can be dissolved and thus produce a fresh and potent supply of hydrogen dioxid as required. The perborates of zinc, strontium and calcium can be made in the same way. Robin supplemented this communication with a reference to his suggestion that hydrogen dioxid be used for the water of crystallization, mentioned in these columns on page 83 of the last volume, with reiteration of the importance of the nascent state for the efficacy of drugs.

22 *Perforations spontanées de la vésicule biliaire calculeuse dans la cavité péritoneale libre. A. Hallet (Liège).

19. **Dissecting Phlegmonous Perivaginitis.**—Acconci reviews 29 cases in the literature and describes one personally observed. The patient was a healthy iii-para of 29, who was taken sick with evening chills and fever, intense headache, cough and blood-stained sputa. A month later there was a fetid discharge from the vagina with protrusion of what appeared to be a cancerous growth, projecting for from 6 to 7 cm. The fever became higher, the chills more severe, with subdelirium and profound prostration suggesting the typhoid state. This continued for a few days, when suddenly the entire mucous lining of the vagina came away in one piece. After the expulsion of the mass formed by the detached vaginal mucosa the patient rapidly recovered, except for hematometra and two fistulæ, which were cured by an operation later. The affection was evidently primary. The vast perivaginal infiltration did not involve the peritoneum. Only 5 of the cases on record terminated fatally, one probably from pyemia, the others from resulting complications. If diagnosed in time, the perivaginal infiltration might be drained away by scarifications or by incision. This has been done in a few cases and the vagina saved. If seen too late for this, measures to prevent strictures or to cure the consequences are all that can be done.

21. **Prophylaxis of Postoperative Recurrence of Hydatid Cysts.**—Injection of some fluid capable of killing the echinococci before attempting the extirpation of the cyst is a most important means to prevent recurrence later. Its efficacy is confirmed by the experimental tests reported.

22. **Perforation of Gall Bladder into Abdominal Cavity.**—Eleven patients recovered out of 15 operated on after spontaneous perforation of the gall bladder containing stones. This list includes 2 recoveries in Hallet's experience. The conclusions of his monograph on the subject emphasize the importance of prompt operative treatment when cholelithiasis does not yield to medical measures. This is the only certain safeguard against the dangers of perforation later.

23. **How to Apply the Cast in Pott's Disease.**—Calot is in charge of the Berck-sur-mer children's sanatorium, and he asserts that the successful treatment of Pott's disease is merely a question of applying the cast properly. He describes in detail his simple and practicable method of applying the cast. The article is illustrated by 24 cuts. He reiterates that with casts prepared by this technic he is able to cure every case of the disease wherever its location, even when paralysis is present.

29 *Die Anwendung des Adrenalins in der chirurgischen Praxis. Hildebrandt.

24. **Origin of Emphysema.**—Orth has observed 2 cadavers in which the findings indicated that emphysematous degeneration had developed on a basis of congenital hypoplasia of the lung. One lung exhibited this condition with no traces of coal dust in one case, while the other lung was hypertrophied and contained coal dust and no traces of emphysema. He regards this absence of coal dust as conclusive that the lung had not participated in the breathing at any time. He thinks it probable that some injury of the lung tissue, reducing its resistance and elasticity, must precede the development of emphysema.

26. **Objective Heart Findings After Angina Pectoris.**—Kernig has long taught that angina pectoris is due to thrombotic and embolic processes in the coronary arteries, and that the coronary sclerosis is liable to induce foci of softening or infarct in the myocardium or to involve the pericardium in inflammation by allowing the passage of bacteria through the walls of the smaller vessels. The heart findings frequently confirm this assumption and impose the necessity for repose as the proper treatment of thrombosis and embolism. It is only in the severer forms of angina pectoris that such positive findings can be obtained, as a rule. He describes typical examples of such findings. In one group slight fever was noticed after the attack, with appreciable enlargement of the heart, both subsiding under complete repose. In one case the attack was followed by temperature of 37.5 C., with pulse of 84, 90 and 96, the heart found progressively broader after each attack. In another case there was dullness in the left second interspace, but this dullness was not apparent immediately after the attack, but developed in the course of the second day. The heart sounds were very loud in this interspace, close to the sternum, while they were very weak in the fifth interspace. No pericardial friction sounds were heard at any time. He accepts these findings as evidence that the left auricle had become enlarged. This enlargement has been experimentally established as an almost inevitable consequence of occlusion of the coronaries. Circumscribed dullness in the second left interspace, close to the edge of the sternum, is one of the most constant signs of mitral stenosis, according to his experience. The third group includes 5 cases in which acute pericarditis followed the day after the attack of angina pectoris. Huchard found 7 cases of recent pericarditis in his compilation of 185 cases of angina pectoris which came to dissection. The list included also 11 cases of chronic pericarditis and 14 of rupture of the heart. In 2 other cases in Kernig's experience the heart did not present any physical findings, but functional disturbances were manifest after the attack of angina pectoris, oliguria, edema, etc. They illustrate the transitional forms between the cases with positive findings and those in which the angina pectoris does not seem to be followed by any disturbances. In 9 cases published by Pawinski an attack of angina pectoris had preceded the pericarditis, and yet he ascribes the angina to neuritis of the cardiac plexus, although no other evidences of such neuritis were forthcoming. Kernig is convinced that he has saved many patients from sudden death by ordering absolute rest in bed for days or weeks after a severe attack of angina pectoris, when the objective findings suggested the possibility of impending trouble.

29. **Adrenalin in Surgery.**—Hildebrandt reviews the history of adrenalin and extols its advantages for the surgeon. Combined with cocain it insures anesthesia with very much smaller doses, while it prolongs the action of the anesthetic and reduces its toxicity. Subdural injection of cocain is fatal for the rat in a dose of .018 gm., while addition of adrenalin raises the lethal limit to .11 gm. Bier has announced that the addition of adrenalin robs spinal cocainization of all danger, but some fatalities have been reported from this technic. In one obstetric case Bier's directions were closely followed, but the

patient succumbed. König has frequently found adrenalin a great help in plastic operations on the urethra, to prevent the annoying bleeding from the bulb. Analgesia of the mucous membranes is readily attained in five minutes by dabbing the part with a 5 per cent. solution of cocain or beta eucain to which a few drops of 1 to 1,000 adrenalin have been added. To anesthetize the bladder 1 c.c. of suprarenin is added to a .1 or .2 per cent. solution of cocain, analgesia being complete in about fifteen minutes. The fluid must be withdrawn afterward. In operating on the skin or subjacent tissue, Schleich's infiltration method can be used, adding 10 drops of adrenalin to 50 c.c. of the fluid. A still better technic is to make a circle of injections of the fluid around the field of operation. This requires a little stronger concentration, about .05 to .1 per cent. solution of cocain or eucain, with from 5 to 10 drops of adrenalin to the 50 c.c. A circle of blisters is made around the field, at some little distance from it, and the canula is then inserted in the subcutis and the surrounding tissue infiltrated, thus enclosing the field in a complete ring. By this technic it is possible to resect the ribs without pain, infiltrating the subcutaneous cellular tissue and the musculature down to the pleura, in the interspace just above and below. A longer interval is required, however, when such extensive excision is contemplated. The larger, superficial nerves can be deadened in ten minutes by injecting across their course a few c.c. of a .2 per cent. cocain-adrenalin solution. There is danger of later necrosis of the tissues if strong concentrations of adrenalin are used. Gangrenous phlegmons have been known to occur after injection of a few drops of a 1 to 5,000 solution. After-hemorrhage is also possible, as its effect subsides, if in such strength that the lumen of large vessels is closed. Both of these evils are avoided when the circulation in the capillaries alone is interrupted. For this a dilution under 1 to 10,000 is sufficient.

34 (No. 52.) Automatic, Hinged Extension Pulley.—Eine automatisch drehbare Extensionsrolle. A. Hofmann (Freiburg).

30. **Treatment of Tuberculous Ascites.**—Schömann used to treat tuberculous ascites by laparotomy in appropriate cases and found the results of the operation always gratifying. But the necessary narcosis and the long rest in bed afterward render it a serious intervention for debilitated patients, and he has found that the same or even better results are attained by mere puncture and *injection of a 1 to 5 per cent. glycerin* emulsion of iodoform. The slow withdrawal of the ascitic fluid does not harm the weakest patient, and the symptoms rapidly subside after injection into the free abdominal cavity of from 1 to 2 cg. of the emulsion, repeated in from four to eight days, increasing the concentration and dose. He has treated by this technic 7 girls from 2 to 19 years old, all out-patients, and all could be regarded as cured in the course of from three to ten weeks. In [illegible] cases the serous exudation did not recur, but the oldest patient required five injections and the others three or four. She presented an apical *infiltration* with evening temperature and night sweats. The fever vanished after the third injection, the night sweats ceased and the lung lesion healed. She has been in good health since the end of treatment in September, 1902. There were no indications of iodoform intoxication in any instance and no complications or inconveniences of any kind.

31. **Ambulant Treatment of Fractures of Femur.**—Kofmann applies to fractures of the femur the cast used by Lorenz for coxitis. It extends below the knee and is applied in deep narcosis. The foot is held a little distance above the ground by side irons fastened in the cast with a crosspiece below the sole. He keeps a number of these irons constantly on hand, with an assortment of wooden sandals with soles and heels about two inches thick. One of these sandals is tied over the patient's shoe on the sound side. Thus equipped, the patient is able to walk about by the second day and is dismissed from the hospital by the third. In five or six weeks he returns to have the cast removed. In every instance the fracture has been found to be healed perfectly without the slightest deformity of the limb. In a few cases hemorrhage prevented the immediate application of the cast. He applied two sacks of sand on each side of the fractured limb. Their constant pressure soothed the pain and arrested further hemorrhage; the cast was then applied as usual. If the tissues appear too much compromised to be enclosed in the cast, he leaves an opening in the cast over this part for supervision of the healing processes.

32. **Large Pointed Foreign Bodies in Upper Esophagus.**—Kramer was able to accomplish the removal of a plate of false teeth which had lodged in the esophagus, without opening the latter. The corner of the plate had caught in the mucosa and all efforts to dislodge it had proved unsuccessful. He exposed the esophagus through an incision about 9 cm. long on the left side of the neck. The point of the plate could be readily palpated through the wall, and by manipulations through the wound with two fingers of the right hand and pressure with the left hand on the right side of the neck, he was able to dislodge the plate. The patient's retching then brought the plate up into the throat, whence it was readily extracted through the mouth. In the second case there was no effort at retching. When the plate was once dislodged by the manipulations it was extracted with a long, curving pair of forceps. The latest compilation of cases of foreign bodies in the esophagus (Balacescu) states that 69 out of the total 326 cases terminated fatally.

33. **A New Cystoscope.**—Freudenberg calls attention to two features which, he thinks, commend his cystoscope. The lamp and lens are on the convex side of the shaft, which has many advantages. The other new feature is that the optical part can be removed and with it the dividing wall between the optical part and the rest of the interior. Three illustrations show the details of the instrument.

35. **Injury of the Uterus and Rupture During Pregnancy.**—Baisch thinks that the weak spot resulting from some previous injury is responsible for the occurrence of rupture during pregnancy. He reports a case in which the wall of the uterus had been perforated with the finger during the extirpation of a placental polyp. The woman recovered without further intervention, but excessive hemorrhage from *placenta previa* at a delivery two years later compelled hysterectomy. At the spot of the former perforation there was a thin scar, free from muscle tissue. If rupture had occurred at this weak point the scar would probably have escaped attention.

38. **Early Diagnosis of Pregnancy.**—Sarwey's communication on the possibility of detecting the fetal heart sounds long before the time accepted as possible in the text-books, was summarized in The Journal, on page 1425 of the last volume.

He here describes 2 additional cases, which bring the number to 14, in which he was able to diagnose the pregnancy before the eighteenth week. The auscultation has to be perseveringly kept up, with all the precautions enumerated, the bladder completely emptied. In one case auscultation of the heart sounds at the sixth month revealed the existence of twins and established further that the trauma of birth is able to affect the heart to some degree.

39. **Treatment of Climacteric Hemorrhages.**—Queisner has cured 2 cases of climacteric hemorrhage, rebellious to all other measures, by slitting the lower segment of the uterus and suturing the two halves to the freshened roof of the anterior vagina. This allowed easy access to its entire interior and the mucosa was then cauterized with the actual cautery, with the complete arrest of the hemorrhages. This operation is less radical than hysterectomy, and answers the purpose fully as well in these cases. The patients were kept in bed only for four days.

40. **Galvanism as Supplement to Colpeurynter in Treatment of Chronic Inversion.**—Jaworski combines the electrode with the colpeurynter, the tip of the cathode terminating in a bag filled with water, the whole covered with a square of gauze. He gives illustrations of the instrument and relates its successful application in an old, inveterate case of inversion.

41. **Minor Points in Antisepsis.**—The fluid in which Wille keeps his instruments is water containing 1.5 per cent. borax, 3 per cent. carbolic acid and 2 per cent. formalin. The borax prevents rusting, the carbolic acid disinfects, and the formalin disguises the odor of the latter and probably enhances its antiseptic action. Rubber and metal instruments, syringes and brushes, keep perfectly in this fluid and are ready for use at any moment. The receptacle can be of enameled iron, tin or glass. He soaps and rinses the articles after using before replacing them in the fluid. Four years' experience with this fluid have fully established that this antisepsis is all that is necessary. For boiling instruments he uses .5 per cent. borax, wrapping the instruments in a cloth fastened with safety pins. He lifts the package out of the boiling water with bulldog forceps and hangs the package with the same forceps over a nail which projects far from the wall, where the contents dry out, or the package can be wrapped wet in parchment paper to be taken out of the house. After using, they are merely cleansed from blood and wrapped up, ready to be boiled again, thus saving much time. For convenience in wrapping he has his sounds made no longer than the curette, and the speculum is also a third shorter than usual. He keeps his basins in a wooden tub, like a butter tub, in a solution of sublimate. The basins are all of the same size so they fit together. The sublimate solution, with equal parts of salt, does not deteriorate in wood, as in an enameled vessel. For a lubricant, he has discarded oil, vaselin and soap, and uses a jelly made from Irish moss which has exactly the right consistency and is a superior lubricant, while the antiseptics retain their potency in it, as it is made with water. Its greatest advantage, however, is that it washes off immediately without leaving a trace. He keeps it in a wide-mouthed jar in which he can readily insert his hand: it usually has a little salicylic acid or stronger antiseptic incorporated with it.

45. **Pelvimeter on New Principle.**—The relations between the walls of the pelvis, their slant, the position of the symphysis in respect to the promontory and numerous other factors should enter into the measurement of the pelvis from the obstetric standpoint. The new pelvimeter described is an attempt to take advantage of all the various factors which have been established by anatomic-pathologic research. Not a single measurement, but the mutual relations between the various measurements form the criterion. The details of the pelvimeter constructed on these principles are shown in four illustrations. The longitudinal diameter of the symphysis is the base for the calculations. They are simple and when transferred to paper form a complete diagram of the entire interior of the pelvis, obtained without inconvenience to examiner or subject.

46. **Prevention and Treatment of Puerperal Fever.**—Döderlein expatiates on the great value of the aid afforded by bacteriology in the prophylaxis of puerperal fever and in its treatment. About two-thirds of all cases are due to pyogenic germs, we have learned, but there is a large number caused by the putrefaction bacteria alone. He thus distinguishes between the septic and what he calls the sapric puerperal fevers from the Greek term *sapros*, rotten. Prophylaxis is required along different lines for these two varieties. They are very rarely associated. Septic infection is prevented by preventing the access of foreign pathogenic germs, the same as in surgical work. Sapric intoxication is prevented by removing the conditions which the putrefaction bacteria require for their development. These ubiquitous and unavoidable germs are unable to proliferate in an unfavorable environment. The more natural and complete the detachment and expulsion of the placenta the less foreign matter will remain in the uterus to attract bacteria. All measures which require long retention of foreign bodies in the uterus, such as gauze, tampons, laminaria, bougies, metreurynter, etc., afford particularly favorable conditions for the growth of these bacteria and are, therefore, liable to be more dangerous than more forcible measures which are of briefer duration. Puerperal affections will become less frequent the less artificial assistance is rendered and the more the natural defensive and protective processes are allowed to work undisturbed. The primary focus of both septic and sapric puerperal affections is generally in the uterus. Careful supervision of the temperature and prompt disinfection of the focus at the first warning rise will frequently abort the process in its inception, especially if of the sapric variety with fetid lochia. He prefers for the disinfectant a 3 per cent. alcoholic solution of lysoform, and thinks that antistreptococcus serum is indispensable in severe septic cases not too far advanced. Operative treatment of puerperal peritonitis has never proved successful. In selected cases of severe, localized infection of the uterus extirpation of the organ may save an otherwise doomed life. The Trendelenburg technic of resection of septic thrombosed vessels will only exceptionally find application.

47. **Multiple Primary Tumors.**—Grawitz has always contended that it is highly improbable that a single cause can be responsible for all malignant tumors. A parasitic etiology is incompatible with the clinical experiences of multiple primary tumors in the same subject. Even in case of generalized carcinosis or sarcomatosis, in which the blood would be swarming with parasites—if such existed—yet multiple primary tumors are rarely encountered and when found they usually bear the characteristics of metastases, due to deportation of cells and not to the settling of parasites. He recently discovered at the autopsy of a woman of 67 several benign myomas in the

uterus, a malignant sarcoma of the broad ligament with metastases, and a cancer in the small intestine, likewise with metastases. The latter were located in the ovaries, and he emphasizes the importance of search for a primary tumor in the stomach or small intestine in case of bilateral malignant disease of the ovaries. The woman had been in an insane asylum for nearly thirty years, but her physical health had been good until the last year. The microscopic findings speak convincingly, Grawitz thinks, against any parasitic etiology for the tumors observed.

48. Roentgen Treatment of Leukemia.—In the 2 cases reported the leukemic features of the blood and the leukemic enlargement of the spleen and of the glands all rapidly returned to normal under the influence of the *x*-rays. The general health showed marked improvement in the first case, one of myelemia. The other was a case of chronic lymphemia. A patient with splenic anemia treated with the same technic was not influenced. Hard tubes are best adapted for treatment of leukemia, and it might be well to protect the exposed area with a thin sheet of metal foil to filter out any soft rays that may be present.

49. Wear and Tear of the Nerves Without Normal Repair.—In this second article Edinger discusses the abnormal wearing out of the peripheral nervous system without normal repair. The wearing out may be due to relative or absolute excessive functioning or to the influence of some toxin or to a combination of both factors. The resulting neuritis in these cases is a painless affection, sometimes not giving rise to any symptoms or, at most, to a little paresthesia or motor weakness. There is no need to distinguish between the neuritis of old age, of diabetes, infectious diseases or of pregnancy. All belong, Edinger asserts, in this category of wear and tear of the nerves without normal repair, entailing a painless neuritis. Alcohol, lead and arsenic do not attack the nerves directly, but they weaken them so that wear and tear use them up more quickly. No case of acute paralysis after lead, alcohol or arsenic poisoning is on record. In the course of time a hard drinker is liable to present such a using up of so many nerves that the clinical picture of tabes, with or without muscular atrophy, is apt to result, or else a condition resembling progressive neurotic atrophy. This peripheral pseudotabes has many points in common with true tabes. It is due to the wearing out of nerves injured by alcohol, while in true tabes the abnormal wearing out of the nerves is due to their having been injured by the syphilitic virus.

50. Mixed Typhoid and Paratyphoid Infection.—Kayser writes from the "typhoid station" established at Strasburg to help in carrying out the Koch method of combating typhoid by eradicating each focus. He states that the paratyphoid bacterium, type A has been found in pure cultures in 3 cases and type B in 8 cases during the last year. In 15 cases the presumptive diagnosis of typhoid was based solely on the positive findings of 1 to 100 or higher in the agglutination test with the paratyphoid bacillus, type A. Suitable prophylactic measures were at once instituted, although the clinical findings were dubious and all other tests were negative. The course of the disease confirmed the diagnosis of typhoid in every instance except one case, in which the disease proved to be paratyphoid. The specificity of the highest agglutination value is not absolutely reliable unless corroborated by corresponding tests on animals. In typhoid or allied diseases the serum of the patient is liable to be capable of agglutinating not only the bacteria causing the disease, but also others resembling it, the values for the latter sometimes being higher even than those for the specific microbe.

51-52. To Enhance Resisting Power of Peritoneum Before Operations.—Borchardt has been long engaged in study of this problem and now announces that it is possible to materially enhance the resistance of the peritoneum by preliminary injection of physiologic salt solution. He commenced his researches independently of Mikulicz. (See The Journal, xliii, page 1733.) They have established that a preliminary injection of nucleinic acid, horse serum or physiologic salt solution is able to increase the resisting powers of the peritoneum and thus render conditions more favorable for the surgeon. He found that salt solution is fully as effectual as nucleinic acid, and consequently prefers it to the more toxic acid. This preliminary treatment proved most effectual with an interval of forty-eight hours before the operation. The increase noted in the resisting powers persisted for about four days. His results confirm those obtained by Petit, mentioned in these columns, page 1731, of the last volume.

Schmidt writes from the same clinic to report 5 cases in which the foregoing experimental findings were practically applied in the clinic. The preliminary injection of horse serum and salt solution evidently causes a slight irritation of the peritoneum which temporarily enhances its resisting powers In one of the cases related the abdominal wound after the gastroenterostomy separated the seventh day and the bowels protruded, but there was no inflammation and the wound healed without any evidences of reaction. He thinks it is possible that injection of serum or salt solution might be used in the treatment of morbid processes in the peritoneum. It seems to be already established, he concludes, that the dangers may be lessened by it in incipient appendicitis, annexitis, ulcers, etc., re-enforcing the natural resisting powers as an aid to other medical or surgical measures. He gives an illustration of a little instrument which he has devised for injecting the fluid without danger of injury to the viscera. It is in two parts, one resembling an apple corer, a short cylinder trocar, 1 to 1.25 cm. long, with a sharp, slanting, cutting edge and crossbar handle. The other part is a long, round-tipped sound, with a lumen of 2 mm. and openings near the tip. When the short trocar has been introduced through the abdominal wall, the tube is passed through it, and a hole is bored with the blunt tube through the parietal peritoneum, and the fluid allowed to flow through it. Numerous tests on the living subject and on the cadaver have demonstrated that there is no danger from the use of these instruments under normal conditions, but in case of adhesions there is a possibility that in detaching them some of the intestinal content might escape into the peritoneum. He injected always from 5 to 10 c.c. of horse serum in .9 per cent. salt solution (250-500 c.c.) He used this amount of fluid, fearing that a smaller quantity would not spread evenly over the peritoneum. The preliminary injection was generally made from seventeen to nineteen hours before the operation. When the abdomen was opened, part or the whole of the peritoneum was found more or less congested, but there was little free fluid. The leucocytes had increased to about double the previous figure and by the next day to four times.

54. Physiologic and Pathologic Albuminuria.—Senator presents arguments to sustain his assumption that the appearance of physiologic and the closely allied pathologic albuminurias is due to a predisposition which may be congenital or acquired. This predisposition may be the result of an abnormal constitution of various organs, either the kidneys, the digestive tract, the blood vessels or the blood itself.

62. "Heart Bigeminus" After Administration of *Digitalis.*—Fauconnet describes a case diagnosed as recurring endocarditis and mitral insufficiency, in which great irregularity was in duced in the heart action by administration of moderate doses of digitalis. The tracings show the prompt effect of the digitalis in inducing "heart bigeminus," with pseudo-bradycardia. The apex beat indicated 84 systoles, with a 42 radial pulse. Review of the European literature shows that 22 authors have reported double heart beat after the use of digitalis in valvular affections. A number of others have observed it in infectious diseases and during convalescence, one in a case of nephritis, another in catarrhal icterus, one in epilepsy, and one in diphtheria. Three writers have reported it in a valvular affection without digitalis, and 2 without mention of the existing disease. Doll has also reported a case of double beat due to an aneurism in the heart. In the case described in the article the connection between the digitalis and the consequent "heart bigeminus" was strikingly apparent. Fauconnet suggests, in explanation, that the drug exerted its usual effect by inducing more powerful contractions of the heart muscle, filling the cavities better, but the anatomic condition in the heart in severe valvular affections causes this increased action of the heart to be ultimately unfavorable for the organism. The extra systole indicates a maximal contraction of all the muscular elements, while all this expenditure of energy is almost entirely wasted so far as the circulation is concerned. The effects observed have nothing in common with ordinary digitalis intoxication, but they indicate the immediate suspension of the drug. Death may result from disregard of the warning pulsus bigeminus. Salaghi published last July an account of experimental study of the influence of the bigeminal action of the heart on the general circulation. He demonstrated that the double heart action, associated with mitral insufficiency or stenosis, would have the effect—by purely physical laws—of further increasing the stasis in the pulmonary circulation.

64. **Further Research on Causes of Eclampsia.**—This article relates a series of experiments based on the theory of the deportation of villi and syncytiolysis, as connected with the etiology of eclampsia. The results were practically negative.

77. **Analgesia from Subdural Injection of Adrenalin.**—Zeigan found that complete anesthesia below the point was induced in animals by *subdural injection* of 1 mg. adrenalin in 1 c.c. of physiologic salt solution. When the same amount was injected in 5 c.c. of fluid, it spread to the medulla and brain and caused severe symptoms on their part. The anesthesia of the parts below the spot is as complete as when cocain is used, but it does not last longer than eight to twelve minutes. The effects observed indicate mere anemia, not intoxication of the nerve cells. The animals were all lively afterward.

81. **Mechanical Dilatation.**—Muus states that Bossi's dilator had been applied at date of writing 35 times in Meyer's maternity, a larger experience than had been reported from any other clinic outside of Italy. There were 22 primiparæ, and in 7 the cervix was not obliterated, the os allowing the entrance only of a single finger. His experience has convinced him that the Bossi method is able to accomplish delivery rapidly and effectually without causing any appreciable lesions and without danger for the child. The latter can thus be removed from the influences (eclampsia, etc.) for which the rapid delivery is indicated. His impressions from the 15 cases of eclampsia were decidedly in favor of this method of dilatation. Eclampsia before 1890, when delivery was left to nature, gave a mortality of 20 per cent. The mortality during the last six years, in which delivery was hastened as soon as possible after commencement of the convulsions, has been less than 11 per cent. in 43 cases. In 20 in which delivery occurred unassisted 4 of the patients died. In 3 cases of placenta previa 2 patients were promptly and safely delivered by the Bossi method, but the third patient succumbed to pre-existing infection. Muus thinks that rigidity of the cervix is a very serious complication of delivery, and he now follows the rule that if the os remains closed, notwithstanding good labor pains, after the escape of the water, it is not wise to wait too long. Twelve hours should be the maximum expectancy, and the Bossi dilator will then be found more useful than any of the old-style instruments. Four patients with pyelonephritis and 3 with heart disease were smoothly and safely delivered by this means. One woman was admitted moribund and a living child was safely delivered. One of the cardiac patients presented cyanosis and edema, pulse 84, the findings suggesting a congenital valvular affection. As the symptoms were not pressing, nothing was done until labor commenced. Then the cervix was dilated with the Bossi dilator under ether from 2 to 11 cm. in fifteen minutes, and a living child extracted with forceps. The patient has been in good health since, better than for some years previously. Muus regards this case as one of those that best demonstrate the advantages of mechanical dilatation. Without it such demands would have been made on the woman's system in delivering her child that she could scarcely have survived, while with it the delivery was smoothly accomplished in less than half an hour.

83. **Examination of Uterine Scrapings.**—Kaarsberg emphasizes the importance of microscopic examination of the scrapings whenever the uterus is curetted for any cause. He quotes Landau to the effect that 99 out of every 100 women with postclimacteric hemorrhage have a cancer. Whenever curetting is done, the physician should be prepared for any eventual operation as in case of taxis of an incarcerated hernia.

89. **Fibromyoma Uteri, with Thrombophlebitis.**—Paulli describes a case of fibromyoma of the uterus with thrombophlebitis alternately in legs and arms. The patient was a woman of 46. She recovered under symptomatic treatment and has been in comparative health during the year since. He believes that a developing myoma is not only a local affection, but that the organism suffers generally, possibly with a tendency to a triad of symptoms, like the triad in exophthalmic goiter, in Addison's and in Bright's disease. The triad with myoma is the tumor in the uterus, a series of nervous symptoms—neurasthenic, neuralgic or mental—and a general vascular disturbance entailing a tendency to thrombophlebitis. It is impossible to say positively which element of this triad is the primary. An anatomic heart lesion was found in 40.8 per cent. of 71 cases of myoma at the Berlin Charité as reported in 1894. Kaarsberg found pigmented degeneration of the myocardium in 4 out of 8 myoma cadavers, 2 of the deaths being due to embolism in the pulmonary artery. Kessler of Dorpat found *myofibroma of the heart* in a patient who had succumbed the seventh day after extirpation of a myoma in the fundus weighing 56 pounds. He thinks that this coincidence of myofibrosis and myoma probably occurs frequently. *In* 3 out of 5 cases

of death from embolism of the pulmonary artery observed at the hospital in Paulli's charge the patients succumbed the second week after ablation of a myomatous uterus, the fatality coming like lightning from a clear sky. Two other myoma operations were followed by death, one from secondary hemorrhage with consecutive peritonitis and one from local peritonitis with ileus. The total mortality has been 5 in 83 myoma operations during the last five years. Embolism of the pulmonary artery was not observed, except in these 3 myoma cases, in the experience of 362 laparotomies. Rosthorn had one death from embolism in 66 abdominal radical operations for myoma; Michel, 2 in 586; Burckhardt, 7 in 236; Hofmeier, 3 from embolism and 1 from "heart stroke" in 223 laparotomies for myoma, and Czempin, 2 in 82, but Engstrom had no deaths from this cause in a mortality of 5 in 100 operations. In Paulli's 3 cases of fatal embolism, slight evening temperature had been noted. Other circumstances observed indicate, he thinks, that prophylactic elevation of the foot of the bed may not prove effectual, although its importance can not be overestimated for most cases; that the heart should be stimulated before the operation with digitalis, camphor or strychnin, and that ether, and not chloroform, should be used with saline infusion of a liter a day during the first few days, with nutrient enemata. It is extremely important that the intestinal peristalsis should be promoted to prevent tympany. The rectum should be rinsed out several times a day for this purpose.

91. **Recurrent Intussusception.**—In the case related a girl of 17 had been treated for symptoms of gastric ulcer, but without improvement. A laparotomy was then undertaken on the presumptive diagnosis of gallstones, but nothing was found to indicate lithiasis. After ten days of calm the symptoms recurred, suggesting ileus this time, until the discovery of a tumor corrected the diagnosis to invagination of the small intestine. The intussusception was reduced by a laparotomy and the intestine sutured to prevent recurrence. Again the invagination recurred, this time at a higher point, reduced by a third laparotomy with resection of a loop 7 cm. long. The patient has been in good health since.

92. **Acute Staphylomycosis.**—A girl of 10 succumbed in a few days to what was apparently an acute infectious osteomyelitis. Pure cultures of the staphylococcus aureus were derived from the exudates, tissues, etc., the case being best described as an acute metastatic staphylomycosis. The clinical and autopsy findings are given in detail, with a review of the literature on the subject, especially the Russian. The general conclusions seem to be that the mortality of staphylomycosis is high and that the further necrosis of the bones is not always arrested by surgical intervention.

94. **Hemophilia.**—Bobroff had occasion to operate on a young man whose knee was swollen and painful. A similar condition had been noted a few years before after a trauma, but had spontaneously subsided. The urine was occasionally blood-stained, without known cause, and the patient's brothers suffered also from swellings in the knees and hip joints. The hemorrhage was continuous, as the knee was incised, and the blood showed no signs of coagulating. Applications of 20 per cent. ferropyrin and liq. ferri sesquichlorid internally, with ergotin, failed to arrest the bleeding, as also compression of the femoral artery for twenty-four hours. The autopsy revealed no cause for the hemorrhage. Bobroff thinks that hemophilia is due to the composition of the blood itself, probably to an abnormal proportion of cytoglobin, a product of the destruction of the red corpuscles. Another cause may be the thinness of the walls of the arteries from defective development of the musculature in the blood vessels. The elastic fibers in the skin also show a defective development in these cases and thus fail to exert the normal pressure on the capillaries, while the lumen of the arteries is unable to contract. The majority of hemophilics are slight, with light hair, white and transparent skin, blue eyes and transparent teeth, although a few cases have been published of hemophilia in the brunette and even in the negro.

95. **Hot Baths in Treatment of Epidemic Cerebrospinal Meningitis.**—Fifty-one patients out of 62 were treated with the hot baths. They were given once or twice a day for from fifteen to twenty minutes each, the water at a temperature of 32 R. (104 F.). Ice was applied to the head during the bath. The benefits were purely symptomatic, but they helped to tide the patient past the dangerous phases. The general mortality in the 62 cases was 45 per cent., but among those treated with the hot baths it was only 33 per cent. and it was zero in the 4 cases in which treatment was instituted during the first three days. One died out of 6 treated the fourth day and 6 out of 8 in which treatment was commenced the fifth day. The total mortality was thus 10 per cent. in the first four days and 39 per cent. in the 41 in which treatment could not be instituted till later. Out of 50 patients treated in another pavilion in the same hospital during the same period, but without the hot baths, 40 succumbed, a mortality of 80 per cent.

97. **Atropin in Hemoptysis.**—In the 2 cases reported nothing was able to arrest the severe hemoptysis until atropin was injected subcutaneously, when the blood rapidly disappeared from the sputa. The doses were from .0002 to .0006 gm. of atropin, repeated on six consecutive days. One patient had been ineffectually treated with innumerable measures, including ergotin, hydrastis, morphin, liq. ferri sesquichlorid and terebinthin, before atropin was tried, the rebellious hemorrhages from the lungs threatening speedy dissolution.

99. **Red Corpuscles.**—Gote asserts that very characteristic and instructive findings can be obtained by study of the proportions between the number of red corpuscles and their mass, that is, the general content of the blood in red corpuscles. He uses the hematocrit, and tabulates the findings in a large number of cases of various diseases, as also in healthy subjects. To cite a few typical cases from his tables we note in a case of croupous pneumonia that the reds numbered 4,980,000; the hemoglobin, 90; the proportional content of reds was 41; the absolute content, 8.5. In a case of chlorosis the reds numbered 2,500,000; the hemoglobin, 37; the proportional content of reds was 17, and the absolute content, 6.8. In one of myxedema the reds numbered 3,730,000; the hemoglobin, 80; the proportional content, 44, and the absolute content, 11.8, while in one case of pernicious anemia the absolute content was 16.4, with 1,212,000 reds.

SYMPTOMATOLOGY, PATHOLOGY AND TREATMENT OF CHOREIFORM MOVEMENTS.*

WILLIAM G. SPILLER, M.D.
Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania.
PHILADELPHIA.

In discussing the subject of chorea and choreiform movements, I can not hope to present to you any very startling new facts, but possibly I may be able to bring forward some observations which may not be generally known.

Lees,[1] in a discussion on chorea before the British Medical Association in 1903, remarked that chorea is often the first of a series of rheumatic attacks, and said that Batten, in 115 cases of chorea, found that whereas the percentage of previous rheumatism was stated to be only 32.2 per cent., three years later so many patients had subsequently suffered from rheumatism that the percentage rose to 43.5, and three years later still it had risen to 53.2 per cent., so that the lapse of six years had increased the percentage by 21 per cent.

Lees said further that pain and swelling of joints, which alone constitute the ordinary idea of rheumatism, are slight and infrequent in the rheumatism of childhood, and the sole but conclusive manifestation may be a subcutaneous nodule, or a small patch of erythema, or a dilated heart with a soft mitral murmur. This seems to make the diagnosis of rheumatism very comprehensive.

Lees seems inclined to believe that chorea is caused by the diplococcus of rheumatism, and that chorea is cerebral rheumatism in the great majority of cases. Indeed, he goes so far as to say that every case of chorea, however mild, ought to be looked on as presumably rheumatic, and that many a mitral stenosis in later life, with its distressful years and its premature death, might have been averted if the practitioner who attended the case of slight chorea in childhood had treated it vigorously as rheumatic.

Chiefly on the authority of G. Sée,[2] at least in France, chorea has been regarded since 1850 as of rheumatic nature, and rheumatism has been supposed to precede it, accompany it, or follow it. Numerous observations have convinced Gilles de la Tourette, Charcot, and others that this relation does not exist, and it seems to me that this relationship has been much exaggerated. In most of my cases I am unable to establish it.

Sydenham's chorea, according to Gilles de la Tourette, does not begin after puberty, and in two of his cases, in which it began at the ages of 16 and 18, respectively, menstruation had not begun. This statement, that chorea does not begin after puberty, I can not accept, and Dr. McCarthy has published some cases in refutation of it, from my service at the Polyclinic Hospital.

Chorea of pregnancy is not Sydenham's chorea, according to Gilles de la Tourette, because the latter does not appear after puberty. Chorea of pregnancy is said to be rare in France, and the cases of chorea of pregnancy are supposed to be examples of the *maladie des tics convulsifs* or of hysterical movements. This opinion is not accepted by Joffroy. He believes there is no specific infectious agent of chorea, and that various infections or auto-intoxications may cause chorea in a person with an abnormal nervous system. One of Joffroy's patients had Sydenham's chorea in early life, and in her first pregnancy the symptoms of typical chorea reappeared. One remark made by Joffroy is of especial interest, viz.: Sydenham's chorea may develop in a hysterical patient, and therefore should not be regarded as hysterical chorea. It is not improbable that many of us would have difficulty in making the proper diagnosis in some cases of this character.

Risien Russell remarks that no properly authenticated case of chorea in a third pregnancy is on record, but Copeman[3] reports a case of this character, although he is in doubt whether it really was chorea gravidarum or whether the chorea should be attributed to the more ordinary causes and the pregnancy regarded as a mere accidental complication.

Wall and Andrews[4] have discussed the causes and treatment of chorea in pregnancy, and give an account of 40 cases, occurring in 37 women, seen at the London Hospital. The cases were believed to be truly choreic in character, as the movements were indistinguishable from those of Sydenham's chorea. In 16 out of the 37 patients, there was a previous history of rheumatism; 23 out of the 37 had previously suffered from chorea. Five only of the 40 cases ended fatally, 2 spontaneous aborted, and in 3 abortion or premature labor was induced. Both patients who spontaneously aborted, and 2 of the 3 in whom labor was induced, died. The mortality reported after induction of labor in these cases, and in those of other authors, is such as to render this procedure undesirable, and it has been discontinued at the London Hospital since 1895.

It seems strange to attribute chorea to syphilis, and yet this is what Mettler[5] has done. Chorea first appeared in a patient of his when the boy, who had inherited syphilis, was 7 years of age. Four attacks occurred, about a year apart, and each attack was more severe than the previous one. All the usual *remedies for* chorea failed. Two weeks after the administration of iodid of potassium had been commenced there was a *noticeable* diminution in the movements, and in a week or two more they ceased entirely.

Sutherland[6] has recently discussed the relation of chorea to Graves' disease. All are agreed, he says, that movements of a choreiform type are sometimes manifested in Graves' disease. He quotes Gowers as saying that such movements must be regarded in some cases as a complication, although in a few cases in childhood true chorea has been supposed to exist. Dieulafoy has expressed the opinion that choreiform movements may occur in Graves' disease, but that there is no true chorea associated with Graves' disease, and that Graves' disease always occurs first.

Sutherland reports two cases to show that Graves' *disease may follow* chorea. One of the cases came under his observation during the transitional period between chorea and Graves' disease, and he had difficulty in deciding which disease the *patient* was suffering form. Choreic twitching, goiter, tachycardia, and slight staring of the eyes were the symptoms present.

Sutherland thinks these two diseases depend on a somewhat similar affection of the central nervous system, but the pathology of neither is known.

The association of chorea with epilepsy is uncommon, *according to Wollenberg,*[7] *but hysteria is often found with chorea.*

Some neurologists believe a peculiar facies exists in chorea. I have not been able to convince myself that it is common, and in expressing myself in this manner I know that I am not in accord with some whose opinion I value. The description of this choreic facies as given by B. Sachs[8] is as follows: "In advanced cases, if the tongue is protruded the mouth is opened much more widely than necessary, the eyelids and eyebrows are raised in the same effort, and then through a choreic movement of the masseters the tongue may be caught between the teeth." This, I think, is not what is meant by "*choreic facies*" by *all* who employ *this term.*

The choreiform movements of the external ocular muscles may be considered here because, according to Wollenberg, they are not uncommon. They are especially noticeable, he says, when the patient attempts to fix an object, at which time the bulbs are moved forcibly. The pupils are said to be *often* dilated, but the pupil only on the side of the choreiform movements when these are unilateral; this Wollenberg can not confirm.

A condition of spasms of the levator palpebræ that Posey[9] regarded as choreiform consisted of clonic and rhythmical contractions of these muscles so that widening of the palpebral fissures occurred about fifteen to twenty times in the minute. The contractions were entirely under the control of the will, the patient being able to initiate them or to cause them to cease when commanded to do so. The excursions of both eyes were *normal; there* was no nystagmus, and vision and accommodation were normal. The movements in Posey's case disappeared as soon as atropin was instilled *for* refractive purposes. It seems uncertain whether it would be better to class such a case as this among the tics or under chorea.

Choreic *spasm* of the vocal cords has been described as laryngeal *chorea.*

Chorea electrica I do not discuss, as most cases described under this title *probably belong* to convulsive tic.

W. Gordon[10] has found a change *in the* patellar reflex in chorea in some cases. When the patient is recumbent, if one raises the knee, allowing the heel to rest on the couch, making sure that all the muscles of the limbs are relaxed for the time being, and if then one tests the patellar reflex in the usual way, the *foot is found to rise* more or *less* smartly, but instead *of falling back immediately* it remains suspended for a variable time and then slowly sinks back to its initial position.

Eshner, in this country, *has made some observations* on the tendon reflexes in chorea, which lead him to support Gordon's views, but I have been unable to convince *myself that* there is anything characteristic in the patellar reflex in chorea.

In regard to the treatment of Sydenham's chorea, I think confinement to bed is of the greatest importance in severe cases. It is only *in this way that we can obtain quiet and freedom from* excitement in many of the cases of *chorea*, and it is especially valuable in severe *cases.*

Von Bechterew[11] seeks to put the administration of arsenic in chorea on a scientific basis. It has been demonstrated experimentally, he thinks, that arsenic causes a temporary excitability, but later a diminution of the reflexes, and affects first the nerve centers, then the nerves, and finally the muscles. He does not approve of the method recommended by Comby, viz., the administration of large doses of arsenic, and Comby himself had paralysis in one case treated in this way. Von Bechterew gives arsenic, bromid of *sodium or potassium and antipyrin* together in treating chorea, and in severe cases he adds salicylate of soda, on account of the supposed relation of chorea to rheumatism.

The administration of arsenic should be watched very carefully when the drug is given in chorea, and it is my custom, in prescribing Fowler's solution, *to order* about two fluid drams and to give directions that it is not to be renewed without permission. A number of cases of arsenical neuritis from Fowler's *solution have* been reported, and I myself have seen this occurrence. Heubner[12] speaks of a case of chorea followed by neuritis of the lower limbs, in his opinion not due to arsenic because not more than five drops had been given three times daily, and no other signs of arsenical poisoning were detected. The report of this case, though brief, reads as though Heubner *believed* that the chorea was the cause of the neuritis. Some people show idiosyncrasies toward arsenic, and I have seen herpes *zoster develop after Fowler's solution* had been given *for a week or ten days in small doses*, and it is more probable that it was the arsenic and not the chorea that caused the neuritis in Heubner's case.

R. T. Williamson[13] says that in mild cases of chorea he has seen decided improvement by treatment with five minims of peppermint water three times a day, or with very small doses of quinin, one-quarter of a grain. Therefore, while his mild cases have done well on aspirin, he hesitates to attribute the improvement to this drug. In severe and persisting cases, he believes aspirin is of distinct service in diminishing the duration of the affection. Though the drug does not immediately check the choreic movements, its administration is usually followed by distinct improvement in six or seven days after a dose of ten or fifteen grains four times a day has been reached. He has noticed steady and marked improvement following the use of aspirin in severe cases of long duration which have resisted other drugs and methods of treatment.

He usually commences with ten grains, as a powder, twice daily in children over 7 years of age, and rapidly increases up to ten or fifteen grains, according to age, four times a day. Toxic symptoms, like those caused by salicylates, do not often occur, and most children take the large doses without ill effects, but occasionally the drug causes gastric irritation or vomiting, even in doses of five grains. It is important that no alkali should be taken just after the aspirin, otherwise the drug is likely to decompose in the stomach.

Lees[1] thinks that the failure of an antirheumatic treatment in chorea may be because the doses have been too small. The dose of sodium salicylate for a child of from 6 to 10 years should be at first 10 gr., with 20 gr. of sodium bicarbonate. After two or three days the quantity should be increased to 15 gr. and 30 gr., respectively. After two or three days more it may, if necessary, be increased to 20 gr. and 40 gr. These doses should be given every two hours during the day, and every three hours during the night, 10 doses in the 24 hours. Thus the total amount of salicylate given at first is 100 gr. daily, increased to 150 gr., and finally to 200 gr.

A careful watch must be kept for any symptoms of salicylate poisoning, and especially for a peculiar, deep inspiration simulating the "air-hunger" of diabetes. If this occurs, the medicine must be immediately given up. The association of the alkali (sodium bicarbonate) seems to lessen the danger of poisoning.

The large doses of salicylate recommended by Lees did not meet the unconditional approval of the members of the British Medical Association who heard his paper.

The results of the treatment of 180 cases of chorea minor by various methods brought before the Moscow Society for the Study of Children's Diseases,[14] were as follows: The cases (86 in number) treated with arsenic were of the shortest duration, but simple rest lying down, in new surroundings (29 cases) without medicament, proved to be little inferior as a method of cure. Antipyrin (20 cases) was less useful, and bromid (47 cases) and quinin (31 cases) quite useless. The average time of recovery with the arsenical treatment was 63 days. Stress is laid on the great importance of treatment being commenced during the first three weeks of the disease.

The mortality of ordinary chorea is low, but that of chorea gravidarum has been placed by Oppenheim at about 25 per cent., and by Gowers at from 20 to 25 per cent. Death from chorea is usually through exhaustion, and, as exhaustion is not common in simple chorea, the opportunity to study the pathology of the affection is not often given.

Hudovernig examined the nervous tissues from a case of chorea.

> The patient, a girl, 16 years old, had chorea about six or seven weeks, when it terminated fatally. Scattered hemorrhages were found throughout the body. The bacteriologic examination of the blood and spinal cord was negative. The vessels of the central nervous system showed some thickening of their walls and there were new formations of vessels and perivascular round-cell infiltration. These changes were most pronounced in the medulla oblongata and pons, especially in the area of the motor tracts. The so-called chorea bodies (*Choreakörperchen*) were found near and remote from the vessels. These are round or oval, structureless formations, varying from the size of a neurogliar cell to ten times this size. They were found especially numerous in the pyramidal tracts. A slight leptomeningitis and ependymitis were observed. The nerve cells of the cerebral cortex showed granular change of the chromophilic elements.

Hudovernig thinks that the toxic and infectious nature of chorea is generally accepted, and he attributes this theory to Leube. Some, however, do not believe that all cases of chorea are of this nature, but especially so are the postpuerperal or postrheumatic cases. This opinion has been strengthened by the finding of diplococci or staphylococci in cases of chorea (Pianese, Dana, H. Meyer, Geddes and Clinch).

Hudovernig has not found any case of chorea with a chemical examination of the blood reported, but he finds that encephalitis and meningitis are common in chorea. In his case the alteration of the nerve cells of the cerebral cortex was intense and in all parts of the cortex, and this indicated that all parts of the brain were exposed to the injurious substance.

The only other case of chorea in which the method of Nissl was employed that Hudovernig knows of is the case of Silvestrini and Daddi. These investigators found rounding off of the pyramidal cells, chromatolysis and pigment formation within the cells.

Elischer seems to have been the first to find the "chorea bodies" in the brain in chorea, although this author did not attribute much importance to them. He found these bodies in rows or groups, having a faintly concentric arrangement, and always near blood vessels. Flechsig found similar bodies in the globus pallidus and in the lymph sheaths in four cases of chorea. Jakowenko, in six cases of chorea gravis, found these bodies in the lenticular nucleus, and in one case also in the optic thalamus and caudate nucleus. All six patients had also acute delirium.

Jakowenko studied the brain in a case of acute delirium without chorea and found some similar bodies, with, however, a different chemical reaction. Laufenauer also found these bodies in the brain from five cases of chorea; they were chiefly in the basal ganglia, but were found in the entire central nervous system. Wollenberg found these bodies in cases not of chorea as well as in chorea, and he concludes that in some cases of chorea, simple chorea, as well as chorea with delirium, they are found in the globus pallidus; they are not characteristic of chorea, as they may occur in other diseases. These bodies are probably caused by calcification of an organic ground substance (*Grundsubstanz*), concerning the nature of which a positive opinion can not be formed. Von Bechterew and Dana also have found the chorea bodies in chorea, but they are not present in every case of chorea.

---

[13] Williamson: Lancet, Aug. 22, 1903, p. 326.

[14] Abstract in Epitome of Current Medical Literature, British Med. Jour., vol. ii, 1903, p. 27.

Hudovernig[15] believes that the lesions of chorea minor are not confined to the same part of the brain in every case, although the basal ganglia are often affected; but that in every case the motor tracts are irritated in some part of their course.

His conclusions are: Chorea minor is an infectious disease and the infection is hematogenous. In the mild cases the infection causes a disturbance of nutrition, but in more severe cases it causes changes in the blood vessels and formation of colloid bodies, the latter being an evidence of a severe form of the disease. "Chorea bodies" are characteristic of chorea, although they are not found in every case. Choreiform movements are always the expression of direct or indirect irritation of the pyramidal tracts at some part of their course.

Hudovernig found that the "chorea bodies" have a great affinity for hematoxylin, stain pale red with carmin, remain unstained by the Nissl method, and do not give the amyloid reaction. He does not discuss the resemblance of these bodies to the so-called amyloid bodies, but from his description and drawings they seem to resemble them closely.

In examining some sections from a case of Sydenham's chorea, prepared by Dr. J. H. W. Rhein, we found small, recent hemorrhages in the cerebral cortex.

Dana,[16] in a case of Sydenham's chorea, found chronic leptomeningitis of the convexity of the brain, hyaline bodies in the brain cortex, slight meningitis of the upper part of the spinal cord, slight meningo-encephalitis, and diplococci in the proliferating tissue between the meninges and the brain.

In a case of chorea gravis, Geddes and Clinch[17] found great congestion of the meninges, which had resulted in severe hemorrhages. The basal ganglia showed no congestion to the naked eye. Intense degeneration of cells and of the myelin sheaths in the brain was found, but the appearances were regarded as a result, rather than as a cause, of the symptoms, and resembled the findings obtained in animals deprived of sleep. Some of the blood vessels were much thickened.

A case in which I have been able to make a microscopic examination of the brain is as follows: The patient, a girl, 16 years old, had had chorea for about five weeks. She had inframammary tenderness and was unable to talk coherently. A systolic murmur was heard at the apex. She had violent choreiform movements of the entire body, including the face. The head was tossed from side to side, the arms and legs were violently moved. At times she was comparatively quiet, while at other times the whole body was tossed violently from side to side, the head and limbs striking against the side of the bed. These violent attacks did not occur at regular intervals and were increased by observation.

Family History.—The family was neurotic, and the father had been in an insane asylum. About six weeks before the girl came to the hospital her household goods had been sold by the sheriff, and she had been much worried by this.

Present Illness.—She had had chorea only about ten days before admission (May 30, 1901). It began with twitching of the muscles on one side of the body, but within a few days the other side became involved.

Progress of Disease.—While in the hospital the girl had delusions. She believed her mother and uncle had visited her, although they had not. The movements were absent during sleep. Later she became unconscious of her surroundings, and the movements became exceedingly violent.

She died May 31, 1901. The nurse found the patient dead, although five minutes previously she had been sleeping and seemed better. Directly after death the temperature was 109.

Necropsy.—June 1, 1901. Pathologist, Dr. Pearce. The pathologic findings were chronic mitral endocarditis, acute parenchymatous nephritis, fatty degeneration of liver, edema and congestion of lungs, hypoplasia of heart and aorta.

The nerve cells of the paracentral lobules stained very diffusely with thionin and a small round cell infiltration was found about the small vessels of the cortex, but not within the pia. The microscopical examination has not been completed.

Huntingdon's chorea is regarded now by most physicians as distinct from the Sydenham form, although Charcot held a different opinion.

It has been pointed out that intentional movements sometimes diminish the jerkings of Huntingdon's chorea, whereas they do not in Sydenham's chorea (Ewald, Peretti, Lannois, and others); and that the muscles of the eyeball are not implicated in Huntingdon's chorea, whereas they are in Sydenham's form. The tendon reflexes often have been found exaggerated in Huntingdon's chorea (Biernacki, v. Sölder, Wollenberg).

In many cases of Huntingdon's chorea the neuroglia has been found proliferated and the gyri atrophied, and a resemblance has been pointed out to the alteration of paretic dementia, although in the latter the frontal lobe is chiefly affected and in the former the motor area.

In a case of Huntingdon's chorea examined by Stier, the brain was atrophied, the small, round cells were more numerous in the second and third cortical layers, especially in the motor regions, the neuroglia cells also were more numerous, the tangential fibers were diminished in number, and the small, pyramidal cells of the second and third cortical layers presented degeneration and diminution in number. He was unable to find the accumulation of small, round cells especially about the vessels, and the alteration of the membranes described by others. He says that, in all cases, an increase of the glia cells, or of small, round cells, was found. In some cases hemorrhages have been observed. In most cases the cortical motor region has been affected, and in all cases the nerve cells have been diseased, even though the alteration was slight in some cases. The cells of Betz escape, or are little degenerated. In most cases the walls of the vessels have been thickened.

Stier[18] goes so far as to say that no one in the last twenty years has doubted that the cerebral cortex is the seat of Huntingdon's chorea.

The disease begins late in life, with proliferation of the neuroglia in the motor centers, either diffusely or in areas, and is found especially in the second and third cortical layers; simultaneously, the vessels become diseased, and cellular infiltration into the pericvascular and pericellular spaces, and sometimes hemorrhages occur. The small and medium size ganglion cells become diseased, whereas the large nerve cells remain intact.

In a case of Huntingdon's chorea that I examined small collections of round nuclei were seen about some of the capillaries of the cortex of the paracentral lobule, and also elsewhere in the cortex not about the vessels.

It is difficult to form a judgment concerning the cells of Betz, as the sections were not stained by Nissl's method, but some of them were smaller than normal and contained eccentric nuclei.

[18] E. Stier: Arch. für Psych., vol. xxxvii, No. 1, p. 62.

The condition of postapoplectic hemihypertonia, so far as I know, has been reported in this country only by me and later in a case from my clinic described by McCarthy. This form of spasm is very different from athetosis. It is of tonic character, affecting one side of the body, is associated with a little weakness, but not with contractures, develops after an apoplectic insult, and probably is due to irritation of the motor fibers at some point below the motor cortex.

Von Bechterew deserves the credit for clearly recognizing and first describing the condition, and has spoken of it as hemitonia apoplectica, but inasmuch as it affects only one side of the body and develops after an apoplectic attack, I have suggested that it might be called more appropriately hemihypertonia postapoplectica. The disorder is such a remarkable one that I cite a portion of the report of my case.[19]

The patient is a well-developed woman with no distinct atrophy of any of the muscles. Her gait is a little spastic on account of the spastic condition of the right lower limb, but she does not swing this limb from the hip, as is so commonly seen in hemiplegia, nor does she drag it. Her station is good. The right knee-jerk is restrained on account of the spasticity of the lower limb; the left is normal. The toes of the right foot are usually flexed, but the condition is not one of contracture; it is one of tonic spasm and every few moments the degree of tonicity varies. No athetoid movements are seen in the toes. The right foot appears to be about the same size as the left.

When the right hand is at rest in her lap it is often slightly flexed at the wrist, and the fingers slightly flexed at all the articulations. The hand may remain in this position a long time, while the limb is at rest, without any evidence of athetoid movement. If she attempts to elevate the right upper limb from the shoulder she accomplishes the movement without difficulty, but the right wrist becomes strongly flexed, the hand may be drawn around so that the back of the hand is turned away from the body of the patient, or at other times the palm may be turned away from her body. The condition is one of tonic spasm, and the spasms vary greatly in degree from time to time, and are increased by excitement. When she was told to make some movement with her left hand, such as removing her shoe, the position of the right hand and fingers changed from one of flexion to one of extension; the fingers were fully extended, but still in tonic spasm. At no time did this condition of great hypertonicity disappear from the right hand: it varied merely in degree, and the position of the hand changed according as the spasm predominated in one group of muscles or another, but the flexors were always most involved. It was impossible at any time to detect any athetoid movement. She is able to carry objects suspended from her right hand, and can perform such work as wringing clothes, the powerful grasp of the right hand enabling her to hold the clothes firmly. She can not venture to hold anything breakable with the right hand, as the spasm may relax and the object fall to the floor. When quiet and unobserved the spasm in the right hand is much lessened in intensity, and she may be able to use the hand to a surprising extent, according to the statement of her sister. At times the hand is forcibly flexed at the wrist, the fingers are flexed, and the thumb is firmly held between the middle and ring fingers; the hand may then be rotated towards the right or left; at other times the hand is rotated at the wrist and the fingers are partially extended; at other times the hand is extended at the wrist, the thumb flexed into the palm and the fingers firmly flexed on the thumb. At no time has the spasm of the extensors predominated over that of the flexors.

Involuntary movements in the paralyzed side, truly choreiform in character, occurring after hemiplegia in the adult must be very rare.

Bonhoeffer remarks that Charcot called attention to the frequent association of hemianesthesia with posthemiplegic chorea, and concluded that in front of the *carrefour sensitif* is a bundle of fibers, a lesion of which causes hemichorea. Gowers thought that a lesion of the optic thalamus is followed by chorea. Kahler and Pick believed that the choreiform movements are caused by irritation of the pyramidal tract. In Bonhoeffer's case of chorea resulting from carcinoma in the superior cerebellar peduncles the movements were chiefly unilateral, but the case differs from most of those of hemichorea reported in the absence of hemiplegia or hemiparesis and of sensory disturbances.

In some cases of hemichorea the movements at times are more choreiform, at other times more athetotic.

The cases of choreiform movements resulting from lesions of the cerebral cortex collected by Bonhoeffer are not very convincing. In the cases cited by him in which hemichorea occurred from lesions below the optic thalamus the lesions involved the nucleus ruber or superior cerebellar peduncles. Lesions in the lower part of the medulla oblongata or in the spinal cord, without associated cerebral lesions, apparently never cause choreiform movements, and this is against Kahler and Pick's theory. Lesions in front of the knee of the internal capsule and in front of the projection fibers of the central gyri, do not seem to cause choreiform movements.

Hemiplegia is common, hemichorea is rare: it is hard to understand why the latter should be so if Kahler and Pick's theory be correct.

Lesions of the cerebellum, Bonhoeffer[20] finds, cause choreiform movements, and he says that in all cases of chorea caused by lesions the fibers of the superior cerebellar peduncles have been implicated.

CONVULSIVE TIC.*

HUGH T. PATRICK, M.D.
CHICAGO.

From the great and rather confused mass of affections characterized by excess or perversion of movement, one group or sub-group is coming to be pretty well defined: a variety of hyperkinesia which might well be called simply tic if it were not for the occasional use of this word as a contraction of *tic douloureux,* painful tic, to designate trifacial neuralgia. This being the case, it seems best to call the tic of movement convulsive tic. I believe that ultimately the qualifying word convulsive will be dropped and that the term tic will come to mean motor tic exclusively. In this paper I shall often so use it.

Convulsive tic embraces movements varying as regards location, extent, violence, amplitude, frequence and duration. It may affect any part of the voluntary muscular system, and in the cases of extreme severity, called by Gilles de la Tourette *maladie des tics*—the disease of tics—the entire body is affected by peculiar, sudden, more or less violent, intempestive, malapropos gestures, grimaces, contortions.

---

[20] Bonhoeffer: Monatsschrift für Psychiatrie und Neurologie, vol. i, p. 6.

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Although the tic group embraces such a great variety of movements, and although now and again an individual case may present great difficulties of diagnosis, and show that here, as elsewhere, the dividing line may be hard to draw, none the less are the great traits of tic characteristic and the diagnosis generally easy.

I shall attempt no definition of tic, as doubtless it would be too faulty to be useful. A brief description of the disease, with a few comments, will serve the present purpose.

In the main, convulsive tic may be said to be a habit spasm, but it is more than a habit, less than a spasm. Strictly speaking, it is no spasm at all. It is a movement based on an uncontrolled and, except for a brief space, uncontrollable impulsion. It is the motor impersonation of an imperative inclination, the motor gratification of an imperative appetite. To state it another way, the motor phenomena are the objective manifestation of tic; they do not constitute the disease. While the movements of tic are for the greater part fairly beyond the control of the patient, they are not entirely so, and in this they are trenchantly separated from true spasm. In its inception I believe that a tic is always voluntary. With time it becomes more and more automatic, passes more and more into the subconscious, more and more beyond the will, but a volitional element always remains. In other words, tic is of psychic origin. When Brissaud called spasmodic torticollis, which is a variety of tic, "mental torticollis," he coined an illuminating term.

The expression convulsive tic implies a motor malady. This is only half of the truth, and, if one may be pardoned a hibernianism, the lesser half. In nearly every case of tic the original cause is sensory. Not only that; very often it is the sensory element which perpetuates the spasmodic movement and makes it hard to cure. Even though each movement be not the direct response to a sensation, one is pretty sure to find that the execution of the movement gives the patient a certain sense of relief or satisfaction, which shows a sensory foundation for the trouble.

Let me illustrate. In crossing the great American desert a man suffers greatly from alkali dust. It irritates his eyes, he develops some conjunctivitis and blinks constantly. Having reached the coast, the palpebral spasm continues even after the conjunctivitis is cured. The constantly recurring spasm irritates the conjunctiva, the sensation from the conjunctiva starts the spasm, and thus is developed a most rebellious habit spasm, blepharospasm, tic.

In one of my clinics I saw an exactly analogous case caused by a workman digging a ditch in dry sand during windy weather. The vicious sequence was as follows: Repeated puffs of sand in the eyes, repeated violent closing of the lids, repetition of this closure after work, when there was no sand in the eyes, still some slight discomfort, enough to start the impulse to close the lids, perpetuation of an uncontrollable impulse to blink the lids tightly together.

A boy has an ill-fitting collar or a coat too tight in the armhole. This begets a twisting drawing of the neck, with tilting of the chin or a writhing shrug of the shoulder. The collar is removed, the armhole enlarged, but the abnormal movement continues.

A child has nasal catarrh which causes a sense of discomfort about the nostrils. In consequence there is a twitching and drawing of the nose and lips. The catarrh is cured, the movements remain.

Because of an ordinary "stiff neck" a man repeatedly turns his head in a certain direction. Putting a little strain on certain muscles affords a certain degree or sort of relief. Or, in consequence of the sore muscles, he carries the head in a constrained, unnatural position. After recovery of the myalgia the patient continues to carry the head to one side or to repeatedly twist it in a certain direction. This tendency becomes more than a habit. It is a veritable obsession, not to be resisted, causes a sense of acute dissatisfaction when resisted and when yielded to affords a certain sense of relief. This is tic.

A number of times I have known some peculiar motion incidental to the patient's occupation to develop into a tic. For instance, within a few days I have examined a waiter with spasmodic torticollis. His affection draws the head over and tilts the chin into just the attitude he assumes in carrying a tray, heavy with dishes. However, in such cases I think the discomfort of fatigue or strain has much more to do with the genesis of tic than does the mere repetition of certain muscular contractions.

In a few instances, especially in children, the inception of a tic lies in imitation. Afterward the sense of relief attained by executing the movement or the sensory result of the movement itself serves to perpetuate it. In other cases it is simply impossible to discover what the exciting cause has been. It has been so slight or so transient, or both, as to escape the memory of the patient if, indeed, he was conscious of it at the time.

A most important element in the genesis of tic, and equally a matter of paramount importance in prognosis and treatment, is the psychic state or mental constitution of the patient. Tens of thousands of children have nasal catarrh and ill-fitting clothes, thousands of adults have rheumatic stiffness about the neck and shoulders, very few acquire tic. At present hundreds of thousands of women are wearing large hats so poorly balanced on the head as to cause a feeling of insecurity or slight discomfort. Any one who will take the trouble to look may see many of these women give the head a little jerk or shake because of the sensations produced by this maladjusted headgear. Of these many, assuredly a few will develop a tic. I have seen it—a tic which will continue when fashion shall have returned to the compact close-fitting toque.

But why, of the very many, do only some twitch the head? Because they are more sensitive to impressions and more readily translate a sensation into motion. Of the relatively few who jerk, why will only very few, indeed, develop a jerk neurosis? Simply because of a still higher degree of hypersensitiveness and nervous instability. The subjects of tic are too sensitive, too impressionable, their sensori-motor mechanism is too glib and they lack in instinctive as well as voluntary inhibition; else they would not have tic. Of this I shall have something more to say in connection with prognosis and treatment.

CHARACTERISTICS OF THE MOVEMENTS.

Now, as to the characteristics of the movements themselves, it may first be said that they represent natural acts or that they are imitations of natural acts.

I had almost said physiologic acts, but the term is too strong. It may be physiologic to pinch the eyelids tightly together when a foreign body is blown into the eye, but to wriggle the shoulder about because the sleeve is too tight, to rotate and twist the head about because of a discomfort in the neck, or to make grimaces because of dessicated mucus within the nostrils is scarcely within the bounds of physiology. Still these acts are hardly pathologic. They are strictly logical, they are co-ordinate, the legitimate result of a given cause. If the source of irritation having been removed the movement is continued, it is unnatural, pathologic. If, in addition, it grows more imperative, can not be resisted, becomes automatic or subconscious and carries with it a sense of relief, or at least relief as compared with the tension and discomfort of resistance, it constitutes a tic.

But the movement itself remains the same. The same muscles act in the same way. The movement is purposive. It is an action perfectly adapted to an imaginary end or to an object which has disappeared. It shows the same co-ordination, generally the same duration, but may become more tempestuous. Such a movement is in marked contrast to the inco-ordinate purposeless jerkings and writhings of chorea, the vermicular twistings of athetosis, the rhythmic oscillations of hysteria, the fascicular twitching of paramyoclonus and the anatomically localized true spasm.

The movements of a tic are always a repetition of the same act. This statement needs some explanation: *a.* The movements may vary in degree, some of them being more or less abortive, others more or less complete *b.* As time passes they incline to become more intense or violent. *c.* A tic also tends to spread to adjoining muscles or muscular groups and to add to itself correlated physiologic acts. A tic of the nose is apt to soon involve the lips and adjoining facial muscles. When sounds of snuffing or sniffling are produced, pharyngeal and laryngeal sounds may be expected, if the disease continues. *d.* In the *maladie des tics,* in which the whole body is affected, the abnormal movement may be now of this part, now of that. A grimace is followed by a shrug, that by a grunting sound and this by a kick.

With these qualifications the dictum beginning the foregoing paragraph holds good; that is, a tic is the repetition of the same sort of thing in the same place. This, again, is in marked contrast to chorea in which no two movements are exactly alike.

The third trait of tic to which I beg to call attention is one already mentioned; namely, it can be voluntarily restrained to some extent, and in many cases can be quite controlled for a time by some maneuver which the patient has instinctively or deliberately hit on. These tricks of control are oftenest seen in cases of spasmodic torticollis. Frequently they are done unconsciously by the patient, but may nearly always be found. A few examples will illustrate:

An orthopedist friend was exhibiting to a medical society an apparatus for torticollis, and, incidentally, a patient. I asked the latter in what way he could control his spasm. He said "in no way:" that he couldn't control it at all. Even as he spoke he passed his right hand to the back of his head and grasped the occipital region in the hollow of his hand. With this mere semblance of restraint, the drawing and rotation of the head ceased at once. A patient of my own, when asked to undress for the first examination, stood with his head propped against the edge of an open door, as he slowly got out of his clothes. I asked him why he did that. He replied that it was the only way of steadying his head while he was on his feet with both hands occupied.

Many of these patients are comparatively comfortable while seated in a high-backed chair, where the head can be rested. With numerous others a favorite posture is with the chin resting in the crotch between thumb and flexed second finger, while the index is extended upward along the cheek. One of my patients had not for years appeared on the street without a certain straight-handled umbrella. This he held perpendicularly, with the handle alongside his nose, and with this mere trick of restraint was able to go about with his head relatively straight and quiet. In a remarkable lecture, Brissaud[1] has given some interesting examples of the restraining action of the touch of a finger, etc., and Meige and Feindel[2] quote many more; but one of my own cases showed the potency of an idea in restraining tic to a degree that, I think, must be unique.

The patient was a man of 41 years, who had been suffering for eight months with spasmodic torticollis, which had become very bad. His head rotated to the right. During my examination, as one of the strong contractions came on, I asked him to turn his head to the left. He said he could not possibly do so during the spasm. I told him that he could, and, opening a blade of my pocket knife, said I would immediately demonstrate that I was right. He at once saw that I meant to prick the side of his face to make him turn it the other way, and assured me that that was not necessary; that he had an easier and more comfortable way. He extended his right arm to the right, crooked the elbow and wrist so as to point the extended index finger at his face, just as he would have held a pistol to shoot off the end of his nose, and then moved this hand rather quickly toward the nose. As he did so the head rotated toward the left, as if moved by an invisible power, and assumed a normal position. At no time was the finger nearer than eight inches from the face.

In accord with the foregoing is the fact that tic does not derange voluntary movements. A man with a tic, never so severe, of the right arm and shoulder shows nothing of it in his writing. The tic does not catch him unawares. When the impulsion to tic can no longer be bridled, he takes pen from paper, executes his tic, and then resumes writing. I know a successful artist who is afflicted with a bad tic of the head and arms. It delays his work more or less, but never deflects stroke of pencil or touch of brush. This alternation of constraint and compliance is something very striking. After unusually prolonged or complete voluntary control of the abnormal movements, especially if the patient can escape observation for a few moments, he will often recompense himself by a perfect debauch of tics until the craving is satisfied.

Tic is diminished by rest, quiet, preoccupation or mental diversion. On the other hand, it is made worse by self-consciousness, observation by others, excitement and other emotional states, pain and fatigue. During sleep it disappears entirely.

PROGNOSIS.

The prognosis of convulsive tic conforms to no rule. In children, ordinarily it is good. In fact, most of these little patients recover without treatment or with treatment for chorea, which amounts to no treatment at all. Nevertheless, a tic begun in childhood may continue through life. Most frequently when it begins at an early age and continues for many years, the location changes. Many of my cases have shown this. A tic about the nose ceases, or nearly so, to be succeeded by a lifting of the eyebrows. This passes away, the patient becomes possessed of an impulsion to shrug a shoulder, and this is followed by a sniffing or hemming tic. Finally, after years of "ticing," such a patient's tendency may crystallize into one permanent set of movements that continue to the end or until the degenerative age of dullness and slow reaction.

---

[1] Leçons sur les maladies nerveuses, 1895, p. 502.
[2] Les Tics et Leur Traitement, Paris, 1902.

In adults, tic is a most rebellious disease. The more severe and chronic cases are seldom cured. The slighter ones yield to treatment fairly well. Occasionally the trouble disappears of itself or is simply controlled by the efforts of the patient. Of the tics more difficult to cure, spasmodic torticollis is the most frequent. In spite of a few favorable reports, Gilles de la Tourette's disease may be said to be incurable.

To consider the why and wherefore of this sinister outlook would involve a discussion of the nature, etiology and genesis of the affection. Such a discussion is not for a short paper, but I may mention two elements that bear on the prognosis. First, the nature of the patient; second, the nature of the disorder.

The patient is generally a nervous, impatient, hypersensitive individual in unstable equilibrium. Small things upset him and every upsetting makes him the more unstable. Mentally, he is unsatisfactory. His emotions are uncontrolled and he confuses desire with judgment. Ignorant of premises, he forms opinions none the less positive because groundless. The victim of impulse, appetite and feelings, he never knows what he is going to do or be.*

The disease has been called a psychomotor neurosis. I would prefer to call it a sensori-psychomotor derangement. Sensation is the beginning. This acts as a psychic excitant and the psychic state, or maybe the sensation and this together, as a motor excitant. The movement gives rise to sensation, which again starts the endless chain. Each step in the order of events incites the next, so that it seems as natural for a tic to continue as for the planets to pursue their orbits.

To these two elemental factors of a bad prognosis, I might add a third, applicable to cases in children: unstable, unreasonable parents. A child with tic is likely to be the spoiled child of spoiled parents. To an unfortunate heritage is added unwise rearing. What began as a natural, but unnecessary, movement is allowed to become a habit and then an infirmity.

In connection with the prognosis I may note that I knew one patient with severe generalized tic who committed suicide rather than longer endure his malady. Another patient, a lady with spasmodic torticollis which had not responded to rather prolonged treatment, died suddenly under circumstances strongly indicative of suicide. She had assured me that if she were not cured within a certain time, she would terminate her life, and she died at the end of the appointed time.

TREATMENT.

Given the above dubious prognosis, the question of treatment is somewhat embarrassing. It is the more so because my own efforts to cure severe tic, notably spasmodic torticollis, have been anything but satisfactory.

In children, if directions can be and will be carried out, most cases yield promptly. In accordance with what I have said concerning the cause of the affection, I begin with a careful search for any sensory state which would naturally cause the movement exhibited by the patient. About the face, the eyes and nose are the most fruitful sources of trouble, but all parts must be scrutinized. About the neck and shoulders, rheumatism is a frequent cause. Skin eruptions, ill-fitting clothing, traumatism are not unusual. Having removed the sensory excitant, I ordinarily adopt one of two methods: hypnotism or systematic stimulation of inhibition. The latter means constantly reminding the child of his tic, together with a judicious combination of penalty and reward. For successful effort he is recompensed, for letting go of himself he is punished, but both must be arranged so as to keep consciousness vigilant. That is, every single movement is to be accounted for. Rewards and penalties alike must be frequent and small. I have never known whipping a child to cure a tic. Many times I have known it to fail. But simply to prick the patient with a pin every time he made a grimace or jerked his head I have known to be perfectly effective.

To rephrase it: the tic is the result of a strong but subconscious impulse. It is followed by a certain amount of satisfaction or relief, likewise scarcely appreciated. It is, if you please, the instinctive gratification of an unconscious craving. Now, if with each and every gratification there occurs a disagreeable or painful impression, this soon impresses itself on consciousness and coincident with the impulse to tic comes the impulse to forbear. As soon as the latter impulse regularly exceeds the former, the tic ceases. When the former ceases to be, the tic is cured.

This method I prefer to hypnotism if parents or attendants will carry it out. It is the more natural and, I think, the more permanently effective. Sometimes it is easier and quicker to hypnotize. Under some circumstances it is about the only available way. Most children may be hypnotized, and if the sittings can be sufficiently frequent, a tic may be expected to improve rapidly.

As before stated, treatment of adults is unsatisfactory. To enumerate the almost countless forms of tic and then consider all the means of controlling them would require a treatise as tedious as it would be lengthy.

Principles of treatment must be the same for the adult as for the child. The material to work on, however, is vastly different. Putting aside the mild tics which are scarcely more than habits, stereotypes, as the French call them, excluding the more complex syndrome of Gilles de la Tourette and taking spasmodic torticollis as a type of the more severe and refractory tic of the adult, I beg to submit a few remarks on its treatment. Before doing so, however, I should state that while spasmodic torticollis conforms to all of the essential standards of tic, it seems in some respects to be in a class by itself. It is the only tic which, with any frequency, is consistently tonic. Sometimes the nervous instability, upon which I have laid much stress, is scarcely apparent. The discomfort may amount to decided pain: very rare in other tics. Finally, this form of tic, after persisting for many years, may gradually take on characters suggestive of degenerative disease of the nervous system. I[3] have now under observation a man who many years ago began to have what was apparently an ordinary spasmodic torticollis. Indeed, an eminent surgeon operated on him for this affection. He has gradually grown worse until now nearly all the muscles of the body are involved in irregular clonic and tonic contractions. He walks but poorly, has quite imperfect use of the arms, and the trunk is distorted with what appear to be permanent organic deformities.

---

* It seems proper to add that this impressionability and emotional instability may not be very apparent and their presence sincerely denied by patient and friends. More than once I have been unable to uncover the neurotic tendency in one interview. Repeated observation has never failed to reveal it.

Operative treatment has been notoriously unsatisfactory. Indeed, torticollis is the only tic for which operation has been done with any frequency. Based on the erroneous idea that spasmodic wry neck is a local spasm and that paralysis of the contracting muscles will render the movement impossible, the procedure was, from the first, doomed to failure. The affection is a physiologic, not an anatomic hyperkinesia, and no operation yet devised can abolish movements of the head when the patient, consciously or unconsciously, chooses to make them. About two years ago I saw a case of progressive muscular atrophy in which both sternomastoids and both trapezii, as well as some other neck muscles, had quite disappeared. There was no normal movement of the head or neck which the patient could not execute.

This is not to say that operation has never succeeded. It has. Personally, I have never seen a success, but I have heard of one or two and some are on record. When operation succeeds it is not by way of paralysis but because the pain, fixation, and psychic impression inseparable from the operation serve to break up the habit. Practically the same conditions may be attained by milder means without the danger of aggravating the trouble. That operation makes these cases worse is no uncommon experience.

I have known a typical tic of the neck muscles to be caused *de novo* by operation on the spinal accessory nerve. Nearly two years ago a gentleman of 36 years was referred to me for an opinion. The case was a sufficiently typical one of congenital cerebral quadriplegia (Little's disease) of the very mildest type and without mental impairment. As in so many of these cases, there was some excess of associated movement and considerable, though not severe, irregular rolling, jerking movement of the head and neck. This was increased by conversation, by active use of the hands, and by excitement. It constituted no disability, was somewhat annoying, but hurt the patient's vanity more than anything else. The question of operation had arisen. It was easy to see that the sternomastoid and upper trapezius on one side were the muscles most active in causing the movements, and I told the patient that paralyzing these muscles might make the movement somewhat less noticeable. The operation was well done, but it served only to add a new trouble to the old. The discomfort of the wound, together with the anxiety and uncertainty regarding the result, or some other effect, were sufficient to start a spasmodic torticollis in an individual already nervous, impressionable and unstable. The new disorder showed all of the typical characteristics of "mental torticollis," or tic.

My own idea of the surgical treatment of spasmodic torticollis would be section of the sensory roots of the cervical spinal nerves. All sensation from the affected area having been cut off, I believe that the so-called "spasm," the result of sensory stimuli, could easily be controlled. Of course, this operation is too serious to be recommended for a disease not dangerous to life.

So far as I can ascertain, the mechanical or orthopedic treatment of spasmodic torticollis has been no more successful than the operative. I know of no case thus cured, although I have learned of a very few that have been improved.

My own attempts have been along various lines. Some years ago injections of atropin into the affected muscles were advised. I tried them, and they made my patients worse. The muscular soreness produced by the injection simply increased the local discomfort and the patient's self-consciousness. The ordinary sedatives I have tried, and they have constantly failed in my hands, as in others. A few years ago, in a discussion before the American Neurological Association, conium was highly spoken of. In my next case I gave it a faithful trial. At first there was some relief, but this was transient, and subsequent doses, carried to the toxic limit, accomplished nothing.

In one bad case I tried the opium-bromid treatment, as advised by Flechsig for epilepsy. It was of no avail.[4] During the course of opium the patient was not uncomfortable. When I changed to the bromid he did not take it well, and was soon as bad as ever. Once I nearly cured a bad case of many years standing by means of hypnotism. For several weeks the case progressed in a way most satisfactory to me and wonderful to the patient. Then, contrary to my strict injunctions, he had a long interview with a relative. This made him more nervous, which I at once noticed and finally elicited the cause. My reprimand was resented. Because of his frame of mind, the following sitting was less successful than the preceding ones. The lack of success engendered lack of confidence, and the next sitting accomplished nothing. Disappointment, regret, loss of hope, despair, followed in turn and the patient returned to his home nearly as bad as when he came.

Two years ago I saw, in London, a case of Bastian's practically, not absolutely, cured by keeping the patient asleep most of the time for several weeks. I came home and tried the method on an old and very rebellious case. The result was gratifying. At the end of the sleep period the patient was very much better and then, under the exercises to be mentioned presently, he continued to improve. He returned to work with only a trace of his trouble, but a perfect recovery was not obtained.

The very next time I used this treatment, dismal failure was the result. Even when the patient was asleep 18 hours out of the 24, during waking moments the spasm asserted itself with a vengeance. And, as the effect of the drugs wore off, the trouble resumed its wonted severity.

My friend, Dr. Singer, formerly of London, now of Omaha, recently informed me that in two cases he had had excellent results from suspension. I immediately tried it, but before the treatment was well under way, the patient got homesick and left the hospital.

Meige and Feindel have elaborated a system of exercises advocated by Brissaud and have treated a great many cases in this way. Their results have been good, the method is rational and constitutes a real addition to our means of combating a most troublesome disorder. To go into detail would require a separate paper. A full description will be found in the excellent and exhaustive treatise by these gentlemen.[5] Stated simply, the system is one of dynamic and static exercises, gradually teaching the patient to move and hold his head properly. This is no easy task. Great patience, persistence, tact and good judgment on the part of the physician; patience, persistence, courage and confidence on the part of the patient are the requisites for success. While the advocates of the treatment are loud in its praises, not to say enthusiastic in their propaganda, their statements will be found to contain sundry qualifying terms and conservative cautions. I must confess that their reports seem to lack definite statement of complete cures.

---

[3] Revue Neurologique, April 30, 1902, p. 351. For a remarkable and wonderfully full discussion of tic, see Revue Neurologique, Aug. 31, 1902, p. 766, et seq.

[4] I have lately learned that the same treatment has been advised by others.

With this, as with all other methods of treating spasmodic torticollis, the great drawback is the patient himself. As I have before indicated, he is generally a neuropath *par excellence*. He is hypersensitive, too impressionable, erratic, poorly balanced. His enthusiasm is transient, his faith evanescent, his disappointment overwhelming, his desires paramount. Although he may be intellectually brilliant, he is mentally puerile; he can not control himself and is most difficult to control. Just when the treatment, whatever it may be, is running smoothly, some whim, feeling, emotion, desire or opinion of the patient intervenes to derange the whole plan and withhold success. Within an hour such a patient's whole mental attitude may be quite reversed. From hearty co-operation with his physician he changes to skepticism, distrust, mutiny, perhaps as quickly to return to allegiance and obedience.

My present opinion is that the soporific treatment, followed by the educational exercises of Brissaud, will be found effective in more cases than any other method of treatment. By means of veronal, trional, chloral and bromid, the drug to be changed every few days, the patient is kept asleep nearly all of the time for three or four weeks. As the waking time increases, he is shown how to practice moving the head slowly, rhythmically and normally in every direction. He is also to practice holding it quietly in any given position. At first the exercises must be executed under supervision. Later he can manage them himself, preferably with the aid of a mirror.

HYSTERICAL MOVEMENTS.[*]

HOWELL T. PERSHING, M.D.

DENVER, COLO.

I understand that in assigning me the subject of hysterical movements it was not intended to include the phenomena of the ordinary hysterical convulsion, but rather to bring up for discussion such motions of hysterical origin as may best be considered in comparison with chorea and convulsive tic. Thus restricted the subject is a very important but very difficult one. I would not undertake to say anything about it had it not been assigned to me.

Certain general principles are applicable to all such movements, and to avoid needless repetition they may first be briefly stated.

The possibility of organic disease must always be considered and the signs that would reveal it carefully looked for in the examination; only when it has been excluded are we safe in attempting to discriminate among the functional diseases.

Hysteria being a functional disease of the cortex, the motions caused by it are always such as may voluntarily be imitated or may occur in a healthy person under strong emotion. In movements that are certainly hysterical we never see single muscles not separately under the control of the will act alone; still less do we see a part of a muscle act alone as in myoclonus. The converse, however, is not true; pathologic movements involving the whole of a group of muscles which normally act together under control of the will are not necessarily hysterical, for other functional and even organic diseases may so act on the cortex as to cause motions of the same character.

The more regularly a movement recurs in time, the greater the probability that it is hysterical. Prominence of ideas or emotions as exciting causes makes it probable, but not certain that the disease is hysteria.

Although the movements themselves seem to be characteristic of some other disease, chorea, for instance, any marked deviation from the mode of onset and course of evolution usual in that disease should suggest hysteria as a possible cause. The presence of other symptoms characteristic of hysteria adds greatly to the probability that the movements in question are hysterical, but it must never be forgotten that hysteria may be added to any other disease.

The most characteristic hysterical movement is a rhythmical oscillation affecting one part. For example, the elbow or any other joint may at regular intervals of time be alternately flexed and extended, the hand opened and closed, the head nodded to and fro or from side to side, the tongue thrust out and retracted, and so on. These motions may be slow and apparently deliberate or they may be rapid; their range may be great or small and is often irregular; it is simply the regularity in time that distinguishes them. In a typical case of this kind the diagnosis is easy, for, excepting post-hemiplegic mobile spasm and athetosis, no other disease causes such rhythmic motions. Post-hemiplegic mobile spasm is easily recognized, because the history and physical signs together indicate organic disease, and even the rare cases of athetosis not preceded by paralysis are not likely to be confounded with hysteria on account of less regularity of rhythm, the age and general condition of the patient and difference in mode of onset and course.

Hysteria, however, may cause motions in which rhythm is less conspicuous, a quick clonic spasm perhaps being combined with tonic spasm. In the neck this may simulate true, spasmodic torticollis, the bilateral form of which constitutes retrocollic spasm. The non-hysterical form of this spasm is a formidable malady which generally begins in the second half of life, only very rarely before thirty; although it is more common in females and may be aggravated by worry and grief, the history does not indicate a definite emotional cause; the onset is almost always gradual and chronic; the spasm is limited to the neck; the disease is not markedly affected by mental treatment and other signs of hysteria are generally absent. In the hysterical imitation of torticollis or retrocollic spasm the patient is commonly under thirty; the history, if complete, does indicate emotion or imitation as an exciting cause; the onset is likely to be acute; the spasm tends to spread to the muscles of the shoulder and trunk; it is markedly affected by mental changes and may occur only in paroxysms; other signs of hysteria are almost always manifest.

---

[5] Les Tics et Leur Traitement, Paris, 1902.

[*] Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Next to the rhythmic movements those most characteristic of hysteria are certain highly co-ordinated ones, such as jumping, dancing, gestures of greeting, running about on all fours, acrobatic performances and the like. These may also be rhythmical, and as a large psychic factor is obviously essential to their production the diagnosis of hysteria is at once suggested. In some cases mania may have to be considered, especially if the acts are accompanied by shouting, singing or declamation, and such actions following an epileptic attack, although perhaps hysterical in themselves, must not be mistaken for hysteria alone. The cases of saltatoric spasm described by Bamberger and others, in which the patient makes jumping motions whenever placed on his feet, are regarded by Loewenfeld as mostly hysterical, although increase in reflex excitability has been advanced as an explanation. Any organic disease causing so great an exaggeration of the reflexes would certainly give other signs of its presence. In some of these cases of co-ordinated movements consciousness is impaired and the movement seems to be part of an hysterical convulsion. In others consciousness is fully preserved.

Chorea may be so closely imitated by hysteria as to make the diagnosis difficult; indeed, it is quite probable that the descriptions of chorea have in part been drawn from hysterical cases. Both diseases are cortical, so the motions are such as may occur voluntarily or under emotional stress, and in both the symptoms are aggravated by emotion or attention. In true chorea the motions succeed each other with no regularity as to time, as to the part of the body affected, or as to range of motion.

In hysteria the motions are more regular as to time, being the rhythmic motions already described, but affecting a larger part of the body. They are also more nearly regular in the order in which they succeed each other and in their range. Hysterical motions are also likely to have more of a staccato character as though produced by isolated faradic shocks. Beyond this I know of no rule that does not require qualification. Hysterical movements are more likely to be grouped in distinct paroxysms with intervals of complete or relative freedom from spasm, but they may be continuous and true chorea may almost disappear during rest and quiet, even in the waking hours. A gradual onset, in a child or pregnant woman, without emotion or imitation as a probable cause, with involvement of the face and tongue, with voluntary motions and speech characteristically embarrassed in the early stages and prevented in the later ones, with rheumatism or endocarditis as a complication, would, of course, be proof of the genuineness of the chorea. But an abrupt onset after an emotional disturbance is by no means proof of hysteria, since, according to Gowers, from 20 to 25 per cent. of the cases of true chorea have fright as the exciting cause, and while the onset is generally gradual, beginning some days after the fright, it may be abrupt without any interval at all, the tremor of fright passing directly into the choreic motions. Loewenfeld thinks that these cases will ultimately be separated from those of infectious origin, and this seems probable, but the line has not yet been drawn. Even the presence of unequivocal signs of hysteria, although of great importance, could not be conclusive, since hysteria confers no immunity to chorea.

Hysterical movements of a limb may occasionally simulate Jacksonian epilepsy. As both diseases are cortical the character of the movements and the order in which they spread may be the same in each, and, in the absence of unequivocal signs of organic disease on the one hand and of signs of hysteria on the other, the diagnosis may be difficult. Under the influence of Charcot, Ballet and Crespin made a careful study of the means of differentiation. According to their researches, in true Jacksonian epilepsy, if many attacks come close together, there is a notable rise of temperature, the part convulsed remains more or less paralyzed for from a few hours to a few days, and there is rapid mental deterioration. In the hysterical imitation the attacks are especially likely to be numerous and close together, but there is no rise of temperature, no paralysis and no mental deterioration. Moreover, according to Gilles de la Tourette and Cathelineau, after an hysterical attack in any form, the urine for 24 hours shows a diminution in the total solids, a diminution in the total phosphates and an increase in the proportion of earthy phosphates to alkaline phosphates, whereas after an epileptic attack the total solids are increased and the relation of earthy to alkaline phosphates is unchanged.

Two of my patients have suffered from spasmodic closure of both eyes, occurring especially when fatigued, worried or in any way agitated and often at the most inopportune time, sometimes involving danger. Both cases seemed to be hysterical, as no sign of organic disease could be found, and as the neurasthenia, which was present, could not alone account for a spasm. But as between hysteria and some other form of functional spasm I could not be certain, as unequivocal signs of hysteria were lacking.

In prognosis and treatment we must be guided mainly by the principles applicable to hysteria in general. The disease being functional and having its origin in idea and emotion, a cure is always possible, provided false ideas may be corrected and emotional serenity obtained. On the other hand, hysterical movements are generally obstinate in their persistence; hysterical chorea, for example, has a longer average duration than genuine chorea.

The patient must be encouraged to expect a cure. A straightforward physician may be at a disadvantage in not being ready to promise as much as a charlatan, but he should choose to err, if at all, on the side of cheerfulness and overconfidence, for this is a case where "he who doubteth is damned." The patient should be taught to be vigorous in carrying out his voluntary actions, but to relax the muscles when at rest, and not to attempt to hold back the objectionable motions by force, but rather to let them go on as they may while trying to divert attention to something else. When any action is harmful it ought not to be thought of at all; even resolving not to do it makes the idea of it vivid and tends to start the prearranged mechanism into action. Systematic gymnastic exercises may be made very useful, but they must not be excessive, and their oversight can not safely be entrusted to a "professor" of physical culture. Any local disease or defect causing irritation should be properly treated without magnifying its importance. Impairment in general health may require attention, and the systematic rest cure may be the best means of improving nutrition, but mental influences will always be paramount in importance. If the patient's mental processes can not be happily directed all the rest will be of no avail: if they are so directed the rest will be easy.

DISCUSSION

ON PAPERS OF DRS. SPILLER, PATRICK AND PERSHING.

Dr. Charles K. Mills, Philadelphia, declared that he believed Sydenham's chorea to be due to the action of some infection or toxin on a nervous system exhausted by such causes as the severe cold of a protracted winter, overwork, or a nervous strain of some kind. He said that he believes Huntingdon's chorea to be one of the so-called developmental or family affections. It usually comes on at a certain decade, at about the age of puberty or of adolescence or even before puberty. It begins insidiously, with an imperative or semi-imperative movement, which increases gradually until the whole body is involved, and eventually mental deterioration takes place. Dr. Mills thinks that in many cases of chorea there is a disseminated neuritis in certain stages, just as there may be arthritis or endocarditis. He considers that rest is one of the best methods of treatment of Sydenham's chorea, and that even in the minor cases every attention should be given to hygienic treatment. The most useful drugs are the old-time remedies like arsenic. Dr. Mills has had some success with the use of conium combined with arsenic and with both drugs combined with the rest treatment. He believes that some form of carefully regulated exercise should be used as complement to this treatment. He did not agree with Dr. Patrick that torticollis comes within the domain of the tics.

Dr. B. Onuf, Sonyea, N. Y., mentioned briefly a patient who at intervals for about fifteen years had had blepharospasm and spasm of the internal recti muscles, of the pupil, and of the accommodations. She was unable to read at any distance greater than two or three inches. On ophthalmoscopic examination, the fundus would at one moment be clear and at another become dim, or would disappear almost entirely; after atropinization of the eyes the picture of the fundus became stationary and the patient showed then a fair vision for a distance. Dr. Onuf discovered that about fifteen years ago, when the disease apparently first began, she went to an oculist who prescribed some "white" glasses and that after a time the spasm disappeared. She said that she had worn dark glasses previous to that time. Dr. Onuf concluded that this spasm was due to an error of refraction, giving rise to strong efforts of accommodation in order to see better. The accommodation, on the other hand, caused convergence of the ocular axes and also contraction of the pupil. The thing that puzzled him was how the blepharospasm started. He did not know whether it was a phenomenon of its own or whether it was also due to the refractive error. On studying the case more closely he found that the blepharospasm was not always present, but that it occurred chiefly when the influx of light into the eye was increased very rapidly. For instance, when she took off her dark glasses the spasm would at once set in, while it had been entirely absent while she had them on. He therefore explained the blepharospasm on the ground that the very frequent state of contraction of the pupil, due reflexly to the accommodative spasm or spasm of fixation, made the retina hypersensitive, so that as soon as slight dilatation of the pupil took place the light was much too strong to be born and caused the lids to be closed. The assumption that this was a hysterical condition was confirmed by the fact that she had very marked anesthesia over the entire body with the exception of a small area around the abdomen and another on the inner surface of the knees. The spasm disappeared almost suddenly through some psychic agency, to reappear again, however, after a time, and the fact of its persistency through fifteen years, at longer or shorter intervals, makes it a very interesting case. That refractive errors were really present was shown by the result of examination by Dr. Arthur G. Bennett of Buffalo, who found in both eyes a myopia combined with myopic astigmatism.

Dr. F. E. Coulter, Omaha, Neb., referred to the observations made by Dr. Russell in cases of chorea occurring in pregnancy, in which he reported that the cases most likely to suffer from choreiform movements are those which are pregnant illegitimately, and makes this one of his leading points. Dr. Coulter stated that he has treated several cases of tic with good results. One patient was an old gentleman of 64, the condition being of four or five years' duration. Dr. Coulter used the static spark and suggestive therapeutic measures. Beyond small doses of fluid extract of gelsemium, the patient received no other treatment.

Dr. Robert McGregor, Saginaw, Mich., stated that many of the cases that he has had have occurred from fright. One girl, aged about 10 years, had an attack dating from a night when she saw for the first time the flashing of a searchlight. Another case occurred from an experience with a runaway horse. It is difficult to deduce any conclusive idea as to why chorea should result from fright. Of course, it may be assumed that when such a case occurs there is to begin with an unstable condition of the nerve centers and that the equilibrium is easily disturbed. He has had patients also who became melancholic as a result of fright. In those cases of melancholia resulting from fright the trouble is very often ascribed to malnutrition of the nerve centers in the brain as a consequence of shock, and this explanation may be used to show why chorea results from fright. Dr. McGregor's experience with chorea has led him to believe that in the majority of cases it is due to some toxic or autotoxic influence. He has had cases where the chorea appeared to be due to some article of diet. For instance, in one case, in a girl 12 years of age, who was particularly fond of veal, he treated her for about three months before he discovered the effect veal had on her system. As soon as the veal was stopped she became well and free from the chorea and remained so for about eighteen months, when she again indulged in her liking for veal and again became choreic. This might be regarded as an idiosyncrasy, but idiosyncrasies are factors in these cases.

Dr. Arthur S. Hamilton, Independence, Iowa, stated that the cases of chronic chorea to which Dr. Spiller referred were observed in a service at the State Hospital for the Insane at Independence, Iowa. Dr. Hamilton has been struck with the rather large number of cases seen at the hospital and he has been inclined to think that the disease is possibly not so rare as it is generally supposed to be. In a practically continuous series of 634 deaths, the six cases with which he was working occurred, with two others which he was unable to report. It seemed to him that the name "chronic progressive chorea," as has been suggested by several, is preferable to "hereditary chorea," particularly since, so far as his observation goes, all cases of chronic chorea in the aged, except certain ones said to be associated with gross organic lesion such as cerebral hemorrhage, belong to the same class. If one accepts the term hereditary chorea, it, in a way, requires the production of a history of hereditary predisposition and this, he knows from experience, is not always easy to elicit, even when it exists, and besides, like all other hereditary diseases, this one must have a beginning somewhere and even if the most careful search of the ancestry fails to reveal anything, it can not be said that the disease will not appear in the offspring of the patient when they are sufficiently advanced in years. Nevertheless, hereditary predisposition is often a striking feature and it has been present in all of his cases except two In one of these the disease has occurred in the children, and of the other patient he has no family history. In a patient still living, whom he has had opportunity to study, the history is rather remarkable. The chorea began with the maternal grandmother, who, with two sisters, was affected All the female descendants of these women except two have had the disease and in each instance it is said to have come on after a pregnancy. The two women who constitute the exceptions have never been married. The maternal grand mother had two brothers and these, with all the male descendants of the three women, have always been free from the disorder. That the chorea has always been confined to the female members of the family, Dr. Hamilton thinks, is sufficiently established, but he is inclined to doubt that in each instance it appeared after a pregnancy. It seems to him more likely that, in some of the cases at least, the pregnancy simply caused the symptoms to become worse and in that way enabled the disease to be recognized.

Of the six cases before referred to, three died with a more or less well-marked pneumonia, probably due to aspiration, as swallowing was difficult in all cases. One died of streptococcus infection. In two instances the patients became unconscious and died without apparent cause other than the progress of the disorder. In one patient, 63 years old, autopsy showed extreme atrophy of the convolutions of the brain; in another, who died at 85, the atrophy was certainly not greater than one would expect at that age. In the others, who all died at about middle life, the atrophy was fairly well marked. Reduction in the number of cortical cells was quite pronounced in some instances and intracellular changes have been quite common, though many of these are such as are seen in other conditions and, doubtless, they are frequently the result of the progress of the disorder rather than its cause. These changes are such as chromatolysis, displacement of the nucleus and pigmentation of the cell. Round-cell infiltration of the perivascular lymph spaces was present in at least one case. In one case—the patient of whom he has practically no history except that his chorea had been present for many years, and in whom the movements were much worse on one side than the other—the cells of all parts of the cord were more or less diseased but in the anterior horns the degeneration was much more marked than elsewhere and in one anterior horn almost no cells could be found. Bodies which appear a good deal like the so-called chorea bodies were quite common in this cord.

DR. S. M. CROWELL, Charlotte, N. C., emphasized the importance of suggestive therapeutics in the treatment of this condition. He said that he thinks that a working knowledge of psychology should be required of all graduates in medicine.

DR. D. J. MCCARTHY, Philadelphia, stated that he made a careful examination of one case of Sydenham's chorea, in which the microscopic examination of the brain showed very marked chromatolysis. There were no hemorrhages, but very marked congestion of the gray matter of the spinal cord and cerebral cortex. He examined three cases of Huntingdon's chorea and found in all three cases a granular degeneration of the cells of the cortex, a very marked atrophy of the cerebral cortex and changes in the cerebral tissues, practically the same thing as those found in general paralysis. In that case the patient showed delusions of grandeur, tremor, and the speech very closely resembled that of paresis. He has also had other cases of Huntingdon's chorea presenting the same symptoms. In one case he used the suggestive treatment for two or three months and the patient was able to gain sufficient self-control to be able to go back to his work, which was that of a carpenter, and worked at his trade for several months, after which he became very much worse.

An interesting case in which the cerebellum was probably involved was that of a child, the eldest in a family, and which was reputed to have weighed 20 pounds at birth. The labor was prolonged, and at the age of 16 months the child developed epilepsy. The patient was admitted to the Philadelphia Hospital with marked chorea and delusions and the diagnosis of chorea *insaniens* was made. Choreiform movements were present. Examination showed marked depression on the occiput and very marked nystagmus. The condition persisted and, if an epileptic attack would develop, the choreic symptoms would become very severe, last one or two days and then clear up. In the interval between the attacks choreiform movements would occur. A very interesting case of tic was that of a little girl who developed the habit of moving her ear voluntarily; she developed a habit spasm affecting these muscles and the ears would move up and down every two or three minutes, because of the habit chorea.

In connection with Gilles de la Tourette's disease, there is a condition due to the excessive use of tea and coffee which gives rise to distinct difficulty in reading and interferes with the use of the eyes. This condition is a condition of intoxication from the use of tea and coffee and is not a condition of chorea at all; it usually clears up with removal of the intoxication and also from rest of the eyes. It is manifested at first by an occasional fibrillary tremor, which increases until practically all of the individual fibers are in active motion—an irregular orbicular-electrical chorea. There is practically no movement of the lids, merely the constant movement of the individual muscle fibers. The patient usually complains of a feeling of tension about the eyes and the contractions become very annoying. This local phenomenon about the eyes corresponds to the electrical choreas, myoclonias, etc., and, like them, is a muscular manifestation of an underlying intoxication.

DR. JOHN PUNTON, Kansas City, Mo., emphasized the importance of suggestive therapeutics in the treatment of tic. He cited the case of a Denver saloon keeper, who was on his way to Philadelphia to be operated on for the sixth time for tic. He was intercepted by some friends and advised to consult Dr. Punton. His history was of tic of the most marked character, and the scars on his face indicated that he had been operated on. He was under the influence of morphin and was taking six grains a day; he also had a saturated solution of cocain with which he bathed his gums every few moments. The case appeared to be a very difficult one, as the paroxysms seemed to be almost continuous, and the standing of the various surgeons who had operated on the patient led Dr. Punton to decide that there was not much that he could do. The patient also said that before leaving Denver he had consulted Dr. Pershing, who advised operation. A surgeon was consulted in reference to extirpation of the gasserian ganglion, but the patient would not consent to that operation. After keeping him under observation for a week, Dr. Punton lost sight of him for about three months. The patient was then purchasing a ticket for Denver, and claimed to be cured. He said that he had been cured by a quack in Kansas City, simply by "magnetic healing." Dr. Punton said that this case showed the marked influence of suggestive therapeutics in tic. The case surprised him, and now before he advises surgery he always tries to see if he can influence such conditions by suggestive therapeutics.

DR. JOHN H. W. RHEIN, Philadelphia, reported the pathologic findings of a case of Sydenham's chorea which came under his care recently. The patient, a boy of 12, died during the second week of the second attack of the disease, the result of a sharp attack of pneumonia of two days' duration. By an examination of the specimens so far Dr. Rhein has been able to demonstrate the presence of capillary hemorrhages in the cortex, and in the muscle a few fibers were found in which there was loss of striatum and slight vacuolation of the muscle substance. Dr. Rhein stated that he has had the opportunity of studying a great many cases at the Orthopedic Hospital and Infirmary for Nervous Diseases in Philadelphia, and he believes it can be concluded that all reflexes are increased in a great many cases and diminished in a certain number, and that if there is anything characteristic at all in reflexes it is that they are capricious. He has seen a great many cases treated by arsenic and has had an opportunity to study the histories of a great many more (probably over 1,000 in all), and is forced to conclude that the development of neuritis during treatment by arsenic is very rare indeed. Choreiform movements may exist in certain rare cases of locomotor ataxia, and two years ago he reported a case of this character at the Saratoga session of the American Medical Association.

DR. WHARTON SINKLER, Philadelphia, said that he thinks that one of the reasons why there is so much diversity of opinion of the nature of chorea is that there is a tendency to include under one head many varieties of the disease, some of which have little in common except that one of the symptoms consists in movements of an irregular and spasmodic form. It must be remembered, too, that there are many diverse causes of chorea. Some cases of Sydenham's chorea may be of infectious origin, but they are not by any means all of infectious origin. One could not for a moment believe that cases of chorea induced by fright, as many are, could be due to infection, nor can the numerous cases due to an overstrain of study or school be of infectious origin. There are also met with several types of Sydenham's chorea in which the symptoms vary to a marked extent, so it seems important that in the study of chorea and of choreiform affections one should discriminate more fully between the different forms of the disease which are met with.

Dr. J. A. Hodges, Richmond, Va., emphasized the causal relation of rheumatism and chorea. Having been impressed as a student with the theory that this disease is almost inseparably connected with rheumatism as a causal factor, Dr. Hodges expected to find it in a great majority of his cases; however, during an experience of ten years he has not seen a single case of chorea associated with rheumatism. Likewise, he has only seen two cases suffering with heart lesions and only two that were supposedly due to toxins, though he is not absolutely positive about these, as neither case died and he did not have the opportunity of extending his investigations into the definite cause of the disease. Many neurasthenic conditions, he believes, may be the cause of this disease. Dr. Hodges referred to the calmative effect of iron on muscular tissues. In a number of cases in which neither small nor large doses of arsenic would control the spasmodic manifestations, iron caused marked improvement.

Dr. Albert E. Sterne, Indianapolis, stated that a great many cases of tic of the convulsive sort have absolutely failed to be benefited by any method that he has ever employed. The older the patient is the poorer the prognosis becomes. The prognosis is very much better in children and decreases as the patients advance in age. There must be a fundamental weakness for the manifestations exhibited in chorea, because the same elements which produce chorea in these individuals have absolutely no effect on persons not predisposed to the condition through fundamental nervous weakness. He believes that there is a very distinct relationship, in a large percentage of cases, between Sydenham's chorea and acute arthritis. It is perfectly natural in a predisposed case that there be a joint manifestation which is frequently overlooked. He has seen many cases beginning in chorea which have developed heart disease only, or arthritis and endocarditis, successively. Chorea may be either the first or the last in the trinity of diseases. In the case of a child which had injured itself by cutting with a piece of tin, the wound would not heal, but remained open, and the child successively developed arthritis, endocarditis and chorea; all disappeared under treatment, but again she developed arthritis, endocarditis and chorea, and died. Dr. Sterne could not recall a single case where tuberculosis was associated with chorea.

Dr. W. C. Jones, Walnut Springs, Texas, declared that in his state there is a great deal of chorea and very little rheumatism, and still less cardiac trouble.

Dr. Wm. G. Spiller, Philadelphia, briefly referred to a case which at first was under the charge of Dr. Mills and which then passed under his care. The patient was operated on, the spinal accessory nerve being resected and two inches removed. The man continued to jerk his head, and a Keen operation was performed and the nerve supply of the muscles of the back of the neck and finally the nerve supply of the corresponding muscles on the other side of the neck cut also. The patient left the hospital very much improved. Dr. Spiller recently saw a patient who had convulsive movements of the muscles of the neck and of the face, who was discharged from the hospital [illegible]red after resection on each side of the spinal [illegible]sory nerve, but he stated that he failed to see how [illegible]ld have [illegible]ed the movements unless by suggestion [illegible] mal[illegible] re[illegible] senile chorea as a more serious con[illegible] in cases of [illegible] chorea and thinks it may be di[illegible] [illegible] reported that [illegible] the senile forms from Huntingdon's chorea. He thinks that at times there is a relation between Sydenham's chorea and rheumatism but that it is often much exaggerated.

Dr. Hugh T. Patrick, Chicago, confirmed Dr. Spiller's statement that implication of the muscles of the eye is very unusual in chorea. Aside from occasional choreiform rolling of the eyeballs, he had never seen marked implication of the eye muscles until recently. A few months ago he saw a boy of 5 with very severe chorea, confining him to bed, and the eyeballs were in constant, irregular, jerky motion. He had never seen anything approaching it except in a few cases of very grave organic disease, and when he first looked at the boy he supposed he had to deal with some serious lesion. The case, however, proved to be a typical one of Sydenham's chorea, and the child gradually recovered. In the treatment, he favors very large doses of arsenic. His opinion is that large doses will produce effect when smaller ones will not. He has had only one case of arsenical multiple neuritis caused by administration of the drug in large doses. That he thinks was not all his fault. He was giving arsenic at that time hypodermically in large doses, which he has since stopped. He went away on a vacation and the case, he thinks, was not watched as carefully as it should have been He always watches the knee-jerks with extreme care, and if he sees any sign of their disappearance or weakening, he stops the drug at once, as this is a sign of beginning neuritis. It never occurred to him to treat a case of chorea by hypnotism.

Dr. Howell T. Pershing, Denver, stated that he believes in large doses of arsenic for chorea, but that he has long since ceased to use Fowler's solution. He now gives cacodylate of sodium in a 1 to 60 solution, which corresponds in arsenical strength to Fowler's solution. It can be given in doses up to 20 and even to 30 minims three times daily without causing any gastrointestinal disturbance. He has had no cases of arsenical neuritis since he began using it, five years ago. He stated that he has never recommended an operation in any case of that kind, though he has been present at and has consented to such operations.

THE RADICAL OPERATION FOR EMPYEMA OF THE FRONTAL SINUS.*

W. FREUDENTHAL, M.D.

NEW YORK CITY.

The practice of rhinology some years ago was in great danger of becoming monotonous. At our conventions the papers on reflex neuroses, adenoids and deviated septa were too numerous and were discussed over and over. What a pleasant change has taken place since, and how differently we treated "nasal catarrh" in the past from what we do now! Each case of atrophic rhinitis and of ozena is a study in itself, and every disease of the accessory sinuses means good judgment and labor. But just this change has lent new interest to our work. Foremost in this respect are the affections of the frontal sinus.

In the paper which I have the honor of presenting to you, principally the chronic forms of suppurative frontal sinusitis are dealt with. In order not to be misunderstood in my conclusions, it will be wise to state from the start that by far the great majority of cases improve under intranasal treatment. And thus the patients are enabled to live for many years, now and then suffering little or more discomfort. In other patients the symptoms are somewhat more pronounced, but many would rather endure them than to undergo a serious operation.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Before we decide on radical treatment by external operation we should exhaust all means possible to afford relief by intranasal procedures. It is an experience common to all of us that acute cases readily yield to a mild treatment, the exceptions only proving the rule. And I have nothing to add to this, excepting one case that occurred in the practice of a well-known colleague in a neighboring city.

Case 1.—On Feb. 20, 1893, I was called to see Mrs. ——, who had been treated a week for typhoid fever. She had fever ranging between 101 and 102 F., and suffered greatly from a constant deep-seated pain over the right eye; constipation was also present. From the start she insisted on consulting a rhinologist, but the attending colleague objected on the ground that the frontal headache was due solely to the typhoid fever. Finally he was discharged, and his successor called me in. The pain was so pronounced that one could hardly touch the affected parts. The patient was unable to sit up in bed, and under the circumstances the examination was rather difficult.

Examination.—I found the spleen somewhat enlarged, no roseola and no pain over the abdomen. Anterior rhinoscopy revealed a highly congested and enlarged middle turbinal, between which and the septum, after cocainization, pus oozed out.

Treatment.—Removal of the anterior ethmoidal cells, followed by washing out of the frontal sinus, which was the seat of the acute empyema, brought great relief to the patient at once. Subsequent daily irrigations of the sinus and applications of silver nitrate removed all difficulties within five days, the patient being completely restored to health. The shortsightedness of the first attending physician is incomprehensible.

During and after an epidemic of influenza, we have all seen cases that yielded to mild treatment. I am fully convinced, however, that many a case failed to improve and puzzled the attending physician by simulating acute mania or the like. But we are not to discuss these today, and I shall now pass to the chronic forms of frontal sinusitis.

CHRONIC FRONTAL SINUSITIS.

Diagnosis.—The diagnosis of these cases is not always simple, and I wish we had some safe method by which we could always determine at the first examination whether or not an empyema of the frontal sinus exists. Of the different symptoms mentioned in text-books, the tenderness over the sinus on slight or strong tapping or on pressure was absent in some of my most characteristic cases, while in others it was quite marked. Asthenopia was sometimes a prominent feature, and I agree with H. Manning Fish that this sign comes more in evidence when the flow of pus from the sinus is temporarily checked.

Transillumination is mentioned here only on account of the peculiar behavior in one case. This was a gentleman with distinct empyema of the right frontal sinus, who was under my observation for nearly four years. The flow of pus continued day after day for years, the middle turbinal was absent, and one could easily reach with a probe far up into the sinus, which apparently extended a good distance above the eyebrow. Irrigation of the sinus was also very easy. Now, in applying the electric lamp for the purpose of transillumination, a large, bright area could be seen on the affected side, which was in strong contrast to the healthy side, which appeared much darker—just the opposite to what was to be expected. The affected sinus was apparently much distended, and, since the flow of pus was no longer obstructed and the sinus emptied constantly, there was nothing to prevent the rays of light from penetrating the sinus walls and producing the translucency.

The most reliable evidence is afforded by probing and washing out the pus from the sinus. This is by far the safest way of reaching a diagnosis. The probing itself is difficult. Indeed, it is rarely possible to enter a sinus by passing a probe along the frontonasal duct, and I agree fully with Charles H. Knight[1] when he says that "one is quite likely to get into the anterior, or fronto-ethmoidal cells, or even altogether fail to find the orifice of the canal." A perfectly thorough exploration of the sinus cavity can not be made with the probe. We are handicapped in many ways by the narrowness of the field in which we have to work, by copious hemorrhages, etc. Even on the cadaver it is impossible to do this or any operation completely through the nose. The reappearance of pus in the middle meatus after syringing the antrum of Highmore signifies that its origin lies higher.

Another important point arises now, as Hajek correctly says, viz., we have to decide whether the pus comes from the frontal sinus alone, from the anterior ethmoidal cells discharging into the infundibulum, or from both. It is sometimes extremely difficult to decide this, and mistakes in this direction are not infrequently made.

CHOICE OF METHODS OF TREATMENT.

Having reached a definite conclusion regarding the condition of the frontal sinus, what are we to do? Are we to treat our patients by intranasal methods, and how long are we justified in following up that course?

It is but natural that we should attempt to establish free drainage intranasally. If we succeed in that way by simply washing out the sinus, we run no risk in continuing this treatment for some time. But in most cases we have to remove the ethmoidal cells, and herein lies the great difficulty. The ethmoidal labyrinth, as Hajek correctly points out, can be freely opened through the nose, but not totally resected. The cribriform plate is dreaded, as a perforation of it will lead us directly into the cranial cavity.

Although, in a discussion on this topic before the Section on Laryngology of the New York Academy of Medicine, several colleagues reported that they had met with this accident and the patients nevertheless recovered perfectly, still it is at least unpleasant and does not bring the patient nearer to a cure. Still, we can give a good deal of relief to the patient by intranasal methods and are justified in continuing it—of course, with the consent of the patient—until threatening symptoms set in. But do not let us forget that such an empyema is in some instances a constant menace to the patient, and that other infections may arise from it. Permit me to quote the following case, which, though no positive proof of that theory, is nevertheless very suggestive:

Case 2.—Mr. R. N., aged 45 years, had the grippe four years ago. Directly afterward he began to suffer from "nasal catarrh" and headache. Two years later he caught a cold and became hoarse, which condition lasted for several weeks. From that time on he occasionally suffered with sore throat. He came to me on account of hoarseness, which hindered him in business.

Examination.—On my first examination a dyspnea and a constant cough, with long inspiratory stridor, was noticed; little expectoration. In the larynx I found perichondritis of both arytenoids, which was the cause of the dyspnea. Examination of lungs and sputum, negative. In both nostrils there was marked atrophy of all structures; he removed masses of scabs by daily syringing. Probing and washing out of both frontal sinuses was done immediately, and at once he told me he had less difficulty in breathing. From that time on I frequently repeated irrigation of the sinus, and then the patient generally felt the same relief. But this was only a subjective sensation. Objectively, in the discharge from the frontal sinus, tubercle bacilli were detected at a time when the findings of the sputum were negative. Later on the sputum also showed tubercle bacilli, and finally physical signs of tuberculosis developed over the lungs. Although there is no direct proof of a communication between the affections of the frontal sinus and the larynx, it is *only natural to associate both under the same etiology*, as the possibility of a lymphogenetic infection of the latter from the sinus is very great. Therefore, I proposed to perform tracheotomy and immediately afterward do radical operation on both frontal sinuses. This seemed to me the only rational way of rendering a cure possible. The patient, however, lost two valuable months in delaying the operation and afterward disappeared.

---

[1] Knight: Diseases of the Nose and Throat, p. 94.

Formerly a radical operation was considered necessary only when one of three symptoms was present, viz., brain pressure, swelling of the frontal region due to expansion of the frontal sinus, or dislocation of the eye, or all three. Since the genial Berlin surgeon, Dieffenbach, first performed that operation we have changed our views as to its indications. Nowadays, after treating the patient for several months and exhausting all kinds of intranasal treatment, it is our duty to propose an external operation under the following conditions:

1. When the purulent discharge is copious and the patient apparently loses ground.
2. When the discharge is fetid and combined with persistent headaches.
3. When the above-mentioned "classical" symptoms are present.

A combination of any of these symptoms naturally makes the indication so much more imperative.

After coming to a conclusion as to the necessity of an operation another difficulty arises, viz., which method is to be followed? Let me emphasize at once that there is no operation that will answer all purposes. Each case has to be treated individually, and each operation requires special rules.

ANOMALIES IN THE SINUSES.

The more I operate in this field, and the more sinuses I open in the cadaver, the more do I see that the variations in the size and shape of the frontal sinus are extreme. It is not very unusual to find the sinus entirely absent, or only rudimentary on one side and very large on the other. In 24 cadavers which I dissected I have found the sinus absent on one side three times. Repeatedly a cell was found between the two sinuses. In one case this cell extended quite a distance up on the left side, although there was no sinus at all. On the other side the sinus extended sharply from the median line all along the supraorbital margin.

A. Logan Turner,[2] our esteemed guest from Edinburgh, in his comparative studies found that the absence of one or both sinuses was not so very uncommon as may be thought; in other words, there was no cavity extending into the vertical portion of the frontal bone "This, however, does not exclude the possibility of the existence of a small frontal air space between the two laminæ of the orbital plate." Whether this air space is identical or similar to the above-mentioned cell which I found I can not decide, but it is probable. The difference in the size of the sinuses is sometimes very pronounced. More important, however, in case of operative intervention, is the difference in their height. In many cases the upper wall of the sinus does not even reach the supraorbital margin. This I consider of such extreme importance for Killian's operation that we always should be on our guard against any such occurrences. Mistakes can often be avoided, but certainly not always. We shall speak about this later on.

METHODS OF OPERATION.

A colleague who has done good work along this line is Arthur Hartmann[3] of Berlin. In his atlas he recommends an operation which is very much like the one we now frequently use.

One of the first to perform this operation radically and on a larger scale was Jansen. His incision along the eyebrow to the supraorbital notch is well known. The bony wall is opened just above the internal angular process of the frontal bone. At this point the bone is thinner than on the anterior surface and can be easily perforated. Then he removes the lower wall of the sinus, and in large cavities the edge of the anterior wall, and closes the external wound. There is no doubt that with this method the ethmoidal cells can easily be reached, but the exploration of the frontal sinus is not so easily accomplished.

In this respect the method of Riedel, who removes the anterior and orbital wall, offers greater advantages. but most authors agree that the cosmetic effect is a bad one. I omit here the description of the well-known methods of Ogston-Luc and Kuhnt, since they have been discussed frequently. Kuhnt's method is surely one of the best, but lesions of the infundibular cells of the labyrinth are not accessible. This is a great drawback, as the fontal sinus affections are almost invariably combined with diseases of the ethmoidal cells. According to Hajek's and my experience, the nasofrontal duct is so intimately connected with some of the ethmoidal cells that, in all probability, we can expect an affection of the latter when the frontal sinus is diseased.

Killian's Operation.—Killian of Freiburg, in order to reach all diseased parts, establish perfect drainage and make the cosmetic effect perfect, modified the former methods in vogue and claims excellent results for his own. As his procedure does not seem well known on this side of the Atlantic, you will permit me to give you a short résumé of it:

Killian's method is as follows: 1. Start incision at the temporal end of the eyebrow, cutting directly through the latter to its median end; extend the incision in a graceful curve around to the side of the nose, and cut through the *middle* of the nasal process of the superior maxilla.

2. Incision of the periosteum about 5 to 6 mm. above the supraorbital margin and parallel to it, followed by a second incision through the periosteum exactly in the center of the frontal process. His idea is to remove the anterior and the lower wall of the sinus with the preservation of a bony bridge, believing that this gives an excellent cosmetic appearance after the operation. In the line of the first periosteal incision he outlines the upper border of the osseous bridge he intends to preserve by light taps with the chisel.

3. Opening of the frontal sinus, either above or below the bridge and probing.

4. With chisel and hammer a furrow is made along the first periosteal incision, and principally with bone forceps the entire anterior wall is removed, followed, of course, by curetting of all diseased mucous membrane.

5. The supraorbital margin is next outlined from the floor of the sinus, and the whole floor resected, thus leaving a part of the bone about 5 to 6 mm. wide.

---

[2] A. Logan Turner: The Accessory Sinuses of the Nose, Edinburgh, 1901.

[3] Atlas der Anatomie der Stirnhöhle, Wiesbaden, 1900

6. Resection of the frontal process of the superior maxilla and the rest of the floor of the sinus.

7. Resection of the anterior and middle ethmoidal cells and the respective parts of the middle turbinal.

8. Formation of a flap from the rest of the nasal mucosa, so that there remains a permanent and large opening into the sinus.

There is no doubt but that this operation is the most radical one, and that it apparently offers the best advantages for a permanent cure. But even this method will have to be modified to suit every variety of cases. if such a thing will ever be possible. For the present, I am not ready to recommend it for all cases; and, indeed, opinions differ widely as to the removal of the various parts.

While Riedel advocates the resection of the entire anterior and lower wall and Killian the same with the retention of a small bridge, Jaques leaves the vertical part of the bony wall intact, but removes the orbital part totally. Burchardt,[4] a former assistant of B. Fränkel's, says: "It is contrary to general experience that cavities do not heal without partial removal of the orbital vault." I confess openly that so far as my experience goes, we can not as yet lay down such general rules.

In one case the whole anterior wall was affected and had to be removed *in toto*. On the other hand, in a case which had been operated on nine months previously by a general surgeon, all the symptoms had returned. On opening the sinus I found the lower wall intact but necrotic, and on removing it there was seen near the outer angle of the orbit a small pocket which was almost entirely partitioned off from the rest of the sinus. I have observed similar formations on the cadaver. It must be admitted that I could not have seen this pocket without following Killian's technic, and it is evident that in this case a cure could never have been effected without removing the lower wall.

Siebenmann of Basel praises Killian's operation as an advance in unilateral affections, but claims that his cosmetic results in double sinusitis were not good where the sinuses were very deep anteroposteriorly We shall have to await his further communications before being able to judge of his proposed modifications.

Before opening the frontal cavity we are very often misled as to its dimensions. Even when we succeed in probing the sinus, we are mostly not able to judge of its height. We may believe that the sinus reaches upward above the eyebrow, and in trying to operate after Killian and open the sinus in this manner. we may get into the cranial cavity. Such a case has occurred in my own practice, and according to private information in that of others as well. It may be briefly mentioned here as an illustration and a warning to others:

Case 3.—Miss ——, aged 45, born in England, consulted me on account of a constant purulent discharge from the nose and severe headaches.

Examination.—Both middle turbinated bodies had been removed, and it was easy to probe both frontal sinuses, as well as to wash them out. The flow of pus was very great. I recommended a double radical operation. As this had been proposed already by another colleague, she consented readily, being happy to be freed of her troubles.

Operation.—In the presence of several colleagues, I tried to follow Killian's method exactly. After marking the bony bridge, part of the bone above it was chiseled away, when to our surprise the dura mater presented itself. The patient made a rapid recovery and left the hospital, the wound being entirely closed. I have not seen her since.

Now, what had happened here? We either had probed an ethmoidal cell, or there was some communication with the sinus of the other side, which was the sole cavity discharging the pus. Or we were misled in judging the distance which the probe had entered. I am inclined to believe the first mentioned.

The variations in the size of the sinus are so great that we should enter it only at the safest point, and that is not above the eyebrow. The most extreme variations I have found in my autopsies on 24 cadavers I shall report here. The first one was in a male cadaver, apparently of Indian type. Here the left sinus that did not reach beyond the middle line was very much larger than the other. Its greatest height near the septum amounted to one inch. while on the other side it did not reach the supraorbital margin and was hardly half an inch in height. The second specimen (Fig. 1) is a characteristic type of another variety. The right sinus in this specimen is quite small, similar to the former case, while above it is a large cavity that belongs to the left sinus. You will observe I commenced Killian's operation on that sinus; the bridge has been prepared and a probe is inserted from the smaller lower section of the sinus into the large upper one, which extends further toward the external canthus of the right eye than of the left.

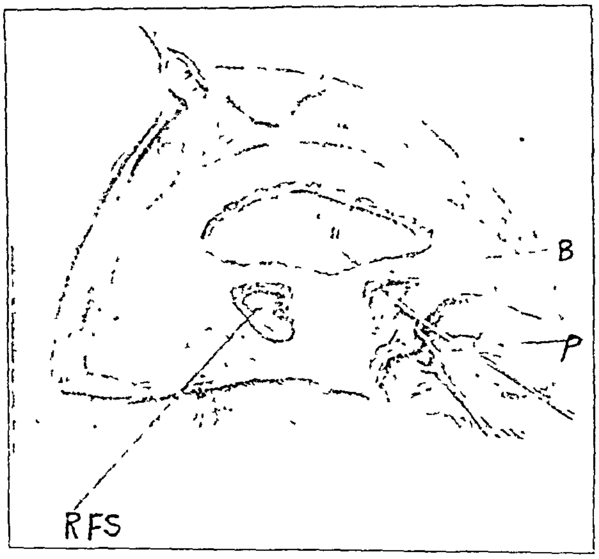

Fig. 1.—B, bridge between the two parts of left frontal sinus; P, probe in left sinus; RFS, right frontal sinus.

Now, if we should have made an opening on the right side above the bridge, we would, in the first case, have entered the cranial cavity, and in the second we would have opened the sinus of the other side, neither of which was desired. At any rate, the above experience has taught me a lesson, viz., never to open the sinus first above the eyebrow. I always start the opening now near the upper inner canthus. Then I can probe the sinus readily and measure its dimensions. This is the only safe way to proceed. My experience on the cadaver has taught me the same, and I would advocate it here emphatically.

After opening the sinus as mentioned, I can easily probe my way and then prepare the bridge from above, if that be feasible. If the sinus ends upward at the eyebrow, we must naturally be satisfied to remove only the lower wall and then there can be no bridge. But when the sinus is large enough I believe in preserving a bony bridge, thus improving greatly the cosmetic effect. It must be mentioned, however, that in some exceptional cases the bone is so affected that it is not advisable to leave any behind. In spite of this, the cosmetic effect is sometimes good, as in one case of mine in which the entire anterior wall had been removed and in which no perceptible depression was left. In another case of mine the bridge broke off during chiseling, but here, too, the result was so good that you can hardly say which side was the affected one. Still, we should not rely on such fortunate occurrences, and be on the safe side by leaving a bridge. The main thing in all these cases is to preserve the periosteum and let Nature do the rest.

---

[4] Arch. für Laryngologie, vol. xv, p. 496.

If during the operation the horizontal incision alone does not give enough space, I do not hesitate for a moment to make another vertical incision after Kuhnt. This is, in men especially, of no importance, and makes the operation easier.

Regarding the removal of the frontal process of the maxillary bone, it is usually easier on the living than on the cadaver, where the bone is healthy and much more resistant. I would sound a note of warning to be careful lest a fracture of the maxillary bone might occur in the living, as happened, on the cadaver, to one of my assistants.

Regarding the formation of a flap for the purpose of keeping the passage open from the frontal sinus to the nose, I must say that this is a very good plan, but I have seen a case where there was no mucous membrane that could be used for that purpose. It was so atrophied that it could not be utilized.

Whatever operation we perform, we should not forget that we are treading on dangerous ground, and that with or without our fault an accident may occur. The case of so experienced a man as Castex of Paris, who lost a patient from meningitis whom he had operated on for empyema of both frontal and maxillary sinuses four weeks after entire recovery from the operation, should be a warning to us.[5]

Having finished the operation, I now close the external wound after putting in a drainage tube that can be removed at will. The primary healing of the wound is preferable, as healing by granulations often, or perhaps always, causes a depressed cicatrix, which is more or less conspicuous. The more we leave the external wound alone, the better will be the appearance afterward. And again, the more we plug the cavity from the outside and the longer we try to keep it open, the more marked will be the disfigurement.

Since the reactive secretion is practically *nil*, no tamponade of the cavity is necessary, and the wound generally heals *per primam*. Sometimes a slight retention of serous fluid causes a rise in temperature. This happened in the case of a young Greek. On the fourth day after the operation he felt pain on touching the wound near the inner canthus. His temperature had varied between 98.6 and 100, when on the fourth day it rose to 104.6. The inner canthus was a little more swollen than on the previous day. On opening it simply with a probe, washing it out with a saline solution and keeping the wound open for a few days, the patient quickly recovered. This place, i. e., the region of the inner canthus, seems to be a favored one for the retention of secretions, as abscesses will develop here also. These abscesses are sometimes of no importance, but usually a spontaneous reopening of the wound will follow with the formation of a fistula. Such a fistula will seldom close, no matter what we try. It means, as a rule, a new operation, and indicates that the first one was faulty in some way. I imagine we all have had such cases, and the wider our experience grows the less frequently will they be encountered. I am convinced that Killian's method is a step further in the direction toward an ideal operation, but it is surely not ideal yet.

And now, permit me to report the histories of some of the most significant of my cases, and I beg your indulgence for narrating first a case on which external operation had not been performed. It may be illustrative of a series of similar cases.

Case 1.—Mr. J. K., aged 60, native of Austria, came to me on account of throat trouble on Nov. 2, 1899. On questioning him, he told me that for the last three years he had had a tickling in his throat, which had grown worse during the last month. He expectorated profusely and his appetite was failing. He had been operated on for nasal polypi about two years before.

Examination.—I found a postnasal catarrh and numerous polypi in both nostrils. The treatment was carried out accordingly, but the patient steadily grew worse. He had lost 25 pounds in weight, had no appetite at all, and slept very poorly.

Treatment.—As pus continued to flow in large quantities, the middle turbinal was removed, and then granulations from the anterior and middle ethmoidal cells curetted. I did this in the beginning quite often and also curetted the lateral cells with a curved ring-knife. The tissues were so friable and the adjacent orbital wall so thin that I always dreaded perforation of the latter. Afterward I was also able to scrape out granulations from the frontal sinus. Only after that was accomplished symptoms commenced to improve. The tissues broke down like paper, but there was no sign of any luetic infection. Although the patient was, and still is, suffering occasionally from dizziness, bad taste in the mouth and consequently loss of appetite, he has refused any radical operation up to the present time. When these symptoms show up I curette the nose and free him of all the accessible pus; then he goes to the country and feels better for some time, until the symptoms reappear. I have had him under observation for five years, and he feels grateful for the relief obtained thus far.

Case 2.—Mr. E. A., aged 39, a musician, called on me first Feb. 4, 1898. He complained of a cold in his head which had lasted for several years. Fifteen years ago, while in South Africa, he had contracted lues, had afterward married, and his wife had given birth to a healthy child.

Examination.—His nose was clogged with a mass of foul-smelling scabs and crusts, after the removal of which a large perforation of the septum with ulcerations on its border could be seen. The left lower turbinal was atrophied, and on the anterior portion of the middle turbinal bare bone could be felt.

Treatment.—This was scraped away, and gradually the whole turbinated body removed. The antrum was washed out repeatedly, and always quite a mass of pus and débris brought away. But pus continued to flow from further up. After curetting away a mass of broken-down tissue I could finally pass a probe into the frontal sinus (June 14, 1898). There was no doubt that an empyema was also present here. It need hardly be mentioned that antisyphilitic treatment had been initiated the first time the patient had called.

The man led a rather irregular life, and disappeared for three months. On Sept. 18, 1898, he returned to me and said he had been playing in a country hotel and had used the potassium iodid sol. 100 drops t. i. d., but had given up the inunctions for obvious reasons. An edema had appeared over the left eye, and the patient felt some pain in that region. Otherwise he considered himself perfectly healthy. I must confess I was not very anxious to do a radical operation in this case, as I was doubtful about the outcome, and I tried my best to bring this process to a standstill by intranasal methods and by pushing the antiluetic treatment to its limit. It seemed as if we were to be successful. But our friend then absented himself again, and returned only when the pus had made an opening through the forehead. Without general narcosis, I enlarged this opening and found an exceptionally big cavity. It reached above the eyebrow surely one inch and extended outward as far as the orbit. There were several sequestra, which were removed, and all the affected parts touched with nitrate of silver in substance. Drainage into the nose was then established and the wound dressed without suture. I am glad to say it healed very nicely within about three weeks and that the scars on the forehead are not very conspicuous now.

---

[5] Intern. Centralbl. f. Lar., p. 166, 1904.

CASE 3.—Mr. C. M., aged 40, a wholesale merchant, consulted me, with quite acute symptoms. He told me he had been unable to breath well through his nose for the last three or four years. Whether there was pus present during all that time he did not know. Three months ago nasal polypi had been removed in several sittings by a colleague. After the last séance he had "dreadful" headaches. But later it seemed as if something had broken, and an abscess opened, and he then felt easier. About ten days ago this pain returned. It was so severe that he could not sleep at all. For the last two days he felt, on the contrary, like sleeping all the time, although the pain had not left him. He was somewhat dizzy, so that his wife had to lead him into my office, his mind did not seem to be perfectly clear, and he answered questions put to him rather slowly and hesitatingly. Temperature, 101 F. No appetite.

Examination.—On examination I found the parts over the right frontal sinus swollen, and the right eye somewhat closed. Great tenderness to touch at supraorbital margin. Transillumination showed shadow on the right side. In the nose there were several polypi and a mass of pus. Considering the seriousness of the symptoms, I advised an immediate radical operation, but the patient preferred to wait. This gave me an opportunity to remove the polypi. I was not able, however, to probe or syringe the frontal sinus, as the slightest touch further up above the middle meatus caused a fainting spell. Nevertheless, the diagnosis was beyond doubt. He was growing weaker, felt like vomiting, etc., when, after eight days, his family consented to an operation.

Operation.—Oct. 4, 1902, 7 a. m. Radical operation after Kuhnt. Eyebrows shaved, horizontal and vertical incision. Periosteum drawn upward and downward; sinus opened above the eyebrow. The cavity, which was filled with pus and granulations, was not very large. The entire anterior wall was affected, and consequently removed, and the rest of the cavity thoroughly scraped out. Drainage into the nose; Myle's tube inserted and sinus packed with gauze. Patient made an uneventful recovery and left the hospital on October 17. The wound was kept open for two weeks longer, when it was allowed to close, which it did within a few days.

Result.—Although the entire anterior wall was taken away, there is hardly any visible difference between the two sides, with the exception of a small retraction where the wound had been drained. I have seen more marked retractions in other cases, and find it best now to close up the external wound immediately following the operation.

One of the most interesting cases I have seen is the following:

CASE 4.—Mr. O. W., aged 59, in the wholesale business, has a most peculiar anamnesis. He had been suffering for the last ten to fifteen years from headache on the left side. It used to "creep up and all over," and then was most severe under and behind the left eye.

History.—His digestion has always been poor, and grew worse two years ago after he had an attack of sunstroke. He became very nervous and sometimes felt like jumping out of the window. His family physician, a well-known and able colleague, took him to different nerve specialists of this city, who are recognized authorities. He went through different cures without experiencing the least relief. Finally he was advised to get away from business and take a trip to Europe. He went to Giessen, in Germany, to visit relatives, to whom he told his different ailments. He snuffled constantly at that time, and somebody advised him to consult a rhinologist. Dr. Reinewald of Giessen saw him and found pus in the middle meatus. He resected the anterior portion of the middle turbinated body and the anterior bulla cells, and advised him to see me after his return to New York. For business reasons he had to remain for a while in Germany, and consulted another specialist, Dr. Warnecke, in Hanover. The latter found an empyema of the left antrum, which he opened with Krause's trocar from the lower meatus. He treated him for a week and again advised him to call on me immediately after his return to New York.

He consulted me first on Dec. 11, 1903, and on being questioned told me that he had had pain in the nose for years and also "catarrh."

Examination.—The opening made by Dr. Warnecke had closed and pus in the antrum was again found. The next day the antrum was opened from the alveolar process, whereupon a great deal of pus was washed out. This, however, according to Mr. W., was not so putrid as that discharged after the first incision by Dr. Warnecke. The daily irrigations of the antrum met with some difficulties, the patient being a potator and of a very nervous temperament, which grew steadily worse. In spite of the irrigations, and every time after them, pus was noticed in the middle meatus. The cause of the disease, therefore, had to be looked for higher up. The removal of granulations and some ethmoidal cells could not be accomplished thoroughly, as the patient objected to it without general narcosis, but probing of the frontal sinus could be done after thorough cocainization. In transillumination the left sinus appeared darker than the other.

Operation.—The diagnosis of chronic frontal sinusitis was made and radical operation proposed. This was performed on Jan. 24, 1904. Both eyebrows were shaved and a horizontal incision made, reaching to the external margin of the eye. Then the periosteum was incised and pushed upward and downward. Very near the middle line, right above the eyebrow, the bony wall was opened with chisel and hammer. The whole anterior wall was found to be affected and removed *in toto,* mostly with bone forceps. The mucous membrane could be lifted up in pieces. The whole sinus was curetted and cleansed with hot sterile water. Then every part of it could be examined thoroughly. As the entrance to the nasal cavity was easily enlarged with a ring knife, and apparently every diseased particle removed, I saw no reason for performing here Killian's operation, but inserted a Myles drainage tube and packed the external wound with iodoform gauze.

I have to mention again that the patient was an alcoholic, and consequently the free use of wine and whisky was permitted.

Hospital Record.—During the day he was greatly distressed with gas, but relieved by enema. Further on during his convalescence a rectal tube always made him feel easier. Temperature in the evening, 99 degrees; pulse, 60.

January 26, 8 a. m., pulse, 68; temperature, 99 degrees; 9 p. m., pulse, 66; temperature, 100 degrees. Passed the day comfortably, but felt somewhat dizzy.

January 27, highest temperature, 99.6 degrees.

January 28, wound dressed, after which he was very nervous for several hours, but comfortable later on.

January 29, 8 a. m., pulse, 60; temperature, 98.2 degrees. Complains of "cloudiness of vision." 7 p. m., pulse, 64; temperature, 99.6 degrees. Is slightly delirious; alcohol rub and plenty of whisky. During the following night nurse remarked, "Very vivid imagination."

January 30, wound dressed and looks healthy. No double vision. Patient rests easily.

January 31, complains of a disagreeable smell. Temperature from one to four years afterward. I have done nearly all the operations except the complete Killian, and my most brilliant results have been accomplished through an operation I have not heard mentioned to-day. That is the thorough removal of the anterior ethmoidal cells and part of the floor of the frontal sinus through the nose. I can show cases with the most obstinate history which have recovered and are well to-day. Killian speaks of his operation as a radical one. I do not see how it can be called that, when a large cavity is left which often contains pus. I have had difficulties with the eye in removing the floor far back beyond the optic nerve. We are liable to have abscess form which may destroy the sight. I think the secret of our success in many cases depends not so much on the amount of scraping and packing, as on securing a good, large opening from the nose into the frontal sinus. The anatomy is more favorable for this and where the ethmoidal cells are large and other conditions are favorable, if the parts can be broken down easily and the ethmoidal cells all removed, we will get our most satisfactory and brilliant results, whether we do the operation beneath the brow or above it. We may be able to educate people to consent to an operation, leaving such deformity as we have seen, and this I am trying to do, injecting some of the cases with paraffin.

As to the difficulty of diagnosis spoken of by Dr. Freudenthal, I have had but little difficulty in getting a small tube in. I wrote a paper on this point along in 1890 and have been doing this work almost daily. One can not do this in a healthy sinus, but usually it can be done in a diseased sinus, and that is where it is desirable. When water is injected and returns full of pus, the diagnosis is differentiated and then one can measure how far up the instrument goes. The morning pain, which goes away in the afternoon, is due to the frontal sinus being half full of pus. Gas forms, and when this gas forces the thickened muco-pus out and escapes itself the pain disappears. I have never had a death under treatment, though one man died who refused operation for a long time and afterward consented. After three or four days he suddenly became unconscious and died.

Dr. E. E. Foster, New Bedford, Mass.—Last fall and winter I saw twelve radical operations on the frontal sinus, done by Professor Killian and his assistant, Doscent van Eiken. The results were excellent. There was one death of an old woman who was practically moribund at the time of the operation. Dr. Freudenthal mentioned the fact that Professor Killian does not shave the eyebrow; Professor Killian's reasons for not doing so are that he has had a few cases where the hair did not return, leaving a very objectionable appearance and cases where the hair grew so long that it was also objectionable. He cleans the brow with soap, alcohol and corrosive sublimate. I did not see an infection of the wound from the hair. He is very careful to remove all cut-off hairs from the skin incision before he continues the incision through the periosteum. An important point regarding the cosmetic results is to make several short superficial cuts at right angles to the long incision, thus enabling the operator, at the end of the operation, to accurately appose the much stretched edges of the incision. Diplopia occurred in several cases, but it was of only short duration. Professor Killian uses a long, narrow strip of iodoform gauze for drainage. He doubles the strip, placing the double end in the temporal side of the frontal cavity; the cavity is loosely packed; the two ends are pushed through the opening made in the floor of the frontal sinus. One end is used for packing in the nose, while the other end is brought out through the nasal orifice. A V-shaped chisel is used in making the supraorbital bridge and the boundaries of the opening through the nasal process of the maxillary bone. It has been stated that a large depression remains after the operation. I did not see any objectionable depressions in Killian's cases. In those cases where the depression is noticeable paraffin is used with excellent results. Post nasal tampons are not used, but the meati on the side to be operated on are packed with long rolls of cotton. The tampon in the middle meatus is removed when the flap is made. The flap is the mucous membrane from the nasal surface of the frontal process of the maxillary bone. The external wound is closed with aluminum wire sutures, except when there has been a fistula or the tissues over the bone have been involved in the inflammatory process, then the wound is only partly closed with a drain. The cases referred to by Dr. Richards were the cases first reported by Killian. Since then he has improved his operation in several important points, and, of course, developed greater skill. The Killian radical operation is not an operation to be attempted by the average operator.

Dr. Emil Mayer, New York City—Does Dr. Turner follow the method of Jansen in using the electrotrephine? Jansen is very fond of using this in his frontal sinus and mastoid work, and it seemed to me the stress laid on avoiding raw surfaces of bone was important.

Dr. G. E. Seaman, Milwaukee, Wis.—My colleague, Dr. Hitz, and myself have been doing work on these cases during the last year, and we had several cases which seemed to be favorable for the Killian operation. We first did the operation on the cadaver a number of times, and were very careful to avoid wounding the pulley of the superior oblique muscle, and succeeded in most instances. In one case operated on, where the frontal sinus was very large, the resulting deformity was considerable at first; this has improved. In that case there was disturbance of motility of the eyes which persisted for some time, but at the end of three months it had passed away. In discussing these cases with Dr. Sifton of Milwaukee he told me that he had operated on a frontal sinus case several years ago and had found the hemorrhage very troublesome. He put a temporary ligature on the common carotid. Does Dr. Turner consider this a recognized procedure? Is it ever necessary or justifiable in his experience?

Dr. C. R. Holmes, Cincinnati—I fail to see how obliteration of the cavity can be done in a large per cent. of cases. In the last ten or twelve years I have dissected a great many heads, and I have had a large number of specimens where the frontal sinus extends back over the orbit and some where it extended back almost to the optic foramen. In such cases I do not see how a radical operation can ever be successfully performed if we have any regard at all for appearance. I think the disfigurement is a very important factor, especially in young women. Even some men are not willing to take the chances of a radical operation if thereby they are to be disfigured for life. The oculist finds evil results from this condition on the eye. I have seen quite a number of cases of diplopia result and while after a time this becomes less, it is because there is a readjustment of the muscle. This, however, means a constant strain on the eyes for the rest of life, due to the effort of both eyes to work together. These people often suffer greatly with headache and exhaustion.

Dr. Kaspar Pischel, San Francisco—Allow me to put on record a case of optic neuritis and paralytic divergent strabismus caused by a suppurative frontal sinus. In spite of an early successful operation atrophy of the optic nerve followed. In order to inform ourselves, before the operation, of the size of the frontal sinus I would suggest taking a skiagram. That will assist in the selection of the method of operation. In Killian's operation the "sinu-nasal" canal might be covered with skin grafts to keep it well open. To prevent a depression of the skin above the eyebrow, part of the sinus might be filled with paraffin covered with absorbable Cargile membrane. The bone flap shown on the screen by Dr. Turner seems to give an ideal cosmetic result. The sinus might then be lined by skin grafts as we cover the bone trough in radical mastoid operations.

Dr. F. C. Ard, Plainfield, N. J.—During the past winter I have assisted Dr. Coakley in a number of operations on the frontal sinus, and his method of operating has not been mentioned in this discussion. He removes the anterior wall, without disturbing the floor of the sinus, and curettes the walls of the cavity with great care, under illumination, and then packs with iodoform gauze. He aims to obliterate the naso-frontal duct, and to allow the cavity to fill up by granulation. Sufficient time has not elapsed in these cases to make sure there will be no recurrences, but there is apparent recovery in all that I have examined, as is evidenced by the fact that the wounds have healed, and there is no pus in the nasal cavities. A case that I operated on early in March by this method has just healed, but it was a very large sinus.

Dr. W. Freudenthal—Dr. Turner has brought up the osteoplastic operations, though he has not done any himself. In some cases I find it impossible to do this because of the broken-down tissue which must be removed. I remember one case where I removed the whole anterior wall, and a new wall formed. I have not seen a case of diplopia. I use atropin before the operation. But these cases of diplopia go more to the ophthalmologist than to us. I must admit that Dr. Myles has had a larger experience than I and he is able to do more with these cases than most of us. In many cases I could not reach the frontal sinus, and it is often impossible to measure the distance. Dr. Turner himself mentions having attempted to enter the right sinus and got into the left one instead. Dr. Foster's point was well taken. The disfigurement in my cases was very slight, probably due to the periosteum being preserved. The last word has not yet been spoken on these operations and we shall have to learn a great deal more. Yet if we can save a few of those cases like the one mentioned in my paper, who was contemplating suicide, we have done a great deal.

Dr. A. Logan Turner—Much more was omitted from the paper that might have been said. We are not yet at the bottom of this question; there is still much to learn, but some day we shall be in better position to deal with these cases. I have not been educated to Dr. Myles' view that we can treat these cases through the nose. As regards treatment by drainage through the nose, I know that there are cases in which satisfactory results have been obtained, but if we consider the anatomic configuration of the sinus, I do not see how we are to expect a cure by this method. There were many points of detail which I did not give fully for lack of time. One point about which I wanted information was in regard to the formation of a flap of mucous membrane described by Killian. Others as well as myself have had difficulty in understanding this point. With regard to the osteoplastic operation, I introduced this procedure from Hajek's new edition. There seems to be something in the Killian method of operating which is approaching more nearly to the result desired, giving excellent curative results with the minimum of disfigurement. I have had no experience with the use of the electric trephine. We can obtain good, smooth edges by the careful use of the chisel. I have always found hemorrhage to be well controlled with peroxid of hydrogen. This stops it very rapidly, just as it does in mastoid work. I do not know whether the common carotid has ever been ligated in these cases or not.

Dr. Holmes said he felt difficulty in seeing how the sinus could be obliterated. I have had no difficulty whatever in doing this, either on the living person or on the cadaver. It is astonishing to see how readily the soft tissues of the orbit rise up while you are removing the floor of the sinus and obliterate the orbital portion of the cavity. It is wise to remove all of the bony floor and not to leave any bone at the apex of the orbit. Further, what Dr. Holmes said about the future of these cases is important. I shall take occasion to find out whether my old cases have developed any eye strain. I did not refer to the method spoken of by Dr. Ard, viz., preservation of the osseous floor. Dr. Coakley probably obliterates the orbital part of the sinus by gradually filling it up with granulations.

Prophylaxis in Surgery.—It has always been my idea, wrote Dr L. Sexton of New Orleans, that if surgeons would spend more time in getting the patient in proper condition to stand the operation, in having everything in readiness, in having assistants trained in what they are expected to do, and also if the least possible time were consumed in performing the operation, and if all lectures and explanations were suspended until the operation is finished, much less of the first necessary poison, viz., the anesthetic, would be required, and we would have fewer cases *in extremis* to deal with after operations.

PRESENT STATUS OF ANTITUBERCULOSIS WORK IN THE UNITED STATES.

SUGGESTIONS FOR A MORE EFFECTUAL CO-OPERATION OF AUTHORITIES, PHILANTHROPISTS, PHYSICIANS AND LAYMEN.*

S. A. KNOPF, M.D.
NEW YORK CITY.

The kind interest with which my first report in 1897 and my second report in 1902 on the tuberculosis problem in the United States was received by the members of the Section on Hygiene and Sanitary Science and of the American profession at large encourages me again to give a bird's-eye view of what is being done in our country in the combat of the great white plague. Between my first and second reports five years had intervened; between my second and third only two years have elapsed. My reasons for reporting after this shorter interval are to be found in the unusual activity of sanitary authorities of the medical profession at large, and of the philanthropic societies and individuals engaged in antituberculosis work. Far greater progress has been made during the last two years than in the preceding five or ten.

There are now no less than forty-eight American and five Canadian associations for the prevention of tuberculosis, working under the names of societies, committees or commissions. The following is as complete a list as I have been able to collect myself up to this date[1] and to Miss Lillian Brandt, the very efficient statistician of our tuberculosis committee in the New York Charity Organization Society, I am indebted for such statistical material as was at her disposal.

SOCIETIES AND COMMITTEES FOR THE PREVENTION OF TUBERCULOSIS, AND STATE COMMISSIONS.

CALIFORNIA.

Southern California Antituberculosis League—F. M. Pottenger, M.D., president, 226 Bradbury Bldg., Los Angeles, Cal.

Tuberculosis Committee of the Medical Society of the State of California—Dr. F. M. Pottenger, secretary, 226 Bradbury Bldg., Los Angeles, Cal.

COLORADO.

Evangelican Lutheran Sanitarium Association of Denver, Colo. —Frederick d'Amour, president; Dr. Henry G. Merz, secretary, 632 17th St., Denver.

Jewish Consumptives Relief Society.—Dr. C. D. Spivak, secretary, 1421 Court Place, Denver, Colo.

CONNECTICUT.

New Haven County Antituberculosis Association—Dr. Francis Bacon, president, New Haven, Conn.

DISTRICT OF COLUMBIA.

Committee on the Prevention of Consumption of the Associated Charities—Dr. Wm. C. Woodward, chairman, 811 G St., N. W., Washington, D. C.

GEORGIA.

Georgia Medical Commission to Investigate the Extent of Tuberculosis in Georgia, and Means of Stamping Out the Disease.—Dr. Charles Hicks, chairman, Dublin, Ga.

ILLINOIS.

Committee on the Prevention of Tuberculosis of the Visiting Nurses' Association.—Dr. Alice Hamilton, 79 Dearborn St., Chicago.

Illinois State Association for the Prevention of Tuberculosis.—Dr. Edmund J. James, president; Dr. Arnold C. Klebs, secretary, Chicago.

Committee on Tuberculosis of the Illinois State Medical Society. —Dr. J. W. Pettit, chairman, Ottawa, Ill.

National Antituberculosis Association, Incorporated in Springfield Ill.—Incorporators: Dr. W. B. Metcalf, Rev. F. M. Carson, C. O. Hanford, Alderman Butterworth, W. R. McDonough, all of Chicago.

---

*The discussion on the papers of Drs. Knopf and Price, in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904, will appear in a later issue with the paper of Dr. Price.

[1] Owing to the large number of papers read at Atlantic City it was impossible to have this report appear before. During the six months since the paper was read a number of new societies have been formed and several new institutions established. Through the courtesy of the editor of The Journal, the manuscript was returned to me in order that I might bring the statistical portion as nearly as possible up to date (January, 1905).

INDIANA.

Indiana Committee of Tuberculosis of the State Medical Society.—Dr. J. N. Hurty, secretary, Indianapolis.

The Antituberculosis Society of Indiana.—Dr. Theodore Potter, secretary, Indianapolis, Ind.

MAINE.

The Maine State Sanatorium Association.—Portland, Me.

MARYLAND.

Maryland State Commission.—Dr. Marshall Langton Price, medical officer, 10 South St., Baltimore.

The State Association for the Prevention and Relief of Tuberculosis in Maryland.—Dr. H. B. Jacobs, president; Dr. Joseph S. Ames, secretary.

MASSACHUSETTS.

The Boston Association for the Relief and Control of Tuberculosis.—A. M. Wilson, secretary, 6 Beacon St., Boston.

Tuberculosis Aid and Education Association.—Miss Edna A. Woolson, secretary, 277 Howard St., Cambridge, Mass.

The Springfield Association for the Prevention of Tuberculosis.—Dr. H. C. Emerson, president, Springfield, Mass.

Worcester Association for the Relief and Control of Tuberculosis.—Earle Brown, secretary, Worcester, Mass.

American Invalid Aid Society.—Mrs. E. W. Waite, secretary, 73 Tremont St., Boston.

MINNESOTA.

Society for the Prevention of Tuberculosis.—Dr. H. M. Bracken, Pioneer Press Bldg., St. Paul, Minn.

Minnesota State Commission (in regard to Sanatoria).—Dr. H. L. Taylor, Chairman, 75 Lowry Arcade, St. Paul, Minn.

The Antituberculosis Committee of the Associated Charities of Minneapolis.—Edwin D. Solenberger, secretary, 738 Boston block, Minneapolis, Minn.

MISSOURI.

St. Louis Society for the Prevention of Tuberculosis.—Mr. F. E. Eaton, president; Mr. G. A. Blickhahn, secretary; Dr. Wm. Porter, chairman, St. Louis.

NEW HAMPSHIRE.

New Hampshire State Commission (in regard to a sanatorium).—Dr. Irvin A. Watson, chairman, Concord, N. H.

New Hampshire Society for the Prevention of Consumption.—Dr. O. B. Douglas, chairman, Concord N. H.

Suncook Association for the Prevention of Tuberculosis.—Suncook, N. H.

NEW JERSEY.

New Jersey State Commission (in regard to Sanatorium).—Edwin A. Stevens, treasurer, 1 Newark St., Hoboken, N. J.

Antituberculosis Committee of the Oranges.—Miss Louisa R. Pierson, secretary, Orange, N. J.

NEW YORK.

Binghamton Society for the Prevention and Cure of Tuberculosis.—Charles W. Fetherolf, secretary, 9 Linden Ave., Binghamton, N. Y.

Tuberculosis Committee of the Buffalo Charity Organization Society.—Dr. P. W. Van Peyma, chairman; Frederik Almy, secretary, 165 Swan St., Buffalo, N. Y.

Committee on the Prevention of Tuberculosis of the New York Charity Organization Society.—Paul Kennaday, secretary, 105 E. 22d St., New York City.

Tuberculosis Committee of the United Hebrew Charities.—Dr. Lee K. Frankel, secretary, 365 Second Ave., New York City.

Committee on the Prevention of Consumption of the United Garment Workers of America.—Henry White, chairman, Bible House, New York City.

Tuberculosis Committee of the Rochester Public Health Association.—Dr. M. E. Leary, 32 South Washington St., Rochester, N. Y.

OHIO.

Ohio Society for the Prevention of Tuberculosis.—Dr. C. O. Probst, secretary, State Board of Health, Columbus, Ohio.

Ohio Commission, appointed by the Governor to investigate the desirability of a State Sanatorium.—Dr. C. O. Probst, secretary, Columbus, Ohio.

PENNSYLVANIA.

Pennsylvania Society for the Prevention of Tuberculosis.—Dr. Lewis Brinton, secretary, 1423 Spruce St., Philadelphia.

The White League.—Mr. Edwin W. Perot, secretary, 1515 Arch St., Philadelphia.

Scranton Society for the Prevention and Cure of Consumption.—Dr. J. M. Wainwright, secretary and treasurer, 627 Linden St., Scranton, Pa.

Henry Phipps Institute.—Dr. Lawrence F. Flick, president, 238 Pine St., Philadelphia.

RHODE ISLAND.

Newport Association for the Relief, Control and Prevention of Tuberculosis.—President, Mr. Robert Frame (president Newport Board of Health); secretary, Mr. Clarence C. Moore, Newport, R. I.

VERMONT.

Vermont Society for the Study and Prevention of Tuberculosis.—Dr. H. E. Lewis, secretary, Burlington, Vt.

Vermont State Tuberculosis Commission.—Dr. H. E. Lewis, secretary, Burlington, Vt.

WISCONSIN.

Wisconsin State Commission for the Prevention of Tuberculosis.—Dr. Gustav Schmitt, 1206 Walnut St., Milwaukee, Wis.

NATIONAL.

National Association for the Study and Prevention of Tuberculosis.—Dr. E. L. Trudeau, president; Dr. Wm. Osler, first vice-president; Dr. Hermann M. Biggs, second vice-president; Dr. H. Barton Jacobs, honorary secretary; Prof. Livingston Farrand executive secretary; Dr. George M. Sternberg, surgeon-general, treasurer. The board of directors is composed of 20 men from all over the states who are particularly interested in the study and prevention of tuberculosis. The following is the present composition of the board: California, Dr. Norman Bridge; Colorado, Dr. S. E. Solly; Connecticut, Dr. John C. P. Foster; Washington, D. C., Dr. George M. Sternberg; Illinois, Drs. Arnold C. Klebs and Robert H. Babcock; Indiana, Dr. J. N. Hurty; Maryland, Drs. Wm. H. Welch, William Osler, H. B. Jacobs and John S. Fulton; Minnesota, Dr. Henry B. Bracken; Missouri, Dr. William Porter; Massachusetts, Drs. Edward O. Otis and Vincent Y. Bowditch; New Jersey, Mr. Frederick L. Hoffman; New York, Drs. Hermann M. Biggs, S. A. Knopf, Edward L. Trudeau and Mr. Edward T. Devine; North Carolina, Dr. Charles L. Minor; Ohio, Dr. Charles O. Probst; Pennsylvania, Drs. Lawrence F. Flick, Mazyk P. Ravenel, H. S. Anders and Leonard Pearson; Texas, Dr. N. M. Smith and Dr. George E. Bushnell of the United States Army Hospital, and Surgeon-General Walter Wyman of the United States Marine Hospital; Dr. H. Barton Jacobs, secretary, 11 Mt. Vernon Place, Baltimore.

CANADA.

The Canadian Association for the Prevention of Consumption and Other Forms of Tuberculosis.—Rev. M. Moore, D.D., secretary, 128 Wellington St., Ottawa, Canada.

Ontario Anticonsumption League.—Rev. C. S. Eby, D.D., secretary, Toronto, Canada.

Montreal League for the Prevention of Tuberculosis.—Dr. A. J. Richer, honorary secretary, 11 Bleury St., Montreal, Quebec.

The St. Francis District League for the Prevention of Tuberculosis.—Dr. E. J. Williams, honorary secretary, Sherbrooke, Quebec, Canada.

The New Brunswick Association for the Prevention and Cure of Consumption.—Dr. William Bayard, St. John, N. B.

BRITISH COLUMBIA.

The British Columbia Society for the Prevention of Tuberculosis.—Dr. J. C. Fagan, secretary, Victoria, B. C.

Before proceeding with the statistical information, permit me first to say a word or two on the work and mission of such organizations. They are, as a rule, composed of medical men and of laymen. Many do educational work alone, others incorporate in their work the establishment of sanatoria; still others make this their exclusive purpose; others again make it their main object to take care of the patients at their homes; but nearly all these associations study the social aspect of tuberculosis in its various forms which are inevitably connected with work of that kind.

A little over two years ago, when I thought the time ripe to form an association or committee of that kind in New York, I laid down the following objects and aims for such an association in a call which was issued at the time, and which finally resulted in the formation of the New York Charity Organization Society's Committee for the Prevention of Tuberculosis:

1. The promulgation of the doctrine that tuberculosis is a communicable, preventable and curable disease.

2. The dissemination of knowledge concerning the means and methods to be adopted for the prevention of tuberculosis.

3. The advancement of movements to provide special hospitals, sanatoria and dispensary facilities for consumptive adults and scrofulous and tuberculous children among the poor.

4. The initiation and encouragement of measures which tend to prevent the development of scrofula and of other forms of tuberculous diseases.

To this call were attached the signatures of Prof. Hermann M. Biggs, Prof. Joseph D. Bryant, Dr. John H. Huddleston, Prof. A. Jacobi, Prof. Walter B. James, Prof. Edward G. Janeway, Prof. Alexander Lambert, Prof. Henry B. Loomis, Prof. T. Mitchell Prudden, Prof. Andrew H. Smith, Prof. Stephen Smith, and my own. Owing to the difficulty of finding a layman with the proper qualification for president of the society, the medical men who had signed the appeal, joined with the New York Charity Organization Society, to form a special committee, of which Mr. Charles F. Cox became president, and Mr. Edward T. Devine, secretary *pro tem.* A number of other prominent physicians, philanthropists and trained charity workers joined the committee, and it has now its regular paid secretary and its paid statistician.

Concerning the work it has done during the few years of existence, permit me to quote the following it from the handbook issued by the committee: During the winter of 1902-1903, 91 lectures were delivered under the auspices of the committee in the various settlements, Young Men's Christian Associations, Young Men's Hebrew Associations, churches, public schools, etc. Most of these were in English, but a number of them were delivered in German, Bohemian, Italian, French and Hebrew (Yiddish). During the same period this committee has distributed 77,000 printed lectures and leaflets of instruction. One of the most important circulars of all I consider the one issued in regard to the frequently advertised "absolute consumption cures." I consider this so important that you will permit me to reproduce it here in the hope that other organizations may copy it and thus protect many unfortunate people.

> WHEREAS, It has come to the knowledge of the Committee on Tuberculosis of the Charity Organization Society that many so-called specific medicines and special methods of cure for tuberculosis have been and are being exploited and widely advertised; and
>
> WHEREAS, The advertisements of some of these cures have made such reference to the Tuberculosis Committee of the Charity Organization Society, or to some of its members, as to create the inference that this committee, or its members, recommend or advocate the use of many such so-called specifics or special methods of cure for pulmonary tuberculosis, or consumption; and
>
> WHEREAS, There is no specific medicine for this disease known, and the so-called cures and specifics and special methods of treatment widely advertised in the daily papers are, in the opinion of the committee, without special value, and do not at all justify the extravagant claims made for them, and serve chiefly to enrich the promoters at the expense of the poor and frequently ignorant and credulous consumptives; therefore be it
>
> *Resolved*, That a public announcement be made that it is the unanimous opinion of the members of this committee that there exists no specific medicine for the treatment of pulmonary tuberculosis, and that no cure can be expected from any kind of medicine or method except the regularly accepted treatment, which relies mainly upon pure air and nourishing food.

Add to this the nearly 50,000 circulars distributed by the medical inspectors of the board of health, and an idea may be obtained of the really enormous educational work done in New York. Of the other work done by the tuberculosis committee, we must note its protest to the governor against the signing of the Goodsell-Bedell bill, the protest against dwarfing the present tenement-house laws, the urging of the destruction of the celebrated "lung block," and the constant urging of the establishment of sanatoria for the consumptive poor of New York.

Besides this work, the sub-committee on treatment of our larger committee has during the first year of its existence taken care of 211 families having tuberculous members. The handbook above mentioned will give those who desire to learn more of the New York Tuberculosis Committee and what it has done much additional information. All I hope to have shown in this present meager report is what a tuberculosis committee can do when it has the support of the medical profession, the philanthropist and the municipal authorities.

I must not leave the subject of tuberculosis organizations without referring to one which has just been formed[2] under the name of "The National Association for the Study and Prevention of Tuberculosis." As those who have followed this movement will know, this association is the outcome of the earnest desire on the part of many American physicians interested to have a representative American Association for the study and the prevention of tuberculosis. The movement started with a conference called together at the occasion of the Tuberculosis Exposition in Baltimore and the subsequent appointment of committees and the framing of constitutions and by-laws. The objects of the association are (*a*) the study of tuberculosis in all its forms and relations; (*b*) the spreading of knowledge about the causes, treatment and prevention of tuberculosis; (*c*) the encouragement of the prevention and scientific treatment of tuberculosis.

I know that I express the sentiment of this Section, which has always been so deeply interested in the tuberculosis subject, in wishing this new organization God speed and a useful and glorious career. The calling into life of this national society is, to my mind, one of the most important events in the history of American medicine.

The next most important point concerning the present status of the antituberculosis work in the United States would be a list of sanatoria, special hospitals and homes devoted to the exclusive treatment of patients suffering from tuberculous diseases. I append herewith a list of such institutions existing at the present time in the United States and Canada:

LIST OF SANATORIA, SPECIAL HOSPITALS AND CAMPS FOR THE TREATMENT OF PULMONARY TUBERCULOSIS.

ARIZONA.

Mercy Hospital, at Phoenix, Ariz.; 20 beds.

St. Mary's Hospital and Sanatorium of the Sisters of St. Joseph, at Tucson; 30 beds.

"Palm Lodge" Sanatorium and Tent Colony for Incipient Tuberculosis, at Phoenix, Ariz.; Dr. Henry M. Stone, res. phys.; 55 beds; private.

CALIFORNIA.

Dr. J. W. Barlow's Sanatorium, at Los Angeles; 15 beds.

Esperanza Sanatorium, the Sierra Home of the Open-air Cure for Pulmonary Diseases, at Altadena, Cal.; Dr. F. C. Melton, res. phys.; private; 50 beds.

Ranch of Mr. N. O. Nelson, at Indio, Cal.; private.

Pottenger Sanatorium for Diseases of the Lungs and Throat, at Monrovia, Cal., Dr. F. M. Pottenger, med. dir.; 50 beds; private.

Trinity Settlement, at Redlands, Cal.; private; Dr. Moseley, med. dir.

Ballard Pulmonary Sanatorium at Pasadena, Cal.; Dr. W. H. Ballard, phys.-in-chief; 25 beds; private.

The Mentone Sanatorium, near Redlands, Cal.; A. R. Schultz, manager; Dr. Fred J. Koepke, res. phys.; 50 beds.

Tents for Tuberculous Patients of the Mendocino State Hospital for Insane, at Talmage, Cal.; Dr. E. W. Wing, supt.

COLORADO.

Glockner Sanatorium, at Colorado Springs; conducted by the Sisters of Charity; medical staff; 80 beds; private.

The Nordrach Ranch, at Colorado Springs; Dr. J. E. White, med. dir.; 50 beds; private.

Emma Booth Tucker Memorial Sanitarium for Consumptives; Salvation Army Tent Colony, at Amity, Prowers Co., Colo.; Dr. Greenard, res. phys.; 100 beds; charitable.

National Jewish Hospital for Consumptives, at Denver; Dr. Moses Collins, supt.; 90 beds; philanthropic.

Y. M. C. A. Health Farm, at Denver; semi-philanthropic; Dr. John Wethered, res. phys.; 45 beds.

Agnes Memorial Sanatorium, at Denver; Dr. G. W. Holden, sec.; 150 beds; semi-philanthropic.

Home for Consumptives, at Denver; Rev. Frederick W. Oakes, supt.; 150 beds; semi-philanthropic.

Resthaven (Home for Consumptives), Park Hill Addition, Denver; Dr. I. S. Garthwaite, president; 50 beds; semi-philanthropic.

Colorado Sanatorium, at Boulder, Colo.; Dr. H. F. Rand, med. supt.; 200 beds; private.

"Foxhall," A Private Home for Pulmonary Invalids; Dr. Wm. N. Beggs, med. dir., 133 West Colfax Ave., Denver; private.

Colorado Tent Colony Sanatorium, at Bennett, Colo.; Dr. W. K. Robinson, phys.-in-chief; 100 beds; private.

Mrs. Lare's Private Sanatorium for Consumptives, 4633 Bert St., Denver; private.

Rocky Mountain Industrial Sanatorium, at Wellington Lake, Denver; Dr. A. M. Holmes, med. dir.; semi-philanthropic.

Ballard Sanatorium, at Pueblo; Mrs. L. B. Wright, matron; 40 beds.

"Tented City," Under Auspices of the Jewish Consumptives' Relief Society, near Denver; philanthropic; Dr. C. D. Spivak, sec.; 12 beds.

CONNECTICUT.

Gaylord Farm Sanatorium, at Wallingford; Dr. David R. Lyman, med. supt.; 40 beds; semi-philanthropic.

New Canaan Pulmonary Sanatorium, at New Canaan; Dr. M. J. Brooks, phys. in charge; 30 beds; private.

Separate Wards for Tuberculous Prisoners, at Westerfield, Conn

---

[2] At the time of the Fifty-fifth Annual Meeting of the American Medical Association, at Atlantic City, N. J., June, 1904.

DISTRICT OF COLUMBIA.

State Hospital for Consumptives, at Hartford; public.

Tuberculosis Division of Government Hospital for the Insane, at Washington, D. C.; Dr. Wm. A. White, supt.; 70 beds.

Washington Asylum Hospital, Tent Wards for Consumptives; Dr. D. Percy Hickling, phys.; Washington, D. C.; 34 beds.

DELAWARE.

Division for Tuberculous Patients at State Hospital for the Insane; Dr. Wm. H. Hancker, supt., Farnhurst, Del.; public.

FLORIDA.

Naval Hospital; Tuberculosis Camp, at Pensacola, Fla.; 50 beds.

HAWAII.

Honolulu Home for Incurables; Dr. A. H. Sinclair, med. supt.; 24 beds; semi-philanthropic.

ILLINOIS.

The Alexian Brothers' Hospital—Consumptives' Ward, Chicago; semi-philanthropic.

St. Anne's Sanatorium for Consumptives, 49th and Thomas Sts., Chicago; Dr. A. F. Kramps, phys.; Sister Superior, supt.; 125 beds; *private*; and 15 free beds.

Cook County Hospital for Consumptives, at Dunning, Ill.; Dr. M. S. McHugh; public; 560 beds.

Illinois Camp *for the* Tuberculous, near Ottawa, Ill.; *under the* Auspices of the Illinois State Med. Soc.; Dr. James W. Pettit, phys. in charge; semi-philanthropic; 40 beds.

INDIANA.

St. Rochus Hospital for Consumptives, West End Main St., Fort Wayne, Ind.

Flower Mission Pavilion, City Hospital, Indianapolis; philanthropic; Dr. P. F. Martin, supt.; 26 beds.

Special Wards for *Tuberculous Prisoners at the* State Reformatory at Indianapolis; Dr. H. C. Sharp, phys. in charge.

IOWA.

Boulder Lodge Sanatorium for Tuberculosis, at Fort Dodge; Dr. John W. Kime, phys.-in-chief; 20 beds; private.

KENTUCKY.

Separate Wards for Tuberculous Prisoners at the Prison Hospital, at Frankfort, Ky.; 20 beds.

LOUISIANA.

Dr. G. R. Tolson's Private Sanatorium, at Covington, La.; private.

Separate Pavilion for Tuberculous Patients of the State Insane Asylum, at Jackson, La.; Dr. Geo. A. B. Hays, supt.; 32 beds.

MAINE.

The Maine Sanatorium, at Greenwood Mountain, near Hebron, Me.; Dr. Estes Nichols, med [illegible] beds, semi philanthropic.

MARYLAND.

Eudowood Sanatorium, Hospital for Consumptives of Maryland, near Towson, Md.; Dr. Harry P. Jarrett, res. phys.; 31 beds; philanthropic.

Bay View Asylum Hospital, Baltimore; Dr. W. H. Smith, phys.; Rev. L. F. Zinkham, supt.; 250 beds; public.

Tents for Tuberculous Patients of the Springfield State Hospital for the Insane, at Sykesville, Md.; Dr. J. C. Clark, supt.

MASSACHUSETTS.

Almshouse Hospital, *at Boston*; *public*; Dr. S. F. Cox, res. phys.; 60 beds.

Channing Home, 30 McLean St., Boston; Mrs. C. P. Fennel, supt.; 17 beds; philanthropic.

House of the Good Samaritan, 6 McLean St., Boston; Miss F. A. Jack, *supt.*; 27 beds.

Sharon Sanatorium, at Sharon, Mass.; Dr. V. Y. Bowditch, phys.-in-chief; 21 beds; semi-philanthropic.

Cullis Home for Consumptives, Blue Hill Ave., Dorchester, Mass.; Rev. E. D. Mallory, supt.; 40 beds.

Free Home for *Consumptives, 428 Quincy St., Dorchester, Mass.*; Jeanette Campbell, supt.; 30 beds; philanthropic.

The Millet Sanatorium, at East Bridgewater, Mass.; Dr. C. S. Millet, phys.-in-chief; 20 beds; private.

Massachusetts State Sanatorium, at Rutland, Mass.; Dr. Walter J. *Marclay*, supt.; public; *250 beds*.

Boston Children's Hospital, Tuberculosis division at Wellesley Hills; 12 beds (including surgical cases).

Private Sanatorium of Dr. David P. Butler, at Rutland, Mass.

State Hospital, at Tewkesbury, Mass.; Dr. John H. Nichols, supt.; 100 beds; public.

Holy Ghost Hospital for Incurables, at Cambridge, Mass.; Sister A. M. Purcell, supt.; 35 beds; private.

MICHIGAN.

Wayne County Hospital, at Eloise, Mich.; tents for 30 tuberculous patients; public; Dr. R. H. Earle, res. phys.

MINNESOTA.

Luther Hospital, at St. Paul, Minn.; Dr. H. G. Steeb, manager; 100 beds.

State Sanatorium *for Consumptives*, at Walker, Cass Co., Minn.

Special Wards for Tuberculous Prisoners, at the State Prison at Stillwater, Minn.

MISSISSIPPI.

Special Hospital for the Tuberculous Insane, at Jackson, Miss.; Dr. T. J. Mitchell, supt.; 40 beds.

MISSOURI.

Mount St. Rose Throat and Chest Hospital, 9200 S. Broadway, St. Louis; conducted by Sisters of St. *Mary*; *Dr. Wm.* Porter, phys.; 100 beds; philanthropic.

Emergency City Hospital, No. 2, St. Louis; Dr. J. Y. *Brown*, res. phys.; 34 beds.

NEBRASKA.

Green Gables, Lincoln, Neb.; Dr. Benjamin F. Bailey, 53d and South Sts.; 35 beds.

NEW HAMPSHIRE.

Pembroke Sanatorium for Consumptives, at Concord, N. H.; Dr. H. T. Fontaine, phys.; 35 beds; private.

White Mountain Tuberculosis Sanatorium, at *North* Conway, N. H.; Dr. S. Dryden Snow, phys.; Clifton J. Bailey, supt.; 50 beds; philanthropic.

NEW JERSEY.

Memorial Hospital, at Orange, N. J.; Mary I. Chambers, supt.; special building for tuberculous patients; 18 beds.

State Sanatorium, at Glen Gardner, Hunterdon Co., N. J.

NEW MEXICO.

St. Joseph's Sanitarium, at Albuquerque; conducted by Sisters of Charity; 100 beds; private.

Chico Springs Sanatorium; Dr. H. B. Masten, med. supt.; 25 beds; private.

St. Antony's Sanatorium, at East Las Vegas; conducted by Sisters of Charity; 32 beds; semi-philanthropic.

"The Montezuma," at Las Vegas Hot Springs, N. Mex.; Dr. J. W. Coon, res. phys.; 200 beds.

St. Vincent's Sanatorium, at Santa Fe; conducted by Sisters of Charity; 28 rooms; semi-philanthropic; Dr. J. Massie, res. phys.

Sun Mount Tent City ("for lung troubles only"), at Santa Fe; Dr. W. M. Popplewell, phys.-in-chief; private.

St. Joseph Sanatorium, at Silver City; Dr. E. S. Bullock, med. dir.; private; 50 beds.

Pines Cottages, at Silver City; T. S. Parker, propr.; private.

The Alameda, at Las Cruces, N. Mex.; 40 beds; private.

The Las Cruces Sanatorium, at Las Cruces; Dr. R. E. McBride, supt.; private; 40 beds.

General Hospital for Soldiers of U. S. Army, at Fort Bayard; *Lt.-Col. E. T. Comegys, Deputy Surg.-Gen.* U. S. A., phys.; 300 beds.

U. S. Public Health and Marine Hospital Service Sanatorium, at Fort Stanton, N. Mex.; Surgeon P. M. Carrington in command; 225 beds.

NEW YORK.

Montefiore Home Country Sanatorium, at Bedford Station, N. Y.; Dr. L. Rosenberg, supt.; 160 beds; philanthropic.

Sanatorium Gabriels, at Gabriels, near Paul Smith's, N. Y.; Sister Mary of Mercy, supt.; R. L. Strong, house phys.; 100 beds; Drs. S. A. Knopf and J. J. Walsh, cons. phys.; semi-philanthropic.

Stony Wold Sanatorium (for Incipient Tuberculosis in Women and Children), at Lake Kushaqua, Franklin Co., N. Y.; Dr. H. S. *Goodall, phys.-in-charge; semi-philanthropic; 150 beds.*

Loomis Sanatorium, at Liberty, N. Y.; Dr. Herbert M. King, phys.; 100 beds; private and semi-philanthropic.

The Edgemont, at Liberty, N. Y.; private.

"Mountain Sanatorium," at Binghamton, N. Y.; Miss Grace C. *Wagner, supt.*; public.

State Hospital for the Insane, at Binghampton, N. Y.; special pavilion for the tuberculous; 100 beds.

Erie County Hospital, tuberculosis wards, at Buffalo; Dr. E. J. Gilray, phys.; 54 beds; public.

Buffalo State Hospital, at Forest Ave., Buffalo; Dr. Arthur W. Hurd, med. supt.; tuberculosis wards; public.

Hospital for Incipient Tuberculosis, *at Rochester, N. Y.*; Dr. G. W. Coler, phys. in charge; 40 beds; semi-public.

State Hospital for Incipient Tuberculosis, at Raybrook, Franklin Co., N. Y.; Dr. John H. Pryor, phys.; $5.00 per week; 120 beds.

Adirondack Cottage Sanatorium, at Saranac Lake, N. Y.; Dr. E. L. Trudeau, phys.-in charge; Dr. Lawrason Brown, res. phys.; 100 beds; semi-philanthropic.

Reception Cottage, at Saranac Lake, N. Y.; Dr. E. R. Baldwin, phys.; semi-philanthropic; 15 beds.

Raymond Cottage, at Saranac Lake; in charge of Mrs. Josephine R. Raymond; Dr. E. R. Baldwin, phys.; 14 beds.

Rumanapp Cottage, at Saranac Lake; in charge of Miss Rumanapp; Dr. Lawrason Brown, phys.; 20 beds.

Hill Crest, at Santa Clara, Franklin Co., N. Y.; for working girls and women; Dr. Caroline M. Hengel, res. phys.; 56 beds; private.

Springside Sanitarium, at Auburn, N. Y.; Dr. Nettie E. Jenkins, *res. phys.*; 15 beds; private.

All Saints' Home, at Verkank, Duchess Co., N. Y.; Pavilion for Tuberculous Patients; in charge of the Brothers of Nazareth; 10 beds.

Westchester County Hospital (Pavilion for Consumptives); Dr. Fred'k Baker, house phys.; 24 beds; public.

Brooklyn Home for Consumptives, 240 Kingston Ave., Brooklyn; Dr. E. Reynolds, phys.; Elizabeth A. Doyle, supt.; 120 beds; semi-philanthropic.

Seton Hospital, at Spuyten Duyvil, New York City; Dr. B. B. Steedly, phys.; 200 beds; semi-philanthropic.

St. Joseph's Hospital for Consumptives, East 143d St., New York City; Dr. *Charles* M. Cauldwell, phys.-in-chief; 350 beds; semi-philanthropic.

The House of Rest for Consumptives, Bolton Road and 209th St., New York City; George Sauer, supt.; philanthropic; 39 beds.

St. Peter's Hospital, at Henry, Congress and Warren Sts., New York City; *Five Wards Reserved for Consumptives*; conducted by the Sisters of the Poor of St. Francis; Dr. T. P. Corbally, phys. in charge; 75 beds; philanthropic.

Home for Incurables, Third Ave. and 181st St., New York City; Dr. Israel C. Jones, supt.; 275 beds; tuberculosis wards.

New York Postgraduate Hospital Annex for the Treatment of Tuberculosis (for poor patients only), at 322 E. 10th St., New York City; Dr. John F. Russell, *phys.* in charge; 12 beds; philanthropic.

Kings County Hospital Infirmary, Clarkson St., New York City; tuberculosis wards; Dr. F. W. Smith, res. phys.; 65 beds.

Montefiore Home (Ward for Consumptives), Broadway and 138th St., New York City; Dr. S. Wachsmann, phys.; A. Hausmann, supt.; philanthropic; 40 beds.

The Riverside Sanatorium for Pulmonary Diseases; Health Dept. *of the* City *of* New York, at North Brother Island; Drs. S. A. Knopf, W. J. Pulley and John H. Huddleston, visit. phys.; Dr. Samuel T. Watson, res. *phys.*; 60 beds; public; free.

Lincoln Hospital and Home (Tuberculosis Ward), 141st St. and South Boulevard, New York City; Amzi Lake, supt.; for *colored; free;* 40 beds.

Manhattan State Hospital East for the *Insane*, at Wards Island, New York City; Dr. A. E. McDonald, supt.; tuberculosis division.

Tent Colony for Tuberculous Men and Women *of the* Willard State Hospital for the Insane, at Willard, Seneca Co., N. Y.; Dr. Robert M. Elliott, supt.

County Hospital (Tuberculosis Ward), East View, Yonkers, N. Y.; public.

Phthisis Infirmary of the Metropolitan Hospital, at Blackwells Island, New York City; under homeopathic management; public; free; Dr. J. B. Mickle, chief of med. staff; 450 beds.

Seaside Tent Sanatorium for Scrofulous and Tuberculous Children of the Society for Improving the Condition of the Poor, at Seabreeze, Coney Island, N. Y.; Dr. M. Burnham, res. phys.; philanthropic; 54 beds.

Wards for Tuberculous Prisoners of Clinton Prison, at the Dannemora State Hospital, Dannemora, N. Y.; Dr. J. B. Ransom, med. officer.

NORTH CAROLINA.

The Winyah Sanitarium, at Asheville, N. C.; Dr. Karl von Ruck, med. director; 70 beds; private.

Southern Pines Sanitarium, at Southern Pines, N. C.; Dr. Edwin Gladmon, phys.; 30 beds; private.

Pineshire Sanitarium, at Southern Pines; Dr. L. F. High, phys.; 25 beds; private.

Franklin Humanitarian Home, at Black Mountain, N. C.; philanthropic; 12 beds.

St. Joseph's Sanatorium, at Asheville; conducted by the Sisters of Mercy; 25 beds; private.

Dr. Stevens' Home for Incipient Tuberculous Patients, at Asheville, N. C.; Dr. Martin L. Stevens; 8 beds; private.

Dr. Dunn's Sanitarium for Diseases of Throat and Lungs, Sunny Side, Sunset Mountain, Asheville, N. C.; private.

NORTH DAKOTA.

Oakpark Sanatorium for Consumptives, at Minot, N. D.; Dr. V. Mohn, phys.; 25 beds; private.

OHIO.

Cincinnati Branch Hospital for Consumptives, Cincinnati, Ohio; public; Dr. B. F. Lyle, phys.; 120 beds.

Municipal Tuberculosis Sanatorium, at Cleveland, Ohio; Dr. J. C. Placak, res. phys.; F. C. Emde, supt.; 75 beds; public.

Miami Valley Hospital, at Dayton, Ohio; Ella P. Crandall, supt.; tuberculosis division.

Western Hill Hospital and Sanatorium, at Price Hill, Cincinnati; Dr. Oswald Katz, res. phys.; 30 beds; semi-philanthropic.

PENNSYLVANIA.

West Mountain Consumptive Hospital, at Scranton; philanthropic. Dr. J. M. Wainwright, phys., 26 beds.

South Mountain Camp Sanitarium, at Mt. Alto, Franklin Co., Pa.; Major Oliver B. Simmons in charge.

Bide-Awhile Sanatorium, at Perkiomenville, Pa.

Tent Camp for Tuberculosis Patients of the Columbus State Hospital for the Insane; 100 beds.

Mt. Jefferson Sanatorium at Lansford (Summit Hill P. O.), Pa.; Dr. W. H. Clewell, res. phys.; 25 beds; private.

Private Sanatorium of Drs. J. T. and A. M. Rothrock, at Mont Alto, Franklin Co., Pa.; 10 beds.

The Darmady Sanatorium at Mt. Airy, Philadelphia, Pa.; Miss Margaret G. O'Hara, matron; 25 beds; private.

Sunnyrest Sanatorium, at White Haven, Pa.; Elwell Stockdale, supt.; L. F. Flick, Joseph Walsh and William Stanton, vis. phys.; 50 beds; private.

White Haven Sanatorium of the Free Hospital for Poor Consumptives, at White Haven, Pa.; Drs. Shoemaker and Heller, phys.; Dr. Jas. H. Heller, supt.; 126 beds; philanthropic.

Switch Back Sanatorium, at Lansford, Pa.

Kane Summit Hospital, at Kane, Pa.; Mary J. Hayes, supt.; 50 beds.

Chestnut Hill Hospital for Female Consumptives, at Philadelphia; Dr. A. L. Bacon, res. phys.; Rev. H. L. Duhring, supt.; 65 beds; philanthropic.

House of Mercy for Male Consumptives, 411 Spruce St., Philadelphia; Dr. W. M. Agney, house phys.; Rev. H. L. Duhring, supt.; 12 beds; philanthropic.

Philadelphia Hospital (Wards for Consumptives), Thirty-fourth and Pine Sts., Philadelphia; Dr. M. H. Briggs, chief res. phys.; 174 beds; public.

Rush Hospital for Consumptives, 44 W. 33d St., Philadelphia; Elizabeth M. Brophy, supt.; 60 beds; philanthropic.

Henry Phipps Institute Hospital, 238 Pine St., Philadelphia; Lawrence F. Flick, phys.-in-chief; Mary Mahoney, supt.; 52 beds; philanthropic.

Free Tuberculosis Hospital for Consumptives of Pittsburg and Allegheny, 253 Shady Ave., Pittsburg, Pa.; Dr. Henry N. Hall, phys.; 50 beds; philanthropic.

Tent Camp in the Pocono Mountains for the Treatment of Consumption, at Greentown, Pike Co., Pa.; Dr. Albert S. Ashmead, phys.; private.

Lucien Moss Home of Jewish Hospital, at Philadelphia; Dr. Edwin D. Jareckey, res. phys.; 31 beds; philanthropic.

Reading Sanatorium for Tuberculosis, at Reading, Pa.

RHODE ISLAND.

St. Joseph's Hospital, at Providence; Wards for Consumptives; Sister Superior, supt.; Dr. Wm. Hindle, res. phys.; philanthropic; 24 beds.

Pine Ridge Camp for [illegible] at Foster, R. I.; Dr. W. H. Peters, phys.; [illegible] beds.

State Sanato[illegible]; 100 beds.

State Almshouse, Tuberculosis Division, at Howard, R. I.; Dr. Geo. F. Keene, phys. in charge; 40 beds.

Tuberculosis Division of the State Hospital for the Insane, at Howard, R. I.; Dr. George F. Keene, supt.

SOUTH CAROLINA.

Aiken Cottage Sanatorium, at Aiken, S. C.; Dr. C. F. McGahan, phys.; 15 beds; semi-philanthropic.

Separate Building for Tuberculous Prisoners of the State Penitentiary, at Columbia, S. C.; Dr. D. J. Griffith, supt.; 50 beds.

TEXAS.

Camp Reliance, at Comfort, Texas; Dr. C. H. Wilkinson; private.

Wynne Farm Agricultural Colony for Tuberculous Prisoners, at Huntsville, Texas; Dr. W. E. Fowler.

White Gables, S. W. Texas Sanitarium, at Boerne, Kendall Co., Texas.

Sisters' Hospital, Hotel Dieu, at El Paso, Texa.; Tuberculosis Wing, 50 beds; conducted by the Sisters of Charity.

Dr. L. W. Cook's Sanatorium, at Boerne, Texas; private.

Dr. Briggs' Private Sanatorium for Diseases of Throat and Lungs, at Dallas, Texas; Dr. J. R. Briggs, phys.; 60 beds; private.

VERMONT.

The Champlain Open air Sanitarium, at South Hero, Vt.; Dr. H. D. Lewis, med. dir.; 30 beds; private.

Ward for Tuberculous Patients of the Vermont State Hospital for the Insane, at Waterbury, Vt.; Dr. M. Hutchinson, supt.; 22 beds.

VIRGINIA.

Camp for Tuberculous Patients of the Central State Hospital for the Insane, at Petersburg, Va.; Dr. Wm. T. Drewry, supt.; 70 beds.

WASHINGTON.

King County Hospital, at Seattle, Wash.; tuberculosis wards; 15 beds; Dr. Wm. T. O'Rourke, supt.; public.

WISCONSIN.

Evergreen Park Cottage Sanatorium, at Lake Nebagamon, Wis.; Dr. W. B. Hopkins, med. dir.; private; 15 beds.

Wisconsin Dells Sanatorium, at Kilbourn, Wis.

The Wisconsin Health Park Association, at Tomahawk, Lincoln Co.; Dr. W. T. Roberts, field secretary.

CANADA.

Free Home for Consumptives, at Gravenhurst, Ont.; Dr. Chas. D. Parfitt, phys. in charge; 75 beds; philanthropic.

Muskoka Cottage Sanatorium, at Gravenhurst, Ont.; Dr. J. H. Elliott, phys. in charge; 75 beds; semi-philanthropic.

Toronto New Consumption Hospital of the National Sanitarium Association, near Toronto, Ont.; Dr. Allan H. Adams, phys.; philanthropic.

Lhal Ghur Private Sanatorium, at Ste. Agathe des Monts, Quebec; Dr. Howard D. Kemp, phys. in charge; 16 beds.

Montreal Sanatorium for Consumptives, at Montreal, Quebec.

Provincial Sanatorium for Consumptives, at Montreal, Quebec.

Wolfville Highlands Sanatorium, Nova Scotia.—Dr. G. E. DeWitt, med. dir.; 8 beds; private.

LIST OF DISPENSARIES AND CLINICS FOR PULMONARY TUBERCULOSIS.

CONNECTICUT.

New Haven Dispensary Tuberculosis Clinic, Congress Ave., New Haven, Conn.; Dr. H. M. Steele, phys. in charge.

ILLINOIS.

Dispensaries of the Committee on the Prevention of Tuberculosis of the Visiting Nurses' Association, 79 Dearborn St., Chicago, Ill.; Dr. Arnold C. Klebs, med. dir.

MARYLAND.

Out-patient Department, Johns Hopkins Hospital, Baltimore, Md.

DISTRICT OF COLUMBIA.

Tuberculosis Dispensary, 605 4½ St. S. W., Washington, D. C.

MASSACHUSETTS.

Boston Dispensary, at Bennet and Ash Sts., Boston, Mass.; Dr. Edward O. Otis, supt.

Tuberculosis Clinic—twice a week—at City Hospital, Worcester, Mass.; Dr. Albert C. Gotshell, phys. in charge.

MINNESOTA.

Hamlin University Free Dispensary, at Minneapolis; Dr. G. G. Poehler, phys. in charge.

State University Free Tuberculosis Dispensary, S. Washington Ave., Minneapolis; Dr. Henry L. Ulrich, phys. in charge.

NEW JERSEY.

Orange Memorial Hospital Dispensary, at Orange, N. J.; Dr. Henry A. Tulsford, phys. in charge.

NEW YORK.

Gouverneur Hospital Dispensary, Front St., New York City; Drs. Gilbert and Bradford in charge.

Clinic for Pulmonary Diseases of the Health Department of New York City, at 6th Ave. and 55th St.; Dr. Herm. M. Biggs, director; Drs. J. S. Billings, Jr., and S. A. Knopf, assoc. directors.

Special Classes at the Vanderbilt Clinic for the Treatment of Tuberculosis; Dr. Linsey R. Williams, phys.

Special Classes at Bellevue Hospital Dispensary; Dr. James Alexander Miller, phys.

New York Postgraduate Hospital Dispensary (Dr. Russell's Classes).

Dispensary for Consumptive Poor of the New York Throat, Nose and Lung Hospital, 59th St., near 2d Ave.; Drs. Birmingham, Barton, Goldstein and Wheeler, phys.

Presbyterian Hospital Dispensary, New York City.

Harlem Hospital Dispensary, Foot of East 120th St., New York City; Dr. Charles H. Moak, phys. in charge.

OHIO.

Tuberculosis Dispensary of the Western Reserve University, at Cleveland, Ohio; Dr. T. H. Lowman, phys. in charge.

PENNSYLVANIA.

Tuberculosis Dispensary of the Scranton Society for the Prevention and Cure of Consumption, 203 Linden St., Scranton, Pa.

Henry Phipps Institute Dispensary, 238 Pine St., Philadelphia.

Rush Hospital Dispensary, Lancaster Ave. and Thirty-third St., Philadelphia; Dr. John D. McLean.

Dispensary of the White League, 1515 Arch St., Philadelphia; Dr. Joseph P. Craney, phys.

RHODE ISLAND.

Out-patient Department of the Rhode Island Hospital, at Providence; Dr. Jay Perkins, supt.

I hope that the foregoing list is a complete one, and still the possibility of errors of omission and commission exists. Worthy institutions may have been established since of which I have not heard, and thus they may have been inadvertently omitted; some institutions may have been reported to me as sanatoria, taking care of tuberculous cases exclusively, while in reality they are sanitaria or homes where all classes of patients are received. If these are mentioned in my list, they ought not to have been included. In this list we read the names sanatorium, sanitarium, hospital, home, etc. This brings me to a subject of which I like to speak in connection with the designation or naming of institutions consecrated to the exclusive treatment of tuberculous invalids.

The proper designation for an institution which receives patients afflicted with pulmonary or laryngeal tuberculosis only is, in my humble opinion, sanatorium. May I be permitted to state why I prefer the word sanatorium to sanitarium? Brehmer, the founder of the first institution of that kind, called it *Heilanstalt,* which means healing institution; and the word "sanatorium," from the Latin *sanare,* to heal, gives certainly a better equivalent for the German word than the word "sanitarium." This latter word is derived from the Latin, *sanitas,* health, and is usually employed in this country to designate a place considered as especially healthy, a favorite resort for convalescent patients, or an institution for the treatment of mental or nervous diseases. It is well and useful from all points of view to make a distinction that the special uses and purposes of the tuberculosis institution may be understood readily.

The word "sanitorium," so frequently used, is simply incorrect. May I say in addition that the word sanatorium has been adopted as an official name by the United States Government for the institutions for its consumptive sailors and soldiers; also that the name of the Massachusetts state institution is sanatorium and not sanitarium, and that the former Loomis Sanitarium has been changed to Loomis Sanatorium, Sharon Sanitarium to Sharon Sanatorium, and that all the more recently established institutions for the exclusive treatment of tuberculous patients in this country, Canada and England have adopted the name sanatorium? As mentioned above, Germany calls these institutions *Heilanstalten,* and all other European nations call institutions of that kind sanatoria.

Special hospitals for the treatment of the tuberculous patients are particularly useful institutions because they are, as a rule, located in or very near large centers of population. They are supposed to receive the more advanced and hopeless cases which in their home environment can not or do not receive the necessary care, and often constitute centers of infection. Of the value of such institutions I can not speak too highly, and personal experience at the Riverside institution of the health department of the City of New York has made me quite enthusiastic over the work which can be done in such establishments. This institution, which we call Riverside Sanatorium, located on North Brother Island, opposite East 138th St., was established on the urgent appeals of Dr. Herman M. Biggs, the general medical officer and his colleagues of the board of health. Thanks to a law, which I believe exists only in New York, and which Dr. Biggs promulgated, we have in New York a right to remove any tuberculous patient from his home to one of the city tuberculosis institutions if in the opinion of the medical inspector the patient constitutes a danger to his environment.

The results obtained with these patients forcibly removed from their unhygienic surroundings to our Riverside Sanatorium, which is of course only a city sanatorium, is surprising. It is very often one of the hardest things to induce patients to leave the institution, when, in our opinion, the disease has been sufficiently arrested and warrants the discharge of the patient. The clean, sanitary surroundings, the regular mode of life, and the personal interest which is taken in every case, makes most of these patients become attached to the institution, and the prospect of being obliged to return to unsanitary environments and other former unpleasant conditions is the cause of their disinclination to leave.

The difficult problem of what to do with the cured consumptive, of which I will speak later on, has never come to me with more seriousness than when I am about to discharge a patient from the Riverside Sanatorium. Yet I would suggest that the law which gives our health department the right to forcibly remove to a special tuberculosis institution a patient who plainly constitutes a danger to his environment, is a wise one and well worth trying in other large American cities. Even if we are not able, for the present, to provide work for all our discharged consumptives (we strive to give employment to as many as possible as helpers and orderlies), the training they have received and the orderly life they have been forced to live, will rarely fail to leave its impression. I can modestly claim that a goodly number of the men and women sent out from the health department's institution at North Brother Island, whether cured or only improved, on their return to their former homes constitute themselves missionaries and hygienic examples among the members of their families, their neighbors and friends.

The "Homes for Consumptives" I have never liked, for, from my experience of a visit to a number of them I gained the impression that the so important hygienic and sanitary measures in these institutions are never so rigidly adhered to as in sanatoria and special hospitals. There are, as a rule, fewer nurses and fewer attendants, and herein, I believe, lies the mistake, for if the patient ever needs the constant care of a watchful nurse it is in the last stages of the disease. Now, the word "Home" indicates that the unfortunate consumptive will remain there until his dissolution. This is another important reason why I do not like the word "Home." I am convinced many enter the home for consumptives who before were perhaps full of hopes for a recovery, and many even enter it in a condition when recovery would seem possible. Why may we not just as well call every home a sanatorium and make it such? This is what it should be—a sanatorium—a healing institution.

The next class of institutions which we wish to speak of are seaside sanatoria for tuberculous and scrofulous children. I have only a single one on my list; they are worth our consideration. Seaside sanatoria for scrofulous and tuberculous children serve to take care, throughout the whole year, of children afflicted with joint, osseous and cutaneous tuberculous troubles, and all children afflicted with milder manifestations of tuberculous character, generally designated as scrofulosis. Another important factor of such seaside sanatoria is to attend to the after-treatment of children operated on for tuberculous joint troubles in the city, and to keep them during their convalescing stage. It was my privilege to serve for some time as assistant to such an institution in France. There, in the celebrated institution at Berck-sur-Mer, belonging to the city of Paris, we received weekly from ten to twenty-five little ones who had been operated on. The change which was wrought in the faces of these children after a few weeks' sojourn at the seaside was something hard to believe. These pale-faced; underfed children, coming mainly from the homes of the poor of Paris, became rosy-cheeked and healthy looking youngsters in the ozone-laden atmosphere of the sea coast. A school with a number of teachers is attached to that institution so that the intellectual development of the children may not suffer during their sojourn in the sanatorium. I trust that the example given by the New York Society for improving the Condition of the Poor in the creation of such an institution at Seabreeze near New York, will find numerous imitators among the philanthropists and municipalities of our country.

It must be evident to every physician and sanitarian that multiple sanatoria for the treatment and care of tuberculous children is one of the most important factors in the fight against consumption. The child thoroughly cured from its tuberculous affliction by the best of surgical, orthopedic, hygienic, dietetic and climatic treatment is not likely to become a consumptive adult, while every child with a neglected local tuberculosis must always be considered a candidate for consumption.

Pulmonary tuberculosis is relatively rare in little ones, but even for those few, I am happy to say, we have some provisions in the State of New York. As you will have noticed in my statistics, the Seton Hospital as well as the Loomis Sanatorium, have made special provisions to treat children suffering from pulmonary tuberculosis.

The next kind of institution to be considered as an important factor toward the solution of the tuberculosis problem is the special tuberculosis dispensary. As a definition of this institution permit me to use here the same words which I used as introductory remarks in my address recently delivered before the New York Academy of Medicine to open the discussion at a symposium on special tuberculous dispensaries ,

A modern tuberculosis dispensary is an institution created, built, equipped and managed for the exclusive treatment of indigent persons afflicted with pulmonary or laryngeal tuberculosis. The modern conception of the treatment and management of ambulatory tuberculous cases demands the creation of such institutions. Those of us who began our medical career fifteen or twenty years ago will remember the almost universal indifference of our teachers as well as ourselves when in our dispensary practice we came across a tuberculous case. The sooner we could dispose of it the better we thought we did our duty. Some cough mixture and some cod-liver oil was the routine treatment. There was no time. nor did we think it necessary, to teach the patient to take any precaution with his infectious sputum, or to give him any other hygienic instruction. The value of breathing exercises in such cases was thought of by but few.

How different is it to-day. To avoid as far as practicable the contact of the tuberculous patient with other patients, separate classes are created in many of our general dispensaries; but the ideal, of course, must always be the entirely separate and especially constructed tuberculosis dispensary.

Besides the institution with which I have the honor of being connected, and which, to the best of my knowledge, is the first municipal dispensary especially built for that purpose in the United States, there are at this moment in New York six other dispensaries which have special classes for tuberculous cases. From my list you will see that Boston, Baltimore, Philadelphia, New Haven, Scranton, Minneapolis, Chicago, Worcester and Providence are the other cities in the United States which have thus far created special tuberculosis dispensaries.

The setting aside of a ward for tuberculous patients in a general hospital, an insane asylum or prison seems to me, while not nearly as good as a sanatorium, special hospital or special camp, the next best thing to it. Quite satisfactory results can often be obtained when in a general hospital the best ventilated and best lighted ward—which is usually the upper story—can be used for that purpose. The results in a special tuberculosis ward at a general hospital can be enhanced when there is a roof garden in connection with the ward, and outdoor life and outdoor sleeping can thus be inaugurated in the city. This is very desirable during hot weather, and in connection with it I would suggest that on the top of nearly every hospital a roof garden can be improvised with a covering of canvas to which are attached side flaps when protection from sun and rain is necessary; with a few flowers and shrubs here and there this improvised roof garden can be made very attractive, and the whole installation accomplished with relatively little expense.

By an exhaustive inquiry, previous to the publication of my article, "A Plea for Justice to the Consumptive," I learned from authorities well qualified to speak on this subject that tuberculosis more frequently follows the development of insanity than precedes it. Or, if I may use here the words of Prof. Edward D. Fisher, who kindly wrote me at the time: "Tuberculosis is more common in the insane as a result of lowered vital condition than as a cause of the mental disease." When the insane individual, with a thus lowered vital condition, comes in close prolonged contact with another insane person who is tuberculous, is it a wonder when a non-tuberculous insane person in an overcrowded insane asylum contracts tuberculosis?

That something can be done for even the insane tuberculous patient, that all can be isolated and a number of them cured of both their physical and mental infirmities, has been beautifully demonstrated by the tent life inaugurated by Dr. McDonald and his associates at the Manhattan State Hospital for the Insane on Ward's Island.

Concerning tuberculosis in prisons, I wish to speak with particular emphasis, for while here and there provisions for the treatment of tuberculous prisoners have been made, there is still much and urgent work in this direction before our public sanitarians and the managers of prisons and reformatories in many of the states of the Union. For the good of society we must confine the criminal and punish him, and above all, we seek to reform him by years of seclusion, according to the gravity of his offense. But however great the crime he may have committed, we have no right to sentence him to contracting tuberculosis, which, as prison life is now in many of our states, must almost invariably result in death. The best solution of the tuberculosis problem in regard to prisons is, to my mind, that which has been successfully tried by the Texas Agricultural Colony for Tuberculous Prisoners. Instead of letting them linger and suffer in isolation and die in degradation, the Agricultural Colony of Texas strives to make of its tuberculous prisoners useful and healthy members of society. It is always a pleasure to note that the most humane undertakings are blessed with financial success; $25,000 remained as net earnings during the first year of the existence of the Texas Agricultural Colony for Tuberculous Prisoners. May the example of this state lead to the establishment of many such colonies.

My suggestions for the establishment of agricultural and horticultural colonies are, however, not only intended for tuberculous prisoners. I plead with equal emphasis for the establishment of such for the honest tuberculous patients who have faithfully passed through the schooling in a sanatorium; who have learned to prevent infecting others or reinfecting themselves; who leave the sanatorium virtually cured, but by no means strong enough to take up the old occupations which, in many instances, had rendered them tuberculous. It is a grave and serious problem what to do with the cured tuberculous patient, who was formerly a stone cutter, a printer, a tailor or a hat maker, etc. Shall we return him to his former unhygienic occupation—to his insanitary work or sweat shop? The time and money expended for sanatorium treatment would have been spent in vain if these toilers must return to the same environments. It is a medical, social and financial problem, and those who provide sanitary occupation for cured consumptives so that they may live and labor after their restoration to health and remain well, will do as much for the solution of the tuberculosis problem as the founders of sanatoria and special hospitals.

This report on the antituberculosis work done during the last few years would indeed be incomplete without mentioning the first tuberculosis exposition in the United States, held in Baltimore from Jan. 25 to Feb. 1, 1904. From a local attempt to give the people of Maryland an object lesson in the prevention of tuberculosis, this exposition grew to be a national enterprise, an educational center of the history, distribution, variation, causes, cost, prevention and cure of tuberculosis.

The exposition was held under the auspices of the Tuberculosis Commission of Maryland conjointly with the board of health of the same state and the Maryland Public Health Association. There were exhibits from all parts of the United States, from Canada and from other foreign countries. The exposition was divided into numerous divisions, one of the most instructive being the statistical section. Mortality and morbidity of tuberculosis and their relation to race, age, sex, occupation, heredity, marriage, topography and geography were graphically demonstrated. The charts exhibited by the Prudential Life Insurance Company, showing the variations of the occurrence of tuberculosis in different races, sexes and classes of people, were particularly interesting. A large map had been prepared by the Baltimore health board, showing all the houses in which there has been a death from tuberculosis in the ten years from 1890 to 1900. Each of these 11,582 deaths was indicated by a red dot; the worst area, consisting of ten squares crowded with negroes, showed 175 deaths. Another section of the exhibit showed sanitary and insanitary tenements, factories and workshops. Pictures of "lung blocks," that is to say, buildings which are particularly infected by tuberculosis, were shown from the city of New York and Baltimore. They taught a fearful object lesson of overcrowding, filth, lack of air and light.

The committees for the prevention of tuberculosis of New York, Chicago, Boston and Baltimore showed by statistics, literature and photographs the work they had accomplished independently of municipal aid. Nearly all the states of the Union and the provinces of Canada, where state and municipal health boards are engaged in the prevention of tuberculosis, sent charts, drawings and pictures, showing their really surprising activity during the last few years. New York City took the lead by showing a reduction in the mortality from tuberculosis by one-third of what it was ten years ago. The health department of New York City also exhibited its celebrated "Circular of Instruction to Consumptives and Those Living with Them," besides photographs of its Riverside Sanatorium and the new Clinic for Pulmonary Diseases.

The directors of nearly all the American and Canadian sanatoria and special hospitals for the treatment of consumption sent photographs of their institutions. It was my privilege to send my collection of views—German, English, French, Swiss, Scandinavian and Austrian sanatoria, and also the excellent photographs of Brehmer, Dettweiler, Koch and Trudeau. (The latter is the pioneer of the sanatorium treatment in America.)

There were a large number of tents, model cottages, reclining chairs, elevated, fixed, pocket and other kinds of spittoons. Of great interest was the excellent collection of books and portraits sent by Professors Osler and Jacobs. The pathologic exhibit, which owed its existence to Professor Welch of Johns Hopkins Pathologic Department, was unusually interesting. It was visited by many physicians and students. Trained demonstrators were constantly present to explain the pathologic specimens and bacteriologic exhibits. A very unique way of making the exposition a thorough educational center for the laity was arranged by Dr. Fulton. He divided the visitors in groups of twenty or twenty-five, and assigned to each of these one of the young enthusiastic physicians who had volunteered their services as guides and demonstrators. A very important and interesting feature of the exposition was the evening lectures by a number of specialists.

The tuberculosis exposition was an unqualified success. It had not only the support of the best men of the Baltimore medical profession, but His Excellency, the Governor of Maryland, His Honor, the Mayor of Baltimore, and a number of distinguished Baltimore citizens lent their moral and financial support to the success of the undertaking.

A similar exhibition, although on a much smaller scale, took place recently in Boston (October 1904), in connection with the Mechanics Fair. The Association for the Relief and Control of Tuberculosis of Boston had arranged a most creditable and instructive exhibit of things and literature relating to the modern modes of prevention and treatment of tuberculosis. The citizens of Boston and the surrounding country paid unusual attention to the tuberculosis corner. It would seem that such object lessons in the prevention of tuberculosis might well be imitated by other [illegible] cities.

I do not report this time anything concerning laws to combat bovine tuberculosis, nor have I enumerated the special regulations or ordinances issued concerning the prevention of tuberculosis in man. Few changes have occurred since my last report (November, 1902.) I wish to state, however, that an additional number of cities have enacted antispitting laws. Koch's declaration at the last international tuberculosis congress in London, concerning the relative rarity of the transmission of bovine tuberculosis to man, has not influenced American authorities to lessen existing measures to prevent the spread of bovine tuberculosis or its transmission to man; yet there is a great variety in these bovine laws in the different states, and perhaps a greater variety existing concerning the laws and regulations to prevent tuberculosis in man.

As in my previous report, so must I say in this one that a "ministry of health" at Washington, a "United States Board of Health," to be in constant touch with all the state and city boards of health in the Union, with effective laws to combat tuberculosis in man and beast throughout the Union, is the only remedy for the lack of uniformity and effectiveness of antituberculosis laws in this country.

To any one who has studied the tuberculosis problem in its social as well as in its medical aspect, it must be evident that its solution can only be accomplished by effectual co-operation. I have just expressed my views as to how the work of the state and city boards of health could be made more effective by co-operation with a national board of health. The purely medical aspect of the disease will, I know, be intelligently studied by our new organization above referred to; but what I plead for most insistently is that the philanthropists, laymen and physicians, composing the various organizations, commissions and committees, may be in constant co-operation with a "Federal Committee" or permanent "National Bureau for the Prevention of Tuberculosis," to which the new society, I trust, will give the incentive, in order to avoid useless multiplication of work on the one hand, and increase effectiveness of needed work on the other. For example, if two adjoining states find it advantageous to combine in establishing a state sanatorium, let them not hesitate for reason of local pride to carry out the project. A large city may have a dozen associations, commissions or committees on the prevention of tuberculosis. When it comes to establishing an institution, let them be united in the project; and when it comes to taking care of a needy patient, let him be referred to a single subcommittee, whose duty it should be to investigate the case and provide for the patient in such a way as is best for his own interest and that of the community. The philanthropist should not give blindly, but should inform himself first where the need of his help is greatest, for there are many phases in the solution of the tuberculosis problem. While in one city it might be wiser to establish a dispensary for tuberculosis; in another it may be wiser to start a sanatorium, and in another an agricultural colony may be needed; while in others the creation of more playgrounds, parks, public baths and model tenements may be of the greatest importance and the greatest necessity.

The little motto with which I prefaced, some years ago, an essay entitled "Tuberculosis as a Disease of the Masses and How to Combat It," is applicable to-day, and I believe will be as long as there is a tuberculosis problem: "To combat tuberculosis as a disease of the masses successfully requires the combined action of a wise government, well-trained physicians and an intelligent people."

Alcoholic Nostrums Too Strong for Lumbermen.—Loggers in the northern woods seek to discourage the use of patent medicines in their camps, as the "lumber-jack" is inclined to use them as a substitute for alcoholic exhilaration, to the subsequent disturbance of his working powers.—*Northwestern Druggist.*

THE ASSOCIATION OF OPTIC NEURITIS AND FACIAL PARALYSIS.*

EDWARD A. SHUMWAY, B.S., M.D.

PHILADELPHIA.

The relative infrequency with which optic neuritis occurs in association with facial paralysis makes the following case worthy of record:

The Patient.—Miss G. W., age 19, came to the eye dispensary of the University Hospital, Philadelphia, Dec. 8, 1903, in the service of Dr. George E. de Schweinitz, to whose courtesy I am indebted for permission to publish the case. She complained of blurring of print and aching in the eyes in reading or other close work. She was unaware that her eyesight had failed, but examination showed that vision of the right eye was 6/15 and of the left eye only 6/30. She was able to read Jaeger 0.50 D. with each eye at 13 cm. slowly.

Ophthalmoscopic Examination.—There was atrophy of each optic nerve, more advanced on the left side. The nerve heads were covered with a delicate, white tissue, which blurred their edges, and could be traced in the form of white lines along the central vessels of the retina. The veins were of good caliber, but the arteries were reduced to mere threads at the disc, though they were somewhat fuller at a distanc from it. The fundus in each eye was otherwise normal. The picture was, therefore, a typical one of post-papillitic atrophy. The pupils were equal and responded rather sluggishly. The visual fields are shown in the accompanying chart (Fig. 1). They were moderately contracted, both for form and color, but showed no color scotomas. Under reduced illumination O. D. vision was only 6/30, and O. S. 2/60. With de Wecker and Masselon's photometric test the light sense was 4/10 in the right and 1/10 in the left eye. There was in addition a flattening of the right side of the face and a decided enophthalmus on this side.

History.—Careful questioning as to previous history brought out the following facts: She was the youngest of ten children, two of whom died in early childhood, one of diphtheria and the other of "enlargement of the heart." The rest were healthy and had had no eye trouble. She had always been very pale, and suffered from irregular menstruation, the amenorrhea lasting sometimes for several months. She had had measles alone of children's diseases, and no recent acute illness of any kind. On Nov. 1, 1902, she consulted Dr. James E. Talley of Philadelphia for paralysis of the right side of the face, which appeared after exposure to a draught, and was preceded and accompanied by severe pain in the lower jaw and teeth, and in front of the ear, on the same side. Dr. Talley found a typical facial paralysis of the peripheral type, but noted no areas of anesthesia. The face was flaccid, the mouth was drawn to the left and she was unable to close the right eye. There was no ear disease present, but she was very anemic, and gave the history of menstrual disturbance. Blood examination showed red blood corpuscles 4,268,000, white blood corpuscles 5,200, and hemoglobin 90 per cent. Dr. Talley thought the blood examination incorrect, especially as to the percentage of hemoglobin, owing to a defect in the instrument, but she did not return for further examination. The urine was alkaline, specific gravity 1,022, and contained neither albumin nor sugar; microscopically it was negative, except for phosphates.

Treatment.—She was treated with salicylates, strychnia, massage, electricity, and later iron. Three weeks afterward there was some return of motion in the face and the mouth was straighter, but the eye could not be closed. Early in December, 1902, she left the city, and was under the care of Dr. R. P. Heilman of Emporium, Pa., who prescribed iron and general tonic treatment. Dr. Heilman reports that he detected some anesthesia of the right side of the face, but no complaint was made of any disturbance of vision. The patient says, however, that on one occasion, when sent to the library for a book, she was unable to see the title in the poorly lighted room, but aside from this did not have her attention called to her eyes, which were neither painful nor in any way inflamed. On her return to the city in March, 1903, the motion of the face had become nearly normal, but her mother stated that the right eye was "smaller" at the time than the left, although they had been of the same size before. Dr. Talley saw her in October, 1903, and again treated her for irregular menstruation.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Examination.—Examination by Dr. William G. Spiller showed a slight stiffness of the right side of the mouth; the eye could be readily closed; there were no areas of anesthesia of the face or conjunctiva; the skin was entirely normal in appearance, but there was a distinct loss of subcutaneous fat which made the face flatter on the right side, and a sinking backward of the eyeball, as the accompanying photograph shows (Fig. 2). The electrical reactions, tested by Dr. C. S. Potts, were normal and no weakness of the muscles of mastication could be detected.

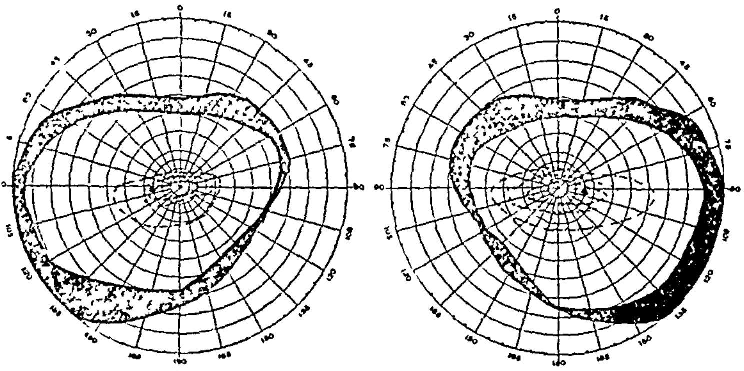

Fig. 1.—Case 1. Fields taken Jan. 6, 1904. Concentric contraction for form and color. No scotomas.

Examination by Dr. William B. Stanton in the medical dispensary showed normal lungs, slight extension upward of the heart dullness, on the left of the sternum, and a soft systolic murmur on lying down, heard best at about the third interspace, just to the left of the sternum, which disappeared on standing, and was probably hemic. The pulse was rapid but regular. Blood examination showed red blood corpuscles 4,248,000, white blood corpuscles 13,500, and hemoglobin 58 per cent. The urine was slightly cloudy, 1,030, no albumin or sugar; numerous epithelial cells but no casts.

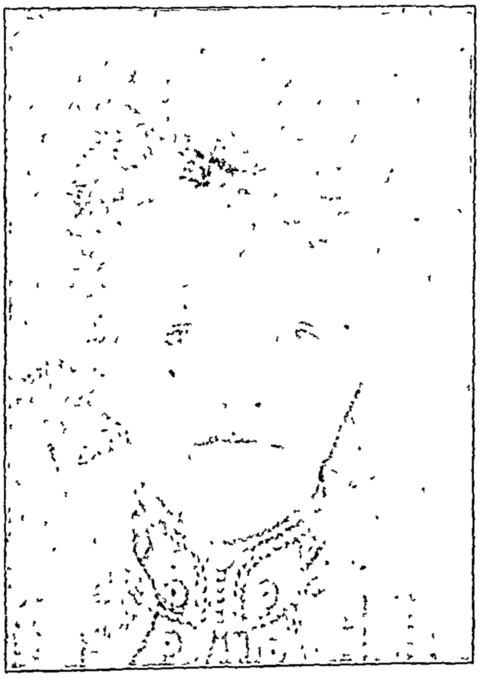

Fig. 2.—Case 1. Flattening of face and enophthalmus after facial paralysis associated with double optic neuritis.

Treatment.—Under atropin a vision of 8/22 was obtained in each eye, with + 0.25 s + 0.25 c ax. 90°. The patient was given strychnia sulphate, gr. 1/40, and Blaud's mass, gr, iii. three times daily. Subsequent examination showed a decided improvement in her general condition; her color became better, menses were regular and free from pain, and the blood test on April 6, 1904, showed red blood corpuscles 5,790,000 and hemoglobin 70 per cent. The vision at present is 6/20 in the right and 1/45 in the left, and the fields, taken May 20 (Fig. 3), show a slight reduction of the form field, and a marked reduction for red and green, but no color scotomas.

Summing up, we have an anemic girl with menstrual disturbance, who developed a peripheral facial paralysis of the right side, followed by flattening of the face and enophthalmus, which was associated with double optic neuritis and atrophy.

Several questions suggest themselves in considering the history of the case. In the first place, the etiology of the optic neuritis and the relation between it and the facial paralysis; secondly, the cause of the flattening of the face and the enophthalmus. Unfortunately, it is impossible to determine definitely the time of occurrence of the optic neuritis. The girl, however, had no trouble with vision or in the use of her eyes while at school, or in her occupation as a stenographer, and no deterioration in vision was noted until her absence from the city, during the attack of facial paralysis. This history is vague, but as no asthenopic symptoms were present until she commenced to use her eyes, on her return, we may assume, although without certain proof, that the neuritis and facial paralysis occurred about the same time. The association of the two conditions is quite uncommon. In 1894 Hoffmann[1] described two cases of facial paralysis, associated with low-grade optic neuritis, retrobulbar in type, with central scotomas for colors, and considered them as cases of multiple neuritis due to cold. He said that optic neuritis was very rarely associated with facial paralysis, and that Gowers had seen three cases of rheumatic optic neuritis in women, two of whom had suffered from neuritis of the facial nerve and other rheumatic affections previously. De Schweinitz[2] reported two cases in 1899, in which the optic neuritis, which was retrobulbar in type, with central scotomas, occurred two years after an attack of facial paralysis. In the first case, both eyes were affected, but not at the same time; in the second, there had been several attacks of sclerokeratitis, two attacks of right facial paralysis, and finally left-sided optic neuritis. Leszynsky[3] reported a case before the New York Neurological Society in 1900, in which, during an attack of facial paralysis, severe pain appeared in the supraorbital and temporal regions on the left side, which lasted about one week, when the

patient became blind in this eye; the ophthalmoscopic examination revealed a well-marked papillitis. He attributed the optic neuritis to periostitis in the optic canal, so that the condition was a multiple neuritis, probably due to rheumatism, although syphilis could not be positively excluded.

These 7 cases added to the present one, make a total of only 8 reported; the association is, therefore, quite rare. A number of cases of optic neuritis, however, has been reported in polyneuritis. According to Remak[4] in Nothnagel's System, it has been found by E. Remak, Goldscheider and Fuchs in spontaneous (infectious) polyneuritis, by Schanz in puerperal forms, with carcinoma (autointoxication) by Miura, in alcoholic polyneuritis by Lillienfeld, Giese and Pagenstecher, and Jolly. Other cases have been reported since Remak's article was written. For example, Wetz, in his inaugural dissertation, Giessen, 1903, gives a case of bilateral recurring retrobulbar neuritis, appearing at long intervals, associated with polyneuritis. But even the number of such cases is limited, and, with but few exceptions, the neuritis is retrobulbar in type, in both series.

Facial paralysis, according to Bernhardt,[5] is caused in about 72 per cent. of all cases by rheumatism or cold, and in our case the history of taking cold after exposure to a draught, points perhaps to this cause as the etiologic factor. Rheumatic optic neuritis was first carefully described by Parinaud[6] in 1884, and we owe most of our knowledge of these cases to his studies. In the majority of instances there is a family and personal history of rheumatism; the acute cases usually commence with deep orbital pains, and pain in movement of the eyeballs, which is increased by pressure on the eye. Very often it is accompanied by conjunctival and scleral congestion. The neuritis may be simple in type, or of the character of a choked disc; it is ordinarily monocular, and when it attacks both eyes it is successive. The most characteristic feature is the complete amelioration, which may follow a state of affairs apparently very grave, as the visual acuity may fall to zero, during the attacks, and yet return nearly to normal afterward. In several important respects, therefore, our case differs from the typical one of rheumatic neuritis. The absence of a rheumatic history, of spontaneous pain in the eyes, or on movement, the bilateral occurrence, and the permanent reduction in vision to 6/20 on one side and 1/45 on the other, with the formation of considerable connective tissue on the surface of the disc, would point to some other factor. Two conditions must be considered here—the chloranemia and the menstrual disturbances, in both of which optic neuritis may occur, and in which complete or partial recovery is possible, in contradistinction to the cases due to brain tumor, where the ultimate result is usually complete blindness, with marked atrophy of the papilla. The blood condition in our patient did not show a sufficient reduction in the hemoglobin to warrant a diagnosis of chlorosis, however, so that we must assume either that the menstrual disturbance was the direct cause, or else that the facial paralysis and optic neuritis were due to one and the same, still undetermined, perhaps bacterial, infection, a belief which is shared at present by many neurologists.

The other question as to the causation of the enophthalmus and flattening of the face opens up problems which are still under debate in neurologic circles. I have been unable to find any mention of such a condition following facial paralysis. Gowers,[7] in his well-known text-book, says that "muscular wasting follows the nerve degeneration in the face, as elsewhere, and in those who have but little subcutaneous fat, the loss of tissue may be perceptible." But "the nutrition of the subcutaneous tissues in unaffected, and true facial hemiatrophy never results from disease of the facial nerve." Nothing is said, however, of the occurrence of enophthalmus. Through the kindness of Dr. Wm. G. Spiller of Philadelphia I was able to examine a case of his, presenting the same condition, and I am permitted to refer to it here:

> The patient, Mrs. Rosa K., aged 52, suffered from peripheral right-sided facial paralysis after exposure to cold, in July, 1902. At the time of the attack she had severe pain on this side of the face. On examination in February, 1904, nineteen months afterward, the paralysis had disappeared except for slight stiffness of the face, but there was a decided flattening of this side, and distinct enophthalmus. The eyes, however, showed no ophthalmoscopic changes, and vision was normal in each eye, with the proper correction of a low refractive error.

The two cases have a history in common of paralysis following exposure to cold or draught, and of severe pain in the face and jaw lasting for several days. Neither presents a picture of typical facial hemiatrophy, for atrophy of the skin, with discoloration and thinning, constitutes the chief sign in this disease, and is absent in both. Simple wasting of the muscular tissue, as described by Gowers, would not account for the enophthalmus, and we are forced to look for some other cause. Sensory disturbances in facial paralysis, both subjective and objective, have long been known. Pains in the head and corresponding side of the face very commonly precede or accompany the attack, and some authors (Testaz[8]) ascribe a prognostic value to them. Disturbance of sensation is less rarely mentioned. Gowers has observed an anesthetic area in front of and behind the auricle, and, in more recent times von Frankl-Hochwart[9] and his pupil, Hatschek, have found decrease in general sensitiveness, pain and temperature perception in moderate degree in about 50 per cent. of their cases. More rarely vasomotor secretory changes are observed. There exists, further, in literature, according to Bernhardt,[5] a number of observations in which, simultaneously with more or less severe facial paralysis, there appeared an eruption of herpes zoster facialis or occipito-collaris, or both together. Von Frankl-Hochwart[9] believes that the seventh nerve carries a number of sensory fibers at its exit from the mastoid foramen, in addition to those which have passed into the chorda tympani, during its passage through the fallopian canal. This view has been strongly contested by many, but has received additional proof from experiments of Van Gehuchten,[10] who has shown that the nerve contains a certain number of sensory fibers which arise in the geniculate ganglion, and he believes that the nerve of Wrisberg is its sensory root. This question is still a matter of dispute, which we can leave to the neurologists to settle.

In our cases the assumption of involvement of possible sensory fibers in the seventh nerve will not be sufficient, as it would not account for the enophthalmus. This must be due to some nutritional disturbance of the orbital tissues, and as these are dependent on the supply from the fifth nerve, we must assume, I think, a neuritis of this nerve on the affected side. This, moreover, would explain the severe pain experienced by both patients, and the disturbance of sensation in the first. In the presence of polyneuritis involving the fifth and seventh nerves in both, I believe it would be justifiable to consider the optic neuritis in the first as due also to the same cause, infectious in character, rather than to invoke the additional factor of the menstrual disturbance or of the alteration in the blood.

CONCLUSIONS.

1. Optic neuritis is occasionally associated with facial paralysis, either alone or as part of a multiple neuritis; the etiologic factor may be rheumatism, but at times appears to be an infection, the nature of which is as yet undetermined. The optic neuritis is usually of the retrobulbar type, but a decided papillitis may be present, and be followed by more or less marked atrophy. In cases of multiple neuritis, of the cranial nerves, the eyegrounds should be examined for possible optic nerve complication.

2. In facial paralysis, flattening of the face and enophthalmus may appear, and are to be considered as due to a neuritis of the fifth nerve, and not to involvement of possible sensory fibers in the facial nerve.

DISCUSSION.

Dr. John E. Weeks, New York City, said that an interesting feature is the enophthalmus and the approach to facial hemiatrophy. He has recently observed a case in which this was a pronounced feature. There was no affection of the optic nerve, only of the facial nerve. It was a case in which the lesion was primarily an affection of the fifth nerve and, in this case, not only was there a disappearance of the fatty tissue of the face on the right side, but the bony structure was also reduced and the enophthalmus was marked. There was also atrophy of the iris which has not previously been noticed in cases of this kind. The pupil was widely dilated and immobile.

Dr. Edward Shumway said that, of course, true hemiatrophy is very different, because in such cases the essential condition is an atrophy of the skin itself, which is later followed by atrophy of the subcutaneous tissue and of the bony skeleton. Here the skin is unaffected.

A BACTERIOLOGIC STUDY OF THE BLANK CARTRIDGE.*

DAVID H. DOLLEY, A.M., M.D.
Resident Pathologist, The Lakeside Hospital.
CLEVELAND, OHIO.

It appears from statistics in The Journal of the American Medical Association, August 29, 1903, that of 392 cases of tetanus incident to accidents on the previous July 4, 363 followed wounds from the blank cartridge and the toy pistol. In other words, 92 per cent. of the tetanus cases were apparently attributable to wounds from blank cartridges.

Dr. A. I. Ludlow, assistant resident surgeon at the Lakeside Hospital, succeeded in isolating *B. tetani* from the blank cartridge wounds in one out of five fatal cases of tetanus, but cultivated the *B. aerogenes capsulatus* in four. In none of these cases was there emphysema nor emphysematous gangrene of the wounds, which were routinely treated by free incision and packing with iodoform gauze. In one of these which came to autopsy I failed to isolate *B. tetani* from the wound of the hand, but obtained *B. aerogenes capsulatus* from the local lesion and heart's blood. There was no gaseous emphysema of any organ.

These findings led me to investigate several makes of blank cartridges, and the results of these investigations form the basis of the present paper. The infectious agents concerned in these wounds (apart from the contents of the cartridge), may come from the skin and parts of clothing introduced. These latter sources of infection were not considered.

SOURCE OF MATERIAL.

The cartridges used were manufactured by the Peters Cartridge Co., the Winchester Arms Co., and the Union Metallic Cartridge Co., and were bought in the open market at various times and places.

CULTURAL EXPERIMENTS.

(*A*) *Wads.*—In both the cultural and animal experiments the wads were extracted with a sterile instrument, every care being taken to exclude accidental contamination.

The wads were placed in a 1 per cent. glucose bouillon, and incubated under anaërobic conditions (usually in Novy jars) at body temperature, for from 3 to 5 days, when coverslip preparations were studied. Not infrequently slender bacilli with end spores suggestive of *B. tetani* were seen. Nine cultures containing these tetanus-like bacilli were inoculated in fresh hematoma in the thigh of guinea-pigs. All of these animals survived but one, which died at the end of a month without symptoms of tetanus. These tetanus-like bacilli decolorized by Gram and were proved by cultural methods to be identical with a pseudo-tetanus bacillus discovered by Bain in blank cartridges. Many cultures contained a stout bacillus with square ends, apparently encapsulated, and subcultures made on glucose agar showed abundant gas formation. Nine rabbits injected with these gas-forming cultures, and killed ten minutes afterward, showed after from 8 to 20 hours' incubation marked gaseous emphysema, and *B. aerogenes capsulatus* was isolated from them all in pure culture. All efforts to demonstrate the presence of *B. tetani* failed. In a total of 250 wads examined by culture, the *B. aerogenes capsulatus* was demonstrated in sixty-six, or 26.4 per cent., and from sixty-one it was isolated in pure culture. Two of these were worked through all media, but in general the cultural characteristics on glucose agar, milk, and blood serum, together with the morphology, the capsule formation, the positive Gram stain, and the failure to grow aërobically, were deemed sufficient for identification. It is interesting to note that spore formation occurred in old milk and agar cultures, as well as on blood-serum. Some difficulty was experienced in separating *B. aerogenes capsulatus* from the other anaërobic organisms present in wads until Kitasato's method of heating for one hour at 80 degrees C. was adopted. It invariably survived this. That the explosion of cartridges neither kills nor inhibits the growth of *B. aerogenes capsulatus* was demonstrated by shooting the wads into jars containing melted glucose agar, which on incubation gave abundant growth of this organism in four out of five experiments.

The following table gives the proportion in which *B. aerogenes capsulatus* was found in wads of the different makes:

	Wads examined.	B. A. C.	Per cent.
Peters .32 caliber	54	32	[illegible]
Peters .22 caliber	50	21	[illegible]
U. M. C. .32 caliber	49	7	[illegible]
U. M. C. .22 caliber	50	0	[illegible]
Winchester .22 caliber	47	6	12.7
	250		

---

* Read before the Association of American Pathologists and Bacteriologists, New York City, 1904.

(*B*) *Powder.*—Cultures from the powder of 101 cartridges were usually sterile. Neither *B. tetani* nor *B. aerogenes capsulatus* was isolated.

INOCULATION OF ANIMALS.

At the suggestion of Prof. William H. Welch, the rat was used as being probably the animal most susceptible to tetanus.

To give *B. tetani*, if present, the most favorable environment possible, use was made of two procedures, the second one of which has not been employed in similar investigations. The first is inoculation of fresh hematoma, which increases greatly the chances of growth of *B. tetani*. As to the second one, Vaillard and Rouget established that "tetanus spores when free from toxin are innocuous when not accompanied by another bacterium, unless protected from phagocytes." Twelve white rats were inoculated under strict aseptic precautions with wads from the Peters Co. 32 caliber cartridges. In addition, a loop of a pure aërobic culture was added, in six an attenuated *Staphylococcus pyogenes aureus* and in the remaining six *B. coli communis*. The skin was then closed by a stitch and covered with celloidin.

Nine of these rats died in convulsions, the tenth quietly, while the other two survived. The incubation period varied from sixty to seventy hours. The character of the convulsions differed from that usually described for animals. The first symptom was a marked spastic condition of the inoculated leg, which was held in extreme flexion, explainable by the laceration of the extensor muscles. Gradually this spastic state extended to the whole body, so that the animal would retain its distorted shape in any position. In all, there was emprosthotonos, in two associated with pleurothotonos. The forelegs were held closely against the abdomen and the non-inoculated leg in extension. At short, irregular intervals there were definite convulsions, the most typical of which started with several rapid nods of the head, followed in order by clonic spasms of forelegs and hindlegs, passing in a few seconds into a tonic spasm of the whole body. In several, clonic spasms alone appeared. The convulsions lasted from one and a half to three hours, the animals all dying at the end of a spasm. At autopsy no lesions of internal organs were found. Smears from the meninges were negative for leucocytes and bacteria. Bearing in mind previous failures to cultivate *B. tetani* from wounds, it was thought wiser to subinoculate from these animals. Accordingly, the wads, with some necrotic tissue, were removed from six of the rats and inoculated into three guinea-pigs and three rabbits. The guinea-pigs died during the night, but the rabbits developed tetanus in about thirty hours. The character of the convulsions corresponded to the description in text-books.

In smears from the rats and guinea-pigs, a few spore-bearing bacilli morphologically resembling *B. tetani* appeared. These were somewhat more numerous from the rabbits. From one rat, only one such bacillus was seen after an hour's search. In all smears bacilli morphologically identical with *B. aerogenes capsulatus* were recognizable, together with numerous other organisms. Cultures were made from the wounds and wads on glucose bouillon and glucose agar, as well as blood serum. There was marked gas production, but repeated search failed to disclose *B. tetani*. Numerous subcultures, made both with and without Kitasato's method, were likewise negative. *B. aerogenes capsulatus* grew so rapidly and vigorously that it apparently crowded out *B. tetani*. Many anaërobic plates were also unsuccessful as regards *B. tetani*. In explanation of these failures, it may be said that the tetanus-like bacilli were extremely scanty, while *B. aerogenes capsulatus* was relatively abundant; and, further, that several other bacilli were present in the Peters wad, which resisted heating as well, one of these forming colonies much resembling those of *B. tetani*.

However, of five rabbits inoculated with five or six loops of the original cultures, three died in convulsions. Smears and cultures from their wounds were also entirely negative for *B. tetani*, though made as soon as symptoms of tetanus appeared.

The experiment was next tried of adding several crystals of urea to the material inoculated for its antichemotactic effect. In this rabbit the exudate was poor in leucocytes, and tetanus-like bacilli more numerous than in previous experiments, but *B. aerogenes capsulatus* had also increased proportionately and several series of plates were again negative for *B. tetani*.

A second series of inoculations with the Peters wads was next made. Three rats and three guinea-pigs were each inoculated with two wads, together with *Staphylococcus pyogenes mucus*, and several small crystals of urea. One rat and two pigs developed tetanus. As in the previous experiment, tetanus-like bacilli appeared in greater numbers than in the first series, but have not yet been isolated.

Inoculation experiments were also tried with the other brands of cartridges. In the case of the Union Metallic cartridges, the wads from the seven original bouillon cultures which yielded *B. aerogenes capsulatus* were used. One rat died without tetanic symptoms, the others survived. Likewise, thirteen wads of the Winchester cartridges, distributed among three rats and three guinea-pigs, produced no symptoms, and the animals survived the local suppuration produced by the staphylococcus.

Previous work has been done on this subject by Le Garde, Taylor, Wells, and the Boston Health Department, a total of 759 cartridges having been examined, both by cultures and animal inoculations, all with negative results for *B. tetani*. The only report of the finding of *B. tetani* in cartridges is made by R. N. Connolly, bacteriologist to the board of health of Newark, N. J. He bases his diagnosis, apparently, on the morphology and odor of cultures, and no inoculation of animals is reported. With regard to *B. aerogenes capsulatus*, Wells alone describes an obligate anaërobe which corresponds closely to this organism, but says it seemed to have motility, and it is not identified.

My thanks are due to Dr. W. T. Howard, Jr., and to Dr. Roger G. Perkins, for their valuable suggestions.

CONCLUSIONS.

1. *B. aerogenes capsulatus* (Welch) was present in a large proportion of the wads of the three makes of cartridges examined.

2. The wads of the Peters Company, inoculated in rats, guinea-pigs and rabbits, produced characteristic symptoms of tetanus.

3. The powder of the three varieties of cartridges examined was negative for *B. tetani* and *B. aerogenes capsulatus*.

4. My efforts at isolation of *B. tetani* from the wads have so far been unsuccessful.

5. There is abundant evidence, from clinical observations and animal experiments, that the wads of certain blank cartridges contain *B. tetani*. Dr. Welch told me that he considered it diagnostic to see an animal in convulsions.

THE PRESENT STATUS OF SURGICAL INTERVENTION IN RETRODEVIATIONS OF THE UTERUS.*

LUCY WAITE, B.A., M.D.
Head Surgeon Mary Thompson Hospital.
CHICAGO.

The business world has learned the value of frequent inventories of the stock on hand with a view to discarding the old-fashioned and shop-worn articles to make room for the new and up-to-date goods. It would be well if we of the professional world would follow their example, and take more frequent and accurate inventories of our work and be equally ready and anxious to discard methods which have proved useless and harmful.

The time has certainly come for the gynecologic surgeon to take a retrospective view of his work and ask himself honestly and seriously what operations have proven successful and beneficial to women as a whole, and what methods need revising or relegating entirely to the museum of surgical antiquities. No region of the anatomy offers so alluring a field for experimental surgery as the female pelvis, the practical immunity of the pelvic peritoneum from fatal peritonitis making it possible to do a great variety of operations in this region with a low mortality.

The ease with which the round ligaments can be reached by three different routes has given rise to so great a variety of methods of shortening this little cord that even an enumeration of them would be tiresome.

The different operative procedures which rescue the uterus from its safe retreat in the pelvis and suspend or fix it in an unnatural and dangerous position in the abdomen are also numerous. These various methods have naturally led to much operating in this direction, as each operator is bound to prove the advantage of his particular method, which can only be done by a dazzling array of statistics.

With the decline of oöphorectomy as a routine operation in pelvic disturbances it was but natural that some other procedure should take its place, and this time the surgical craze lighted on the uterus, and demanded that it be "hung up" by some one of at least fifty different methods. Several years of active operating in this field have now passed, and the testimony is beginning to come in. The examination and analysis of these reports is the object of this paper.

The following pertinent questions suggest themselves: 1. Are these operations necessary? 2. Are they safe surgical procedures? 3. Have they proven successful in a sufficiently large percentage of cases to warrant their continuance?

The answer to the first question depends largely on a second. What is the normal position of the uterus? Schultze[1] threw the first real light on this subject when he announced that a normal uterus must be mobile. Theilhaber,[2] Winters,[3] Winternitz[4] and many others have followed up his work and established the fact that uncomplicated retrodeviations of the uterus produce no symptoms, and, therefore, need no treatment, surgical or otherwise. Theilhaber distinctly says that by far the greater number of cases of retrodeviations produce no symptoms, and that gynecologists have mistaken the symptoms produced by the complications for the deviation in position. He lodges a severe indictment against the modern gynecologists, saying that many do not understand the new teaching of the clinical significance of retroflexion, and, moreover, many do not wish to know; *"viele nicht kennen und manche auch nicht kennen wollen."* He states that Schultze, Winckel, Landau, Freudenberg, Winters, Krönig and Fenwanger have made similar experiments, and that all have come to the same conclusion as himself, namely, that the majority of retroflexions cause no symptoms.

Winternitz says that retrodeviations are not the cause of the symptoms, and we have, therefore, to consider only the complications, and backs up this statement with the following statistics: In 710 apparently healthy women, 154 had retroflexed uteri; of these 154, 90 (60 per cent.) complained absolutely of no gynecologic symptoms. A closer examination of symptoms in the remaining 40 per cent. revealed the fact that in nearly all cases the symptoms were due to co-existing complications. He says that retrodeviation does not create congestions, and concludes: "To operate on a healthy woman because she has retroflexion is absolutely uncalled for."

In 396 cases, 39 per cent., out of 1,000, taken from the records of my clinic at the Mary Thompson Hospital, the uterus was found in retroposition, 62, 15 per cent. of these cases presented no gynecologic symptoms and were referred to the medical clinic. Without exception, *the remaining 334 cases presenting symptoms* were recorded as complicated with definite pelvic or abdominal pathologic conditions. These were classified as follows: Myomata, 24, 8 per cent.; ovarian tumor, 17, 6 per cent.; acute pyosalpinx, 8, 3 per cent.; chronic disease of ovaries and oviducts, 116, 35 per cent. In a large percentage of these cases pelvic exudates and extensive adhesions were found. Myometritis, 104, 30 per cent., one-third of this number being complicated with pathologic laceration of the cervix and consequent cellulitis; 8, 3 per cent., were pregnant at time of examination, and there were 6 cases, 2 per cent., of carcinoma uteri. In the remaining 55, 17 per cent., there were other complications, as appendicitis, hernia, nephroptosia, hemorrhoids and recent puerperal cases. There were among the entire number twenty-three extensive lacerations of the perineum, but as these were in every instance in complication with one or more of the conditions mentioned, I have not made separate account of them. These records were made without any reference to the subject under discussion, and many cases presenting no gynecologic symptoms were referred to other clinics without a pelvic examination. Therefore, the cases of retrodeviation presenting no pelvic symptoms, 15 per cent. may be said to have been discovered by accident. I am indebted to my associate on the staff of the Mary Thompson Hospital, Dr. Alice Conklin, for assistance in compiling these statistics.

Olshausen says that uterine catarrh does not come as a result of flexion. He says that it is only a coincident complication. Emil Reis,[5] in a discussion of the subject before the gynecologic society of our city, says that he does not consider retroversion in itself an indication for operation, and that in cases of retroversion complaining of pain he looks for the cause elsewhere.

If we accept Schultze's definition of the normal position of the uterus, that of perfect mobility, it would effectually do away with a large number of the operations under consideration, as it certainly could not be claimed that a uterus is in a more normal position fixed in the abdomen than if left a fixed organ in the pelvis, especially as the uterus is essentially a pelvic organ and leaves this region only to perform a physiologic function, to which it again retires unless prevented by some pathologic condition or by the ruthless hand of the surgeon.

The fixation of any viscus compromises its circulatory apparatus, both blood and lymph, interferes with its peristalsis, traumatizes its nerve supply, and with how much more force would this apply to a viscus removed entirely from the anatomic region assigned to it by Nature and forcibly detained permanently in a region remote from its anatomic and physiologic home. The conclusions of Thielhaber and others that uncomplicated retrodeviations are not subjects for surgical intervention rules out, without further discussion, Alexander's and all similar operations, as these can only be performed in uncomplicated cases, and, therefore, in those cases only needing no surgical interference whatever.

We may conclude, therefore: 1. That the normal position of the uterus is one of perfect mobility, and that a non-metritic, freely movable uterus may lie in any position in the pelvis without producing symptoms.

2. That when retrodeviation of the uterus is found in any given case of pelvic disturbance, further investigation will reveal complications which have produced symptoms.

3. It is, therefore, the complications which should be subjected to treatment and not the retrodeviation.

Our first question is, therefore, answered. Surgical procedures for the correction of retrodeviations of the uterus are unnecessary.

In regard to the second question: Are they safe surgical procedures? The testimony against these operations I have found so extensive that it will be impossible to give more than a brief summary. As surgical procedures they are all open to the same criticism; the gravity of the operation is out of all proportion to the results obtained. No surgeon can deny that in opening the abdomen there is always a possibility of infecting the peritoneal cavity no matter how rigid the asepsis or how skillful the operator, leaving behind if not fatal sepsis, pelvic exudates which can not fail to leave the patient worse off than when she came into the hands of the surgeon. The Alexander operation, which is, no doubt, of all this class of operations most extensively performed, practically weakens the abdominal wall at its already weakest points and leaves the patient in constant danger of hernia.

Milander[6] collected 54 cases of pregnancy and labor after ventrofixation; 11 of these cases, or 20 per cent., required severe operative delivery. Of Noble's[7] 76 collected cases, 30 per cent. experienced unusually severe labors. W. A. N. Dorland[8] collected 179 cases, in which 111, or nearly two-thirds of the whole number, experienced some uncommon abnormality in gestation or labor, or in both. In 38 per cent. of these cases disturbances occurred as complications of labor. Four cesarean sections and two Porro operations, which ended fatally, were performed on these cases, and in the remaining, other severe and uncommon operative aid was required. Bidone[9] publishes reports of four cases, out of six pregnancies following ventrofixation, of severe complications as the result of the fixation, and goes so far as to advise an abdominal section for the removal of the fixation two months before term in every case. Gradenwitz[10] cites six cases of complications. In two he re-operated some months after the first operation to relieve fixation. In two he operated for enormous hernias. The other two had very difficult labors, requiring instrumental deliveries.

Guerard of Dusseldorf says that fixation of the uterus is an unnatural procedure, and cites several cases where the fixation was excised before the patient recovered from the unpleasant nervous symptoms. Kreutzmann[11] reports that he made a careful study of the results of these operations during two years, and has come to the conclusion that ventrofixation is unphysiologic, unnatural and dangerous. Montgomery[12] has opened the abdomen during pregnancy to cut the band produced by a fixation before the uterus could develop normally. Dr. Edward Ricketts[13] of Cincinnati says: "After ventral suspension the woman takes her life into her own hands, and if she ever becomes pregnant she ought to agree to surgical intervention."

In a recent paper, Frank W. Lynch[14] of Baltimore collected a large number of cases of serious distocia following ventrofixation and suspension, among them 21 cases of cesarean section and ten ruptures of the uterus. A. Palmer Dudley[15] of New York says: Ventrofixation is a pernicious thing, and should never be done, from the obstetrical standpoint. Byron Robinson[16] reports a case seen in consultation with W. E. Holland, of labor at term following ventrofixation performed three years previously. The patient died of shock three hours following the delivery, and postmortem revealed invagination of uterus due to atrophy of the fundus caused by tension of the fixation bands on the fundus.

Reports of cases of ileus following these operations are just beginning to appear, and it is safe to say that there are others which have not found their way into print. Olshausen,[17] Rheul,[18] Jacobs,[19] and A. L Smith[20] each report one case. Rufus B. Hall[21] said he had to deal with three cases, and thinks the operation of ventrosuspension has had its day. Montgomery cites a case where a large portion of the intestine slipped below the band of adhesion immediately following the operation, causing strangulation and death. Similar cases, he says, have been reported by Lindfors, Jacobi, Olshausen and others. Fihling's[22] statistics show a mortality of 5 per cent. after all these operations, and that ventral hernia has followed them more frequently than all other operative procedures.

The operation which ranks next to ventrosuspension and fixation in point of dangerous results is undoubtedly vaginal fixation. The fact that both Mackenrodt[23] and Dührssen[24] have abandoned their methods of vaginal fixation on account of disastrous distocia following, ought to be sufficient to condemn this class of operative procedures; however, there are not lacking statistics. Edebohls[25] says that there were 25 per cent. of abortions in Dührssen's cases and 27 per cent. in his own, and that vesical pain and disturbances of micturition follow in a large per cent. of cases. Strassman[26] reports a case of transverse position, prolapse of funis, difficult version, postpartum hemorrhage; rupture at site of cicatrix and death from intraperitoneal hemorrhage; also one case of impossisible delivery *per vaginam,* necessitating a Porro operation. Graefe[27] reports a case of transverse presentation; the cervix was above the pelvic brim and directed upward; cesarean section was necessary. Wertheim[28] reports a difficult and dangerous version made necessary by the same condition. Ruehl[29] reports 235 vaginal fixations performed by himself, with twelve subsequent pregnancies. In three version was necessary; in two bloody incision of cicatrix; in one craniotomy in addition, the second child also being lost. Leo von Lingen[30] goes very thoroughly over the subject of vaginal fixation, and says the operation does not evidently appeal to Russian surgeons, as he has failed to find a single case reported by them. He cites the cases I have already given, and, in addition, cases of disaster reported by Veldi, Donhoff, Urban, Kallmorgan, Dielrich, Fuchs, Pape and Rieck. Among these cases were ten cesarean sections, six resulting fatally, and numerous abortions.

The various methods of shortening the round ligaments can not be classed as dangerous operations. The worst that can be said of them is that they are unnecessary, and have proven failures in a large percentage of cases. They will, therefore, be considered under my third and last question: Have these various operative procedures been successful in a sufficiently large percentage of cases to warrant their continuance?

It would seem hardly necessary to discuss the operations of ventrofixation and suspension from this point of view after the overwhelming testimony condemning them from the obstetrical standpoint. However, statistics are not wanting to prove that not only disasters follow in the train of these procedures, but a small percentage of anatomic failures. The greatest objection indeed, which can be raised against them, is that in a large percentage of cases they are a success orthopedically, as the Germans express it.

The percentage of disasters would be less if the percentage of failures in technic was greater. I have, however, performed five vaginal hysterectomies in cases where a ventrosuspension had been performed, and in only one case was the operation complicated by the previous operation. In one case of double pyosalpinx with dense pelvic adhesions, the fundus of the uterus was so firmly adhered to the abdominal wall that I was obliged to free the uterus through the abdomen before finishing the operation *per vaginam.* In the remaining four, the suspensory bands had elongated and thinned, and were only discovered when the fundus was reached in the course of the operation. In one case the band measured five inches. Edebohls[31] found the cervix protruding from the vulva, in one case where he removed the uterus, while the suspensory ligament was still firmly attached to the fundus.

Knorre[32] gives the following interesting statistics: In 4 only, of 24 cases of vaginal fixation, were the orthopedic and functional results good. In 5 the orthopedic results were good, the functional bad. In 4 cases the uterus was retroverted as before the operation, but the patients reported all the symptoms improved. In 11 of the 24 the operation had failed utterly to correct the retrodeviation, and symptomatically the patients remained the same. An interesting report comes from C. W. Oviatt[33] of Oshkosh. He says he has done Noble's operation for retroversion 23 times. In 20 of these there were complications, such as recurring appendicitis and pelvic tumors and diseased appendages, all of which complications were attended to at the time of fixing the uterus. He states that in three uncomplicated cases of retroversion there has been no improvement in the dysmenorrhea, and little or none in the general conditions.

A most significant report comes from the St. Petersburg clinics. T. Dolbert[34] gives the results in 79 cases where ventrofixation was performed, and concludes with the statement that the fine objective results were not paralleled by the subjective, as these returned in more than a third of all the cases, indicating that the neurosis apparently attributable to the displacements is in reality more or less independent of it. Richard C. Wadsworth[35] reports 22 cases of ventral fixation performed at the Massachusetts General Hospital. Only 23 per cent. of these received symptomatic relief. Theilhaber[36] has examined a large number of cases of hysteropexy, and found that the operation does not diminish leucorrhea or hemorrhage.

The many later and newer methods of shortening the round ligament, many of them necessitating the opening of the abdominal cavity, are the severest criticism which can be made on the Alexander operation. Certainly, with the exception of the danger of subsequent hernia. the Alexander offers the least objections of all the numerous methods, and unless it has been found lamentably wanting, there would be no excuse for the innumerable and more objectionable methods. Kleinwächter[37] says that the Alexander operation is illusive, the retroversion recurs, and that the per cent. of hernia following is too large to warrant the operation. I have examined six cases where the uterus was found in retroposition. In one case there was a double hernia. This operation was performed by one of the most skillful operators of our city, and the result can not be blamed to faulty technic.

A great point is made by the advocates of the round ligament operations that no disasters follow in subsequent pregnancies. There is no reason why pregnancy and labor should not proceed normally in these cases, especially in those where the operation has failed to change the conditions in the pelvis. Andersch[38] reports 37 cases of vaginal shortening of the round ligament with anterior and posterior colporrhaphy. Of these, 29 were examined subsequently after two or three years. He found good results in 15, and recurrences in 14. Halban[39] reports a large number of round ligament shortening by different methods, and says that there were more anatomic cures than cases where subjective symptoms were relieved, as the latter were not due to the retroposition.

From the statistics cited and the testimony presented by the numerous witnesses quoted in my paper, as well as from the results of my own clinical observations, I feel warranted in answering the questions asked in the negative. Surgical procedures in retrodeviations of the uterus are unnecessary. They are unsafe, and have not proven successful in a sufficiently large percentage of cases to warrant their continuance.

BLOODLESS PERINEAL PROSTATECTOMY UNDER LOCAL ANESTHESIA.

MARTIN B. TINKER, S.B., M.D.

Lecturer on Surgery, Cornell University Medical College; Surgeon to the Clifton Springs Sanitarium.

ITHACA, N. Y.

The problem of prostatic hypertrophy, even with the many resources recently introduced and developed, still offers in certain cases many difficulties in its solution. Patients are practically always of advanced age, weakened through pain and loss of sleep for months, and are very unfavorable subjects for any anesthetic or any form of treatment. Catheterization is often difficult and even when easy it is almost impossible to teach the average patient the details of aseptic catheter technic, and to impress him with the importance of its careful observance. Comparatively few patients survive catheter life for many years, and the development of more or less severe cystitis, with its dangers and discomforts, is the rule. Even if the patient gets on with the catheter with comparative comfort, it is not difficult to understand how irksome it must be to depend on the catheter constantly. The Bottini operation has not been without a high death rate, even in the hands of the most experienced and successful of its advocates; it is sometimes followed by incontinence of urine and not unfrequently fails to give relief. Even if its disadvantages were less, the idea of burning a channel through the tissues blindly, with all the possibilities of infiltration of urine, does not appeal to one as a very desirable surgical procedure.

Prostatectomy, when carefully performed, is generally recognized to be the ideal procedure; it gives perfect and permanent relief, and a condition nearer the normal than can be attained in any other way. The dangers of the operation are from the general anesthesia in old and weakened patients and the loss of blood. Before the operation was perfected, as it has been recently, the loss of blood was undoubtedly a factor greatly to be dreaded, but through the introduction of various forms of prostatic tractors it has been possible to greatly reduce the depth of the perineal wound and to make the control of hemorrhage much easier. Of these various forms of tractors devised by Syms, Murphy, Ferguson, Bryson and Young, it has seemed to me that Young's instrument has some advantages. But even with the almost perfect control of hemorrhage the administration of general anesthesia to these greatly weakened, old men is a dangerous matter, and for some months I have been considering the possibility of performing prostatectomy under local anesthesia and devising the means for this purpose. In the weakened and most run-down of my patients I have employed permanent suprapubic drainage of the bladder to save the life of men too much weakened to undergo the more serious operation. This operation can be done in a very few minutes under eucain, and, I believe, is the safest of all procedures. But for men not in absolutely desperate condition I believe that prostatectomy under local anesthesia is an operation which can be performed, as a rule, quite as safely as the Bottini operation and with only the slightest risk as compared with the operation under general anesthesia. Spinal anesthesia has been used by some surgeons in these cases, but even its most enthusiastic advocates are forced to admit that the death rate, reported from many sources, shows it to be unsafe in the hands of the average man. No series of a thousand cases or over without one or more deaths has been reported, while many careful men have lost larger numbers out of a hundred or less spinal anesthesias. General anesthetics, even when carelessly used by untrained men, have not given such a mortality, and this has led nearly all those who adopted spinal anesthesia a few years ago to abandon its routine use. On the other hand, I am not aware that a single death has ever been reported from among the many thousands of cases in which the infiltration of weak solutions of anesthetic drugs has been used. As a local anesthetic, I have been using recently a solution of beta eucain, 1 to 500, with an addition of adrenalin chlorid to make 1 to 120,000, or, in cases where large quantities of fluid are used for infiltration, even weaker solutions. The addition of adrenalin chlorid, by constricting the capillary vessels, arrests even the oozing and makes the operation an almost bloodless one. In these cases I believe that the saving of even this small amount of blood may make the difference between life and death for some of our patients. The eucain is estimated to be five times less poisonous than cocain, and in over one hundred major operations in which I have used it I have never seen symptoms of poisoning from the drug. The use of adrenalin has additional advantages besides saving blood; it prevents the absorption of the anesthetic drug and, by rendering the part bloodless, it also greatly prolongs and adds to the efficiency of the anesthesia; it prevents the congestion and pain after the operation, which is sometimes seen with the use of ordinary Schleich's solution and, from its action on the general circulation, Crile has shown it to be one of our best circulatory stimulants.

In the use of local anesthesia a most thorough knowledge of the anatomy of the parts is desirable. Through the kindness of Prof. Abram T. Kerr, I have had the privilege of examining a number of dissections of the region of the perineum and prostate in the Cornell University Medical College anatomic laboratory, and I wish to acknowledge the value of this privilege and the helpful suggestions from Dr. Kerr in working out the steps of the operation.

DISTRIBUTION OF NERVES.

An accurate knowledge of the location of the nerves supplying the skin and deeper structures of the perineum and a thorough anesthetization of these nerves at the start is the key to the whole situation, in performing a painless prostatectomy under local anesthesia. Examination of a dissection of the perineum shows numerous nerve branches ramifying in various directions, and at first sight the nerve supply of the perineum seems very complicated. Following these smaller branches back to their main trunks, we see that it is comparatively simple, for the entire nerve supply of this region comes from two main trunks, the pudic nerve, which is formed chiefly from the third cord of the sacral plexus, but also receives communicating branches from the second and fourth sacral nerves, and the long pudendal nerve, which is a branch of the smaller sciatic nerve. References to these nerves in different text-books and atlases of anatomy show differences of opinion as to exact position, but the latest and most accurate authorities are agreed, in the main, as to the location of the nerves of the perineum. In the dissecting room I have found considerable variation in these nerves. But whether the nerves supplying the different parts of the perineum come from two main trunks or from several branches it will be found practically always the case that these nerves take their origin from the main stem or stems, which lie very close to the base of the tuberosity of the ischium. The depth from the surface varies slightly, but it can be estimated quite accurately, within a limit of half an inch, I believe, and this is not too wide a range of error to interfere with thorough anesthetization of the main nerve trunks. The perineal branches of the pudic nerve are by far the most important of these perineal nerves. Superficial fibers run more or less nearly parallel to the transversus perinei muscle. Other small fibers run obliquely forward to the region of the front of the anus, while anterior fibers run to the region of the base of the scrotum and the bulb. The pudendal nerve supplies only the outer region of the perineum and the region far forward, near the base of the scrotum.

---

[38] Andersch: Arch. f. Gyn., Berlin, 1902, vol. lxv, p. 217.

[39] Halban: Mon. f. Geb. u. Gyn., January, 1900.

METHOD OF ANESTHETIZING MAIN TRUNKS OF PERINEAL NERVES.

After the usual antiseptic preparations, the first step of the local anesthesia operation is the infiltration of the main trunks from which these various nerve branches take their origin. Taking the tuberosity of the ischium as a landmark, the needle of the infiltrating syringe is inserted in the skin about one inch in front and internal to the tuberosity. It is not necessary to infiltrate a large area in this region and the weaker solution of eucain, 1 to 500, with adrenalin, 1 to 120,000, is used to infiltrate the skin and outer layers. Injecting small quantities of fluid before the needle as it is pushed forward, the point of the needle is carried downward and outward toward the front of the base of the tuberosity of the ischium. The superficial tissues are thus thoroughly infiltrated and the needle is pushed forward until it comes in contact with the bone. From 30 to 60 minims of a stronger solution, 0.5 per cent. eucain with adrenalin, are then injected at a depth of from one to two inches, varying with the thickness of fat and muscle in the region of the ischiorecta fossa in front of the tuberosity of the ischium. Experimental injection of a fluid containing coloring matter into muscles or fat and loose cellular tissues, such as is found in the ischiorectal fossa, will demonstrate very conclusively to anyone interested enough to try it how wide an area around the point of the needle is affected by the solution. Thirty minims of the 0.5 per cent. solution is soon so diffused through the tissues that it affects an area from 1½ inches to 2 inches in diameter and is almost certain to thoroughly anesthetize the main trunks of the perineal nerves. In order to make absolutely sure that the patient suffers no pain during the division of the tissues, the skin in the medium line of the perineum or in the direction of whatever line of incision may be considered desirable, is thoroughly infiltrated with the weak solution, 1 to 500 eucain with adrenalin 1 to 120,000. The influence of the adrenalin in preventing absorption of the anesthetic drug and the very weak solution used makes it possible to employ large quantities of solution without any poisonous symptoms. Adrenalin solution also effectually prevents oozing from small blood vessels, and, with a little care in controlling the larger blood vessels, the loss of blood can be reduced to the minimum. I doubt if in my first operation over a tablespoonful of blood was lost throughout the entire operation.

TECHNIC OF OPERATION.

After infiltrating the main nerve trunks and injecting a large quantity of the weak solution in the region of the proposed incision, a sound is introduced into the bladder and partially withdrawn so that the tip remains in the prostatic urethra. The time taken to thoroughly irrigate the urethra and insert the sound gives the eucain solution time to take effect. It is desirable not to begin the incision too soon after infiltration, for it should be remembered that it takes the solution from three to five minutes to thoroughly numb the parts. After the introduction of the sound, the operator should change his operating gloves. He is then ready to make the skin incision.[1]

I am sure that the testimony of my patient, a judge in a neighboring state, will be accepted as trustworthy. In speaking of the operation, he has repeatedly expressed wonder and satisfaction that throughout the steps of the operation, from the time that the needle was introduced, he felt absolutely no pain. The operation proceeded without any delay because of sensitiveness of the parts which were being divided. As the deeper tissues were exposed, the infiltration of the weak solution was carried deeper into the wound. In opening the prostatic urethra and inserting the tractor, slight discomfort was complained of, but this was only transient. The firm traction, which is possible with the use of Young's instrument, absolutely controls hemorrhage from the deeper vessels and they are brought so near to the surface they can be readily secured before they are divided. Exposure of the anterior part of the capsule and enucleation along the sides is carried out in an area that can be thoroughly infiltrated. The deeper enucleation, a matter of but a few minutes, has to be performed in a region which can not be reached satisfactorily with the infiltrating solution. This region of the neck of the bladder and the prostate itself, is supplied by the hypogastric plexus of the sympathetic nerves, and the discomfort of enucleation is not great. In many cases I believe it would be possible to complete the entire operation under local anesthesia. In the cases of extremely nervous or sensitive patients it will be found wise to use a little nitrous oxid gas or primary ether anesthesia. This part of the operation need not consume five minutes' time and is a matter of far less importance in these cases than the use of general anesthesia throughout the entire operation. which can not be performed in much less than one-half hour at the best.

ILLUSTRATIVE CASE.

The following is the history of a case in which the local anesthesia method was employed with great satisfaction to the patient and to me. When the patient's condition before the operation is considered, it does not seem too much to say that the use of local anesthesia was the means of saving his life.

---

[1] In the further steps of the operation I follow in almost all details the method described by Young in The Journal A. M. A., Oct. 26, 1903.

Patient.—The patient was an extremely emaciated man, who had been suffering from bladder trouble for over ten years.

History.—For the past three years the difficulty in urination has been very great. During a year previous to the operation, the patient had not been able to retain his urine longer than an hour at any time, and, for the most part, he has been up every hour during the night for months past. He had lost over thirty pounds in weight, and was so weak that he was scarcely able to be about. The pain and constant loss of sleep greatly interfered with his digestion. He had scarcely any appetite; his stomach at times was unable to retain even the most simple food. The prostatic enlargement considerably interfered with movements of the bowels.

Examination.—When first seen, his bladder was distended to the level of the umbilicus, and, on catheterization, 1,250 c.c. of urine was withdrawn. Both the soft and metallic catheter passed readily. The urine had a very foul odor; was pale in color; specific gravity, 1,005. Heavy ring of albumin: no sugar. On microscopic examination, it was found to be filled with pus, numerous triple phosphate crystals, a few red blood cells. No casts were seen. On rectal examination, the prostate was felt as a rounded mass, the size of a medium-sized orange; by pressure it almost closed the rectum and was tender on rectal examination.

Preparatory Treatment.—Three days before the operation, a permanent catheter was fastened in the bladder, but the patient found it so disagreeable that it was discontinued. He was impatient with the idea of palliative treatment by drainage, and arrangements were made for operation. During the time before the operation he was catheterized twice daily, and his bladder was irrigated with boric acid solution. Under this treatment, the blood disappeared from his urine and the amount of pus was greatly reduced. The patient slept somewhat better, although, of course, he was obliged to be up nearly every hour during the night. On the morning of the operation, the bladder was irrigated on the operating table and a small amount of solution was left in the bladder.

Operation.—April 14, 1904. Anesthetic, eucain, 1 to 500; adrenalin, 1 to 120,000. The patient was placed in the lithotomy position, and the parts were anesthetized as above described. An incision was made in the median line, exposing the membranous portion of the urethra. The field of operation was rendered practically bloodless by the use of the adrenalin solution. The few vessels from which there was bleeding were secured without difficulty, and a perfectly dry, clean dissection was possible. A sound was passed into the bladder and on this the urethra was opened. The urethra was secured on either side by stay sutures of heavy linen and was held open while Young's prostatic tractor was inserted into the bladder. This was accomplished without any difficulty. Moderate traction was possible after the instrument was in place without causing discomfort, but firm traction caused considerable pain. The dissection was then continued until the capsule of the prostate was opened. The capsule was dissected off by blunt dissection, well down to the side of both the right and left lobes. A little extra fluid was infiltrated along the sides of the capsule. Up to this time the patient did not complain of pain from the operation itself, but said he suffered more discomfort from his cramped position on the table. It was evident, however, that it would be impossible to make firm traction on the prostate so as to bring it well down to complete the enucleation without causing a good deal of pain, hence primary ether was administered by Dr. Sanders. Only a small amount of ether was used, and the patient took it quietly, without change of the lithotomy position. The wound was covered with wet bichlorid towels and all instruments were taken off before the ether was begun, but the patient did not struggle at all, and this was really an unnecessary precaution. Enucleation of the deeper part of the gland was without special difficulty, but Young's lobe forceps were found of service in grasping it and drawing it down into the wound. The right lobe was enucleated first, then the left lobe was attacked, and finally the middle lobe, which was not very greatly enlarged, was also enucleated. The duration of anesthesia for enucleation of the deeper parts of the gland did not exceed ten minutes, and in another operation, with the experience of this one, it would be perfectly possible to remove the gland in five minutes or less of general anesthesia. A glass and a rubber drainage tube were inserted, the glass tube entering the bladder and the rubber tube being carried into the large cavity left between the rectum and the neck of the bladder. The hemorrhage during enucleation was insignificant; it is doubtful if a tablespoonful of blood was lost. The cavity was packed with iodoform gauze strips, and the perineal opening was partially closed with catgut sutures. While on the carriage and after cleaning up the skin, an infusion needle was inserted beneath the pectoral muscle on the right side and 1,150 c.c. of warm normal saline solution were run in. The fluid was quite readily absorbed. On the operating table, the patient had one-thirtieth of strychnin, with a preliminary dose of morphin, gr. 1/6, and after being put to bed, a second hypodermic injection of one-fortieth of strychnin was administered. The pulse was very good, though it showed some shock, and hence a hypodermic of one-thirtieth of digitalin was given after the strychnin. The pulse soon improved, and was better than before beginning the operation. Urine drained freely from the perineal incision after the operation, but, in spite of this, the patient remained in a rather comatose condition well into the evening, and it was feared that uremia was developing. Infusions of salt solution were used freely and were rapidly absorbed. In all, five infusions were given, 1,000 c.c. being used at each time except the first infusion. The patient's condition steadily improved during the day of the fifteenth. Urine drained profusely from the perineal wound, rapidly saturating pads. The patient retained liquid nourishment from the start without difficulty: no nausea or vomiting at any time. The quantities of nourishment were very rapidly increased and solid food was soon added. In addition to three hearty meals a day, the patient took large quantities of liquid nourishment at intervals between his regular meals. The albumin of not less than two dozen eggs was given him daily. The extra nourishment was given him for over four weeks, and, whereas before the operation the patient had found great difficulty in digesting even simple food, he was soon able to take very hearty meals with great relish and without the slightest trouble from indigestion. The urine drained freely from the wound and with the complete relief from pain, the patient showed very rapid improvement.

Result.—Six weeks after operation he was in excellent general condition, still taking large quantities of nourishment, gaining rapidly in weight and strength, and passing urine through the urethra.*

At the time of writing, over four months after the operation, the patient is apparently in perfect general health; he walks five miles with ease, has gained over 30 pounds, looks and says he feels like a new man. With the exception of a pin-point opening, from which occasionally a few drops of urine escape, sometimes at intervals of several days, the large perineal wound is perfectly healed.

In this case I believe that the operation under local anesthesia made it possible to save a life. Operation had been considered inadvisable by surgeons of repute in a neighboring large city. The use of large quantities of salt solution subcutaneously to stimulate the action of the kidneys is a matter of great importance, which has been previously emphasized by others. In the further after-treatment, the use of tonics and of large quantities of nourishing food are the main points to be remembered.

---

*As this paper goes to press a second patient is recovering from local anesthesia prostatectomy. He also was in extremely bad general condition; unable to void any urine without a catheter, bladder distended above umbilicus when first seen, greatly reduced in flesh and strength. A number of visiting physicians are ready to testify as to the freedom from suffering of the patient under the local anesthesia. Patient doing well five days after operation.

In conclusion, I would say that for the surgeon who does not consider his own time and trouble a matter of greater importance than the life which the patient entrusts to his care, the local anesthesia operation offers a means of greatly reducing the dangers of prostatectomy in critical cases.

Special Article.

IMMUNITY.

CHAPTER III.

GENERAL CONSIDERATIONS.

Definition.

By immunity we understand that phenomenon in which an individual or a whole class of animals exhibits such resistance to an infection as to withstand it, while under the same conditions another individual or another class of animals may yield to it. Immune is from the Latin *immunis,* which meant exempt from a public service, exempt from tribute, or free. Although the word retained this civil meaning for centuries, and still retains it in certain connections, it also had in ancient times a limited application to the protection which an individual might possess against poisons. It is seen, for example, in descriptions of the Psylli, a tribe inhabiting Northern Africa, which possessed a *natural immunity to the bites of poisonous snakes. Although the fact of immunity was known in very ancient times,* the present significance of the term has developed largely from a better understanding of the nature of infectious diseases and of the resistance of the body against them.

Diseases Concerned in Immunity.

As the definition of immunity suggests, we do not think of immunity to such processes as Bright's disease, arteriosclerosis or the metabolic diseases, but only those which we have learned to recognize as infectious.

Immunity to an infectious disease has no necessary relationship to the degree of its contagiousness, although some of the most striking and certainly the most common examples of immunity follow some of the contagious diseases (as scarlet fever and smallpox). Tetanus, on the other hand, which is absolutely non-contagious, can equally give rise to a high degree of immunity.

Acquired Immunity.

No medical fact is more widely known among intelligent people than that an attack of certain of our infectious diseases brings about some kind of change in the patient's tissues which protects him, or renders him immune, against further attacks of the same disease. Inasmuch as he was previously susceptible, the new property is an acquired one, and he is now said to possess *an acquired immunity* against this disease.

Natural Immunity.

It is also well known that many diseases which attack man can not be inoculated into the lower animals, and biologists are familiar with many other examples of immunity which are confined to a species. The lower animals apparently can not be infected with scarlet fever or measles, nor man with chicken cholera. The negro is less susceptible to yellow fever than the white man. The resistance which these examples illustrate has occurred naturally, not through having the disease; it is a natural immunity.

Family Susceptibility and Immunity.

Natural immunity is for the most part an inherited condition; this certainly is the case when a whole class of animals is involved. Similarly, the susceptibility which is peculiar to a species must be hereditary. It is often said of some diseases that they run in families; e. g., carcinoma, gout, insanity. This appears to be just as true of some *infectious* diseases, the most noteworthy example of which is probably tuberculosis. *In contrast to this inherited susceptibility* is an inherited *immunity, which may also run in families.* It is not so easy to adduce examples of this. We are in the habit of thinking of the individual who can resist all infections as representing a standard. He, however, is above the average in resistance, and the average is our proper standard for estimating the resistance of a species or race of animals. It is undoubtedly true that some families possess an unusual resistance to tuberculosis. Furthermore, experimental work with animals has proved that, within limits, an immunity to certain infections (e. g., tetanus) acquired by a female may be transmitted to her offspring. *Even in a given family, however, there are often marked variations in susceptibility and resistance. One child may contract scarlet fever,* while his brother, living under exactly the same conditions, may escape it. There is, moreover, much reason to believe that the same individual varies greatly in his resistance at different times and under different conditions. Hence, the personal equation, as shown by individual immunity or individual susceptibility, is of no small consequence.

The facts mentioned were familiar long before anything was known regarding the principles on which they depend. Subsequent to the discovery of some of these principles (to be considered later), it became convenient and necessary to recognize other special types of immunity, although any type *which can be conceived must still find a place under either natural or acquired immunity.*

Antibacterial and Antitoxic Immunity.

It seems certain that such diseases as typhoid and cholera can occur only when the microbes themselves are present in characteristic localities. Although these diseases are accompanied by pronounced toxic symptoms, the poisonous substances seem to be integrally associated with the bacterial protoplasm and not secreted in a soluble or diffusible form. Observations point to the belief that their toxins are liberated only after the bacteria are killed and dissolved. Hence cholera, typhoid and many other diseases which resemble them in this respect, are in a peculiar sense bacterial diseases. *On* the other hand, the symptoms which are so *characteristic* of tetanus are produced not by contact of the bacteria with *the nervous* system, but through the poison secreted by the *tetanus bacilli* in the wound where they reside. This poison, or *toxin, goes* into solution and is carried from the wound to the nervous system. Therefore, although tetanus is a bacterial disease, it is at the same time and in a peculiar sense a toxic disease. Bacteria which conduct themselves like the organisms of typhoid *and* cholera are said to possess intracellular toxins. *Now experiments* show that the serum of an animal which has an immunity against typhoid or cholera infection is able to kill the respective bacterium, but apparently is not able to *neutralize* the *toxic* substance in the bacterium. Hence, immunity to such diseases is spoken of as antibacterial.

On the *other* hand, the serum of an animal which is immune to *diphtheria* or tetanus, diseases caused by the soluble, extracellular microbic toxins, will neutralize these toxins without having any necessarily injurious action on the bacteria themselves. That is to say, the immunity is antitoxic. Experience has *shown* that this distinction between antibacterial and *antitoxic* immunity is an important one, and the differentiation seems to be a very sharp one. As a good illustration of its *importance,* we may say that no one has ever obtained a successful *antitoxin* for typhoid by the immunization of animals, the *resultant* serum being antibacterial rather than antitoxic. It is *obvious* that natural immunity may be in one case antibacterial and in another antitoxic; and the same is true of acquired *immunity.*

Active Immunity.

Immunity which is acquired as a result of an infection depends on a specific reaction on the part of the tissue cells in response to the chemical injury produced by the bacteria or their toxins. In view of the active part played by the body in establishing this new resistance, the condition is referred to as an active immunity. In the preparation of our various antitoxic and antibacterial sera for commercial purposes, a condition of active immunity is deliberately produced in the animals (the horse, for example,) by the injection of the toxins or of the bacteria.

Passive Immunity.

Contrariwise, the resistance which is established in an individual through the injection of an immune serum (such as diphtheria antitoxin) is a passive immunity, since it depends on the introduction of ready-made immunizing substances rather than on their production through an active process on the part of the one injected. Active and passive immunity, then, are varieties of acquired immunity. Depending on the disease which caused the immunity, or on the character of the serum injected, they may be either antibacterial or antitoxic.

Relative and Absolute Immunity.

Any one of the types mentioned may be either relative or absolute; synonyms are partial and complete. If absolute, infection is impossible. If only relative, different conditions may be made to prevail which would render infection possible: for example, a large number of bacteria will often cause an infection where a smaller number fails to do so. There may also be a temporary decrease in one's resistance through overwork, hunger or exposure. Immunity is usually relative.

Classification of Types.

By proper combinations of the terms which have been enumerated. one may describe somewhat accurately the different forms of immunity. Thus, a child which has received a prophylactic injection of diphtheria antitoxin is in a state of acquired passive antitoxic immunity to diphtheria. If immunity to typhoid has developed as a result of the disease. the condition is that of an acquired active antibacterial immunity, etc. Accordingly, although the terms may be somewhat confusing. it is seen that they are in no sense contradictory.

In tabular form, the different types may be placed as follows:

IMMUNITY.	Natural. The inherited immunity of species and varieties of animals. Inherited family or individual immunity. Acquired. Active. Passive.	Antibacterial or Antitoxic.

In many of these conditions proper biologic experiments will demonstrate the presence of the antibacterial or antitoxic substance in the serum of the animal which possesses the immunity. The technic of such experiments will be illustrated later.

Drug Habituation.

There is another kind of acquired resistance which properly may be mentioned here. It is a well-known fact that one may gradually accustom himself to enormous doses of morphin, arsenic, alcohol and some other drugs. *A priori*, it would seem that this condition of resistance should be analogous to that which is present in antitoxic immunity. But, on the contrary, the serum of a morphin or alcohol habitué has no power of neutralizing the effects of morphin or alcohol. The conditions on which this resistance depends are not understood.

CHAPTER IV.

HISTORY AND DEVELOPMENT.

Early Times and Practices.

The conception of the nature of immunity which was current at one period or another of history had some relationship to the conception of the etiology of diseases at those times. It will be remembered that at one time diseases were supposed to be imposed by an angry deity, and to avert them various mysticisms were resorted to, such as the utterance of incantations and the wearing of talismans. On the other hand, a more logical attempt to explain the natural immunity of the Psylli against snake poison was made by Pliny, who suggested that it might be due to their habit of drinking water from wells in which poisonous snakes dwelt. This is not unlike our present conception of active immunization.

Von Behring quotes literature to show that among some primitive races of to-day, artificial immunization is carried on; a Mozambique tribe is said to inoculate against snake poison by rubbing into a small cutaneous incision a paste which contains venom. Probably non-fatal quantities are introduced in this way, resulting in the formation of venom antitoxin, a method comparable to that used in the production of diphtheria antitoxin.

A type of immunity which we call drug habituation early became known. We learn that Mithridates by taking gradually increasing doses of poisons established in himself resistance of this sort. It is stated also that he fed ducks with poisons and then proposed to use their blood as an antidote (serumtherapy). The importance of antidotes in the minds of the ancients may be appreciated from the fact that epidemic diseases, such as plague, cholera and smallpox, were at one time considered as due to unknown poisons, which might be comparable in nature to some known poisons, as aconite. Mercury for syphilis, quinin for malaria, and salicylic acid for rheumatism would certainly have fallen into the category of antidotes, and mercury may have been so considered.

A historic illustration of the treatment of disease on an etiologic basis is found in a theory which was prevalent in the seventeenth century, according to which diseases were either acid or basic in character, and hence should be treated, the one with an alkali, the other with an acid. Sylvius considered plague to be of acid nature and administered alkalies, while Etmüller took the opposite view.

Manifestly, rational treatment and prophylaxis of the infectious diseases could not be undertaken until their etiology was correctly understood. Yet here, as has so often happened in medicine, empiricism preceded rationalism. For example, protective inoculation did not become a principle until the time of Pasteur, yet it had been practiced against smallpox for centuries, and the method put on its present basis by Jenner long before there was a clear idea as to the *modus operandi* of the protection which resulted.

(*To be continued.*)

Football.—Prof. Burt G. Wilder, of Cornell University, who opposes intercollegiate football games and favors intracollegiate football, said. Some day the national sense of humor will vie with mortification over the record that our universities were once known most widely through the prowess and mishaps of a few score football champions. For the most part those men were intended by Nature and environment for simple and useful lives as students and citizens. They were endowed with the strength and activity that daily moderate exercise would maintain as the most perfect basis for mental work. Yet they were persuaded that the honor of the university called on them to be excused from constant attendance and regular duties as if in the public service; fed at double rates; trained to the verge of "staleness"; portrayed more often than college presidents; wagered on like race horses; bathed and rubbed like cripples; attended by surgeons like duelists; nay, if experts are to be credited, occasionally disabled by methods as unfair and cowardly as those of the savage and the assassin. The university that shall first restrict football to its own members and grounds and abolish gate receipts, may lose some income and a few nominal students; but posterity will award it honor higher than for any other corporate achievement.—*Am. Medicine.*

the red light may soon be given adequate trial on a large scale, so that its real merits may be determined more definitely. Finally, it may be well to emphasize again that it is not now here claimed that red light prevents suppuration even when used as outlined by Finsen, but it is claimed that, so far, in this country, the treatment has not received such trial that we are in position to say that Finsen was wholly deceived as to its value under the restrictions by him outlined. In justice to smallpox patients, new investigations should be instituted.

ANEMIA IN PORTO RICO.

In February, 1904, the legislative assembly of Porto Rico authorized the governor to take steps to encourage the study and cure of "tropical anemia" in Porto Rico. For this commendable purpose $5,000 was appropriated. A commission was appointed, composed of Bailey K. Ashford, captain, assistant suregon, U. S. Army, who really was the first to show that the tropical anemia in this island is due to hookworm; W. W. King, passed assistant surgeon, U. S. Public Health and Marine-Hospital Service; and Dr. P. G. Igaravidez, health officer of Bayamon, Porto Rico. A tent hospital was erected at Bayamon near San Juan in which treatment was begun in March last year and continued until April 30, when no less than 951 cases of anemia had been treated; in 947 the uncinaria was present as practically the sole cause of the anemia. The hospital was now moved to Utuado, and no sooner were the tents pitched than patients began to arrive in large numbers. At times, from 300 to 600 patients presented themselves in one day. By August 15, 4,543 cases of uncinariasis had been treated. In this way the commission gathered the material necessary for study at the same time that the treatment instituted by its success drove out the well-nigh universal skepticism in Porto Rico regarding the curability of the disease. Such, in brief, were the operations of this commission whose report was published Dec. 1, 1904.[1] Certainly the commission merits the highest commendation for its arduous labors and its prompt and valuable service. The value of its work to the people of Porto Rico can not be estimated. Hundreds and thousands of human lives have been made happier and longer as the direct result of an expenditure of $5,000!

The main results of the investigations of the commission which have been anticipated somewhat are that the anemia of Porto Rico, which affects about 90 per cent. of the rural population of the island, and is marked by profound anemia and chronic invalidism, is due to uncinariasis, and that the disease in the great majority of the cases is curable and preventable. In the treatment the essential feature, of course, is the expulsion of the worm. Three drugs merit serious mention: thymol, male fern, betanaphthol. We can not here enter on details of the treatment. Thymol was used with satisfactory results. Betanaphthol, introduced in the treatment of uncinariasis by Bentley,[1] was used toward the end of the work. Except for causing some dizziness, the commission regards this drug, which is only one-tenth the cost of thymol, as an ideal vermifuge in this disease, destined to eclipse thymol and male fern. For the many valuable observations on various features of the disease, such as the mazamorra or uncinarial dermatitis caused most likely by the penetration of the skin by the larvæ in infected soil and water, the diagnosis by examination of the feces, the remarkable eosinophilia, the suggestions in the line of prevention, etc., reference must be made to the full report which will always constitute a landmark in the history of uncinariasis. It is hoped that this report will prove stimulating to the study and cure of anemia in the lower classes in other tropical countries. The day of blind reliance on iron, quinin and tonics in general in the treatment of anemic conditions in tropical countries is past, never to return. Treatment must be directed against the cause and, in the case of uncinariasis, the specific cause is not difficult to find and to remove. Undoubtedly, Porto Rico will continue the humanitarian work, so well commenced, to the end that another preventable disease will be prevented in fact as well as in theory.

THE LYMPHOCYTES IN TUBERCULOUS INFECTIONS.

The relation which exists between certain forms of bacterial infection and the increase in certain varieties of leucocytes in the blood has been known for many years, and has been taken advantage of in diagnosis. We know that septic infection is generally associated with a polynuclear leucocytosis, that in typhoid fever the mononuclear leucocytes are relatively increased, and that infection with intestinal parasites often causes eosinophilia. In recent years, the use of cytodiagnosis has brought out the fact that tuberculous effusions usually show an excess of lymphocytes, and has suggested that the tubercle bacillus elaborates a poison which is positively chemotactic to lymphocytes.

This suggestion is not a new one; in fact, a number of observers have claimed a lymphocytosis following the use of tuberculin. These observations are not numerous, and recently Fauconnet[2] has deemed the subject worthy of more extended investigation. He states that in the early stages of tuberculosis the blood is unchanged, and that his main aim in his experiments was to find out whether a sudden flooding of the body with tuberculous toxins would lead to recognizable changes in the blood. He first took cases in the early stages of tuberculosis and injected them with tuberculin, examining the blood before and after the injection. He found that in all these cases there was an immediate increase in the leucocytes, the average increase being 2,000 leucocytes per cubic millimeter. It was the polynuclears which were increased, however, and not the lymphocytes. After a few days the leucocytes were slightly decreased, but the relative increase in polynuclears persisted. The examination of the blood and also of the exudate, in several cases of serous-membrane tuberculosis with effusion, showed that while the lymphocytes predominated in the effusion their number in the blood was not increased. The experimental injection of healthy guinea-pigs with tuberculin gave less positive results. In all cases there was a leucocytosis, but in some the polynuclears were increased, while in others the lymphocytes were the cells affected. In guinea-pigs, which had been injected for a long time with tuberculin, there was a decided increase in the lymphocytes. Fauconnet does not regard this as a chemotactic phenomenon, though he does not give any adequate reason for this standpoint. The effect of introducing capillary tubes beneath the skin of guinea-pigs after filling the tubes with tuberculin differed according to the strength of the tuberculin. Strong tuberculin led to destruction of leucocytes, but when these were preserved it was always the polynuclears which wandered into the tubes. The same results followed the introduction of tuberculin directly into the peritoneal cavity, the cells found in the exudate were polynuclears.

---

[1] Report of the Commission for the Study and Treatment of Anemia in Porto Rico, San Juan, P. R.

[1] Indian Medical Gazette, 1904, vol. xxix, No. 1.
[2] Deutsches Archiv für klin. Medizin, vol. lxxxii, Nos. 1 and 2.

Fauconnet concludes as a result of these experiments and clinical observations that the tubercle bacillus, like most other bacteria, possesses chemotactic power only over the polynuclear leucocytes, so that, as far as the blood is concerned, we can expect no changes which will be of diagnostic value in the early stages. So far as the presence of cells of the lymphocyte type in tubercular effusions and in tubercles themselves is concerned, Fauconnet thinks that their presence is not explained by chemotaxis. In the case of the effusions into serous cavities, he thinks that the close relation of the serous cavities to the lymphatic system may explain the excess of lymphocytes. Fauconnet's work is mainly of negative value, as it shows that little is to be expected from the blood examination in the early stages of tuberculosis; it upholds, however, our present views regarding the character of the cells in tubercular exudates.

TRUTH AND POETRY CONCERNING URIC ACID.

V.

Mares' hypothesis assumed that all uric acid excreted comes from the nucleins of the cells of the body; it denied any direct origin from the nucleins of the food.

The incorrectness of this assumption has since been shown by many researches. Thus it was soon demonstrated that foods rich in nuclein or in xanthin bases exercise a powerful effect on the excretion of uric acid (Horbaczewski, Richter, Weintraud, Lütje). A difference, however, in the action of the nucleins of individual foods is discernible. Umber showed that while the feeding of thymus and liver increases uric-acid excretion, the feeding of brain and kidney, which are almost equally rich in nucleins, does not increase it, at any rate to the same extent; the mode of chemical union in the various nucleinic acids, therefore, Umber thought, can be of great importance. Similar experiments were made by P. Mayer, Jakob and Bergell, Rosenfeld and Orgler, Carlyle Pope and Minkowski. It must be considered as established that nuclein in the food can increase uric-acid excretion.

Despite these researches, the reason for increased uric-acid excretion after the eating of meat still remained obscure, for meat, Kossel showed, contains but little nuclein; further, it had already been proved that there is no direct relation between albumin intake and uric-acid excretion. That meat eating does significantly increase the uric-acid output had been repeatedly demonstrated (Strauss, Smith and Jerome, Zagari and Pace. Sivén). The explanation came with the discovery by Kossel of the existence of an abundance of free xanthin bases in meat, and with the bringing of the proof by Burian and Schur, that of the 0.06 per cent. of purin bodies present in meat, no less than 0.045 per cent. are in a free state. If free xanthin bases can give rise to uric acid, as would seem probable, since the synthetic studies of Emil Fischer have shown their near relations to one another chemically, the increased uric-acid excretion after meat eating is easily accounted for.

And yet, the older experiments, it will be recalled, indicated that the feeding of free xanthin bases alone does not increase uric-acid excretion. It was time that that observation should be subjected again to an experimental test, and this work was undertaken by Minkowski.[1] His studies showed that the feeding of xanthin bases, especially hypoxanthin, leads in man to marked increase of uric-acid excretion. The earlier experiments, which had been negative, had been made chiefly on dogs; Minkowski discovered that in the dog the xanthin bases fed are excreted not as uric acid, but as allantoin; this explains how the idea had arisen that the feeding of xanthin bases does not increase uric-acid excretion. This proof of the possibility in man of a direct transformation of the xanthin bases of the food into uric acid independently of any intermediation of the leucocytes of the body, marks the next important step forward in the progress of knowledge in connection with our subject.

It had by now become perfectly clear that the uric acid excreted can be derived from at least two sources—first from the nucleins of the cells of the body itself, and second, from the nucleins and xanthin bases of the ingested food. From this time on, it became customary to speak of the excretion of "purin bodies" (xanthin bases plus uric acid) in the urine, rather than simply of the excretion of uric acid. Burian and Schur[2] refer to that portion derived from the metabolism of the body cells as "endogenous" urinary purin bodies, and to that portion derived from the nuclein and xanthin bases of the food as "exogenous" urinary purin bodies.

---

[1] Minkowski, O.: Ueber den Einflus der Leber-Exstirpation auf den Stoffwechsel, Arch. f. exper. Path. u. Pharmak., vol. xxi, 1886, p. 89; Untersuchung zur Physiologie und Pathologie der Harnsäure bei Säugetieren, ibid., vol. xli, 1898, p. 375.

An interesting attempt was made by Burian and Schur to determine more exactly the actual relative amounts of endogenous and exogenous purin bodies. They believed that by estimating the purin content of the urine of well-fed human beings, whose diet was kept free from purin bodies, that they had determined the amount of endogenous purin bodies excreted. Their findings indicated individual differences for this value. The increase in the amount of purin bodies excreted when nucleins or xanthin bases are fed to the same individual indicates, they thought, the amount of exogenous purin bodies excreted. The latter amount, they believed, is dependent wholly on the quantity and quality of purin bodies fed. They asserted that 50 per cent. of the hypoxanthin ingested as food (either free hypoxanthin or that combined in nuclein) is given out in the form of purin bodies in the urine, while only 25 per cent. of the adenin ingested is excreted as urinary purin.

Extremely valuable as have been the contributions of Burian and Schur to the physiology and pathology of uric-acid excretion, they have, it appears, gone too far in their later assumptions. The matter is not so simple and diagrammatic as their work would lead us to believe. Some of the objections to their views have been well formulated by O. Löwi.[3] He points out that it is really impossible by our present methods to determine accurately how much of the purin bodies excreted is endogenous and how much is exogenous in origin.

In all probability, the endogenous purin bodies can be derived from several different sources. Thus under physiologic conditions it seems probable that in mammals they are derived chiefly from the nuclein metabolism of all the body cells and, principally, of those body cells which undergo most active chemical changes, namely, the cells of the secreting glands and of the muscles. A further possible source of endogenous purin bodies, even in mammals, is by way of direct synthesis. So much attention had thus far been directed to the origin of uric acid by the oxidation of complex compounds that but little consideration had been given to the possibility of its formation in the organism by the union of simpler bodies. We shall turn in our next article to a consideration of the possibility of such a synthetic origin of uric acid.

A NOTABLE ACHIEVEMENT.

A news item in The Journal, Feb. 4, 1905, deserves emphasis. Every reader of The Journal, every member of a local or state board of health, and, indeed, every American citizen should fully appreciate the fact that the Kentucky State Board of Health has succeeded in requiring all the railroads of the state to regularly disinfect all passenger cars. When the proposal first was made, the railroad officials smiled, but after they understood the powers of the State Board of Health they took the matter soberly and ended by agreeing to enforce the regulations regarding car sanitation and sterilization, that were published in detail in a former issue. This reform applies not only to cars used in short runs and in local service, but also to the sleeping, dining, buffet and parlor cars on the through trains which merely traverse Kentucky soil. If persistence and persuasion, supported by some show of authority, can accomplish this in Kentucky, what prevents other states from following this admirable example. Experiment and experience have shown that railroad cars frequently act as carriers of infection. Kentucky has shown how to meet this danger to the health of the community, and other states can not afford to be too far behind.

FIGHTING MEDICAL FRAUDS.

We have published in our news columns, from time to time, accounts of the measures adopted by our German confrères to fight medical frauds. It would be well if we would follow their example, and through our medical organizations institute more active proceedings against all sorts of irregular practitioners. Whether we can get the full co-operation of the public press in the work, as seems to be the case in Munich and in other German cities, may seem at first a little doubtful. But we believe that if the same methods were employed here they would be equally effective. It only requires a certain amount of effort on the part of the medical profession to persuade all respectable newspapers to exclude fake and fraudulent medical advertisements. So far as we know, however, we have nothing in this country exactly corresponding to the "press committees" of the Germans. If our county societies would take the matter up with vigor, a decided impression could be made on public opinion which would necessarily be followed by a great reduction in the ranks of medical pretenders and humbugs. An active committee, keeping the lay press properly instructed in medical matters, and unsparing in its exposures of fraud, wherever found, would work wonders. The public only want the truth and to be convinced that it is the truth, and the success of medical impostors would terminate. Let the medical profession make it clear that it has the real interest of the public at heart and the success of the movement will be certain.

A HANDBOOK ON THE PREVENTION OF CONSUMPTION.

The Committee on the Prevention of Tuberculosis of the New York Charity Organization Society has issued a valuable report entitled "*A Handbook on the Prevention of Tuberculosis.*" It contains, beside the usual review of the year's work and the financial report, a number of valuable papers on the various questions which arise in regard to tuberculosis, including essays on the social and statistical aspects of the subject, on the causes of consumption and on the proper methods of treatment; it includes elaborate plans for sanatoria, lists of institutions in the United States and Canada, and a bibliography of the principal works on tuberculosis. These appendices form the bulk of the volume, and their authors have done excellent work. One of the most interesting chapters is that on the social aspects of tuberculosis by the statistician of the committee. This chapter points out that special perils exist in cities rather than in the country districts, and that certain races and occupations appear to be specially liable. The conclusion is that we must look more and more to the apparently indirect methods of dealing with the disease. The report says: "The problem would soon disappear of itself if it were possible for everybody to breathe fairly pure air, to be clean with a reasonable effort, and to have enough of the right sort of food to eat." It will require a great deal more than is being done to bring this about, but that is the main line on which we will probably make our most effective attack on the disease. One thing is encouraging: statistics show that the mortality from consumption is decreasing, and that this decrease is more marked in just those localities where, at least, an approach to the necessary sanitary reforms is being made.

THE PAINS OF TABES.

As is well known, locomotor ataxia, while not of itself a fatal disease, is often attended with symptoms or complications of a most distressing and even serious character. Motor inco-ordination is not always the most conspicuous manifestation, and it may at times be so little marked as to escape cursory observation. Not less common than ataxia, and earlier in appearance, are pains of one kind or another, and which may at times be so severe as to dominate the clinical picture. They are often mistaken for rheumatism or gout or neuritis, but their real origin can usually be determined from a study of the other symptoms present in the individual case. Sir William Gowers,[1] in a recent clinical lecture, took up for consideration the pains of tabes, discussing at some length a condition to which he gives the name of tabetic neuralgia. He makes two divisions of the pains attending tabes, namely, those that are brief, commonly momentary, but succeeding each other at short intervals in the same place, for hours, sometimes for days; and those that are prolonged, lasting for hours or days or even longer in the same place. The first variety may be superficial or deep; those of the second variety are usually deep, although diffuse surface sensations of this character are not uncommon. In some cases of tabes, pain is the only prominent symptom, the knee jerks and co-ordination being preserved. Such cases are thought to constitute a special and uncommon variety of the disease and to be due to a peculiar character of the toxic etiologic factor; and for them the designation tabetic neuralgia is considered appropriate and unobjectionable. Eleven cases of this kind analyzed by Gowers all occurred in adult men, 9 of whom presented a clear specific history, which, further, could not be excluded in the remaining 2. The interval between the primary disease and the onset of the pain varied from seven to nineteen years, the average being twelve years. The knee jerks were normal in degree and equal on the two sides in 8 cases and unequal in 2; while in 1 the reaction disappeared entirely on one side. In 2 cases, the reaction of the pupils to light was absent; in 2 it was enfeebled; in 2 it was completely wanting on one side; and in 1 there was instant contraction followed by dilatation to its former size. One patient presented characteristic atrophy of the optic nerve, with preservation of the knee jerks, of co-ordination and of cutaneous sensibility. In one patient, sensibility to pain was lost on the feet and lower legs and lower parts of the thigh; in 1 it was delayed on the legs and lost on some parts of the trunk; and in 1 it was lessened on the left leg and foot. One patient suffered from gastric crises, and he and one other complained of girdle sensation. The pains were the symptom for which all of the patients sought relief, except the subject of optic nerve atrophy. They had been present in 3 patients for one year, in 1 for two years, in 3 for three years, in 1 for four years, and in 3 for ten years. They had variously been ascribed to gout, rheumatism and neuritis. From a prognostic standpoint the outlook is favorable with respect to the development of ataxia, but the pains, although their severity can often be mitigated, can seldom be altogether arrested. There is, however, no relation between the severity of the pain and the progress or the gravity of the underlying disease. The pains are believed to originate in the extremities of the peripheral nerves. The superficial pains can be relieved temporarily by the local application of chloroform sprinkled on lint and covered by oiled silk. A more prolonged effect is produced by the hypodermic injection of cocain at the upper part of the area in which the pains are felt. The sensibility of the skin to both touch and pain can be abolished by the application of the positive anode of a galvanic battery saturated with a solution of cocain of from 6 to 8 per cent. The deep, as well as the superficial, pains, as a rule, are amenable to treatment, and the coal-tar preparations are recommended. Sometimes morphin may be required, but it should be used with caution. To lessen the tendency to the occurrence of tabetic pains, Gowers has found aluminum chlorid, in doses of 5, 8 or 10 grains thrice daily, a most efficient agent. The salicylates, also, are sometimes useful for this purpose.

Medical News.

ALASKA.

A Summer Resort.—Sitka Hot Springs is soon to be opened as a health and summer resort. Drs. Henry W. Coe, Robert L. Gillespie and Walter T. Williamson of Portland, Ore., are interested in the venture and will spend about $20,000 in buildings.

ARIZONA.

County Physician Indicted.—As a result of its investigations, the grand jury of Cochise County found a true bill for manslaughter against County Physician Marshall D. Johnson, Bisbee, and he is held in bonds of $3,000.

---

[1] British Med. Jour., Jan. 7, 1905, p. 1.

Grand Jury Arraigns Officials.—The December grand jury of Cochise County alleges gross irregularities and willful violations of law in the conduct of county institutions; finds the food provided at the county hospital insufficient in quantity and inferior in quality; the bedding filthy; the steward, brutal and abusive, and the county physician neglectful of his duties.

New Officers Elected.—At the annual meeting of the Yavapai County Medical Society, held Dec. 10, 1904, the following officers were elected: President, Dr. John S. Barrett, Prescott; vice-president, Dr. Henry D. Thomason, U. S. Army, Whipple Barracks; secretary-treasurer, Dr. Clarence E. Yount, Prescott, and Drs. John W. Flinn and Samuel V. Fitzsimmons censors.

ARKANSAS.

Medical Building Assured.—The Medical Realty Company has been incorporated at Little Rock, with a capital of $50,000, to erect a three-story building 140x50 feet designed expressly for the use of physicians.

Federal Board Report Approved.—The Secretary of the Interior has approved the report of the Federal Medical Board in which 126 practitioners are placed on the registered list of those entitled to prescribe the waters of Hot Springs.

Would Change Name.—In the biennial report of the Arkansas State Lunatic Asylum, the superintendent, Dr. Harry C. Stinson, Little Rock, recommends that the name of the institution be changed to the Arkansas State Hospital for Nervous Diseases. During 1903 146 patients were admitted, and in 1904 90, a total of 236 new cases.

Smallpox.—A death occurred at Warren, January 28, and several cases among negroes are reported.——The Argenta Board of Health has adopted a resolution requiring the employes of all stores, mills, factories and compresses to exhibit to their respective employers a certificate of vaccination. The police have been instructed to see that this resolution is complied with. There are now 60 cases of the disease in the city, principally among negroes.——Little Rock has at present 15 cases.

CALIFORNIA.

Hospital Notes.—A hospital is to be erected in Los Angeles to cost $35,000, for the exclusive use of Mexicans of the laboring class.——The reconstructed Children's Hospital at Los Angeles was formally reopened January 28.——By the will of the late Winifrede Martin, Los Angeles, nearly $80,000 is devised to charitable institutions, including several hospitals.——The trustees of the Samuel Merrett Hospital Fund, which now amounts to $630,000, have filed a petition asking that they be allowed to build part of the hospital at Oakland, to cost $75,000, as provided in the will of the late Mrs. Catherine M. Garcelon.

Under the Ban.—"Dr." James McLean, Los Angeles, was fined $100, January 3, for practicing without a license.——"Dr." C. A. Richmond, San Francisco, was fined $100, January 17, for practicing without a license.——"Dr." Edward H. Diehl, East Los Angeles, pleaded guilty, January 21, to practicing without license and will be sentenced.——"Dr." Charles Scavazzo, Los Angeles, was found guilty, January 17, of practicing without license and fined $100.——A jury in Sacramento on January 26 disagreed in the case of T. Wah Hing, holder of an alleged Hongkong diploma, who, it was proved, practices medicine and advertises himself as a practitioner.

Personal.—Col. Alfred C. Girard, U. S. Army, has been offered the superintendency of the Children's Hospital, San Francisco, to become effective on his retirement from the service in July, and has accepted the position.——Drs. William J. Walsh and James B. Hannah, inspecting physicians of the San Francisco Board of Health, have resigned.——Dr. Palmerston C. Campbell, Point Richmond, has been appointed lieutenant-colonel on the governor's staff.——Dr. James R. Curnow, San Jose, has been adjudged insane, and was committed to the Agnew State Hospital for the Insane, January 28.——Dr. Pavlo De Vecchi, San Francisco, has been honored by the King of Italy with the title of commendatore of the order of the crown of Italy.

ILLINOIS.

Smallpox.—There are said to be 25 cases of the disease in East Smithfield, Ill.

St. Francis Hospital, Evanston, during 1904, treated 212 cases, 23 of which were of appendicitis.

Guilty of Abortion.—Dr. Wade D. Stevens, Paw Paw, was found guilty of performing a criminal operation and will receive an indeterminate sentence, unless the new trial, which he is attempting to obtain, is granted.

Joint Meeting.—Winnebago County Medical Society and the Central Wisconsin Medical Society held a joint meeting in Rockford, January 31, followed by a banquet, over which Dr. Walter B. Helm presided as toastmaster.

Changes in Sanatorium Bill.—As the result of a conference of Hon. Edward J. Glacking, who introduced a bill for the establishment of a state sanatorium for consumptives, and Dr. James A. Egan, secretary of the State Board of Health, many minor changes will be made in the bill, although its main provisions remain unchanged. The county and district medical societies of the state will be invited to co-operate in the movement and will be asked to interest the representatives from their respective districts in this bill.

Chicago.

Hospital Purchases Site.—Chicago Baptist Hospital has purchased for $37,500 the property it has occupied for many years at Thirty-fourth Street and Rhodes Avenue.

To Enlarge Building.—Passavant Hospital Association has been organized for the purpose of enlarging the building of Passavant Memorial Hospital. A building and lot have been donated, and about $30,000 additional is required for construction purposes.

White Cross First Aid.—The first of the series of public lectures under the auspices of the American White Cross First Aid Society was given by Dr. Nicholas Senn, in the public library building, February 3. Dr. Senn compared the work to be done by this society in time of peace to that of the Red Cross in time of war, and then spoke briefly on the first dressing of gunshot wounds.

January Deaths.—The death rate of January was at the annual rate of 14.70 per 1,000. Deaths from all causes numbered 2,487, 146 more than in the preceding month, and 126 more than for January, 1903. The chief contributing causes were pneumonia, 515; consumption, 272; Bright's disease, 183; violence, 175, and heart diseases, 164. Diphtheria caused 52 deaths; typhoid fever, 29; scarlet fever, 8; and smallpox 7.

Comparative Mortality.—The total of 530 deaths reported during the week, equivalent to an annual mortality of 13.88 per 1,000, are 28 fewer than reported during the previous week and 66 fewer than for the corresponding week of one year ago. Compared with that week, there were 10 more deaths reported from the acute intestinal diseases, 13 more from consumption, 5 more from measles, 6 more from smallpox and 7 more from whooping cough. On the other hand, there were 18 fewer from Bright's disease, 3 from bronchitis, 6 from cancer, 7 from convulsions, 6 from influenza, 12 from heart disease, 46 from pneumonia, 5 from scarlet fever, and 2 fewer from typhoid fever—the 3 deaths from this last-named disease being the fewest for any January week in twenty-three years.

MARYLAND.

Railway Hospital Open.—The Baltimore and Ohio Emergency Hospital at Brunswick has been formally opened.

Honor Grand Master.—The masons of Maryland are about to erect a monument to the late Dr. Charles H. Ohr, Cumberland, past grand master of the order.

Ancient History.—Dr. Bernard Steiner, Baltimore, read a paper on the life of Dr. James McHenry, January 30, before the Frederick County Historical Society. Dr. McHenry was on Washington's staff and was also secretary of war. Fort McHenry was named after him.

Baltimore.

Pneumonia Leads.—The deaths from pneumonia ran up to 31 last week, and only 23 were due to consumption.

Physician Non-suited.—Dr. George A. Strauss, who brought suit for $1,000 against the United Railway and Electric Company for alleged injuries in being thrown from a street car, failed to prove his case.

New University Journal.—There will be issued at the University of Maryland, about the first of March, a monthly medical journal, to be known as the *University Hospital Bulletin*, which will be edited by Dr. Eugene F. Cordell.

Personal.—Dr. W. Lee Howard has returned from Jamaica.——Dr. Hugh H. Young has been on a pleasure trip to Nassau, W. I.——Dr. Champe S. Bradfute, who disappeared from his home here on May 11, 1904, has returned. For five months his mind was a blank, and when he recovered his mind he found himself in Virginia. He expects to resume practice.

MASSACHUSETTS.

Fire at Sanatorium.—The New England Sanatorium at Stoneham was damaged by fire to the extent of $25,000, January 1. The medical staff and nurses succeeded in removing all the patients without casualty.

Bequests.—By the will of the late E. W. Corman, Boston, Harvard University and Massachusetts General Hospital are named as beneficiaries to the extent of more than a million dollars.——Lawrence General Hospital has been bequeathed $1,000 by the late George F. P. Dodge of Chicago.

Hospital Notes.—Brockton Hospital Corporation, at its annual meeting, elected Dr. A. E. Elliott Paine, vice-president. During the year the governor of the state presented to the corporation a fully-equipped surgical building, at an expense of about $25,000. Dr. Nathaniel C. King was added to the executive committee.——At the annual meeting of the staff of St. Vincent Hospital, Worcester, held January 19, Dr. John T. Duggan was re-elected chairman, and Dr. David B. Lovell was elected secretary.

Personal.—Dr. Timothy F. Daly, Lawrence, was given a chest of silverware by the Galen Medical Club, January 2.——Dr. Charles N. Raymond, Rehoboth, was murderously assaulted on January 1 by a Frenchman whom he had befriended.——Dr. Carl H. Eidam, Lawrence, has been appointed a member of the board of health.——Dr. Elliott Washburn has been reappointed chairman of the Taunton Board of Health.——Dr. Clarence B. Livingston has been appointed physician of District No. 1, Lowell.——Dr. Walter A. Smith, Springfield, has been appointed medical director of the First Brigade, M. V. M., with rank of lieutenant colonel.

MINNESOTA.

Hospital Incorporated.—Mennonite Hospital of Mountain Lake has been incorporated with a capital stock of $25,000.

Acquitted of Murder.—Dr. Rudolphe T. Germain, Barnesville, charged with murder in the second degree, was found not guilty, at Moorhead, January 16.

Personal.—Dr. Alexander J. Stone, St. Paul, has been reappointed surgeon general of the Minnesota National Guard.——Dr. George E. Benson, Minneapolis, has gone to Europe for six months.——Dr. Edward Benham, Amboy, has been elected physician for the seventh district of Blue Earth County.

State Aid for Local Laboratories.—The State Board of Health, at its meeting, January 31, passed a resolution to the effect that "when cities of ten thousand population or upward have established a laboratory within the state, which in the opinion of the State Board of Health is an efficient one, it may then be made a branch of the State Board of Health laboratory and receive financial aid from the state. The application for affiliation with the State Board of Health is to be made by the local board of health under the approval of its city council. The amount of state aid to be given such a laboratory is to be determined by the State Board of Health." Under this provision a branch laboratory will probably be established at an early date at Duluth.

MISSOURI.

Physician Imprisoned.—Dr. J. D. Todd, Richards, formerly a member of the legislature, who shot and killed R. T. Wall in May last, was found guilty of murder in the second degree and sentenced to imprisonment for twelve years in the state penitentiary.

School Children To Be Examined.—The 35 physicians recently appointed to examine school children in Kansas City commenced their work January 30. They will examine and report any case of communicable disease, but will not treat the children.

New Medical Practice Act.—The general assembly, now in session, is considering a new medical practice act, the essential feature of which is the provision that applicants for licensure must present a diploma from a reputable college before they will be admitted to examination.

Personal.—Dr. Leonidas H. Laidlaw, resigned as medical director of the Louisiana Purchase Exposition, Dec. 31, 1904.——Dr. Charles W. Chastain, Plattsburg, has been appointed physician to the state penitentiary.——Dr. R. Leon Hill, Boonville, has been made a member of the Cooper County Medical Board of Pension Examiners.——Dr. J. Phillip Knoche, Kansas City, has been granted the right to change the spelling of his name to Kanoky.

MONTANA.

Isolation Hospital Opened.—The new isolation hospital for Billings was opened, January 19, and Dr. C. B. Miller has been appointed superintendent.

Diphtheria Prevails at Slockett.—On account of the prevalence of diphtheria at Slockett, the Cascade County Board of Health has decided to turn the jail into a quarantine station, where all diphtheria patients will be left until danger of infection is removed.

State Board Report.—The biennial report of the State Board of Health shows that smallpox has been greatly reduced. In 1902 there were 764 cases in the state; in 1904, only 122. Diphtheria increased 141 cases, as compared with 1903; scarlet fever decreased from 339 to 179, and there was also a decrease in typhoid fever cases of 42 for the year.

NEBRASKA.

Hospital Acquires Land.—The South Omaha Hospital Association has purchased two lots on which it proposes to erect a brick building to cost $25,000.

Physician Wins Suit.—Dr. Milton H. Everett, Lincoln, was given the decision in the suit brought against him for damages by reason of an operation alleged to have been unsuccessful.

Smallpox in Beatrice.—There are about 24 cases of smallpox in Beatrice, most of which are of a very mild type. The city council has passed an ordinance which provides a heavy fine for individuals violating the smallpox quarantine regulations.

State Capitol Insanitary.—A report has been made to the adjutant general that the Nebraska State Capitol, on which the state has expended $1,500,000, is in an insanitary condition, and is unsafe for the state officials whose duties compel them to remain in the building.

Personal.—Drs. John B. Lichtenwallner, Dunbar, and Will T. Neil, Nebraska City, have been appointed physicians of Otoe County.——Dr. James L. Alden, Pierce, will be superintendent of the new state hospital at Norfolk, when it is completed, and Dr. Frank S. Nicholson, St. Paul, will be assistant superintendent.——Dr. Artie Folsom, Beatrice, is now in London.

NEW YORK.

Fire in Hospital.—St. Mary's Hospital, Jamaica, L. I., narrowly escaped a serious fire. Through the efforts of one of the physicians and two attendants the flames were held in check until assistance arrived.

Influenza Among Life-Savers.—An epidemic of influenza prevails among the members of the Long Island coast life-saving crews. Some of the stations have more than one-half their members incapacitated. Hardships encountered during the recent storms are said to have aggravated the cases.

Medical Society of the State of New York.—This body convened at Albany on January 31, February 1 and 2. The officers for the ensuing year are: President, Dr. Joseph D. Bryant, New York City; vice-president, Dr. Herman R. Ainsworth, Addison; secretary, Dr. Frederick C. Curtis, Albany; treasurer, Dr. Ogilvie D. Ball, Albany.

High Death Rate.—The State Board of Health reports 141,564 deaths in the state during 1904, the largest number ever officially recorded. This is a death rate of 18.2 per thousand, as against an average of 17.2 for the past five years. Consumption caused 14,000 deaths, or about 10 per cent., and there were 8,000 deaths from pneumonia during the first five months of the year.

Tuberculosis Hospital a Success.—The first report of the state hospital for the treatment of incipient tuberculosis, which was established by an act of legislature at Raybrook, in the Adirondacks, was presented to the New York State Medical Society. Although the institution has only been open since July 1, 82 patients have been admitted, 11 have been discharged as cured, 19 have apparently recovered, in 34 the disease has been arrested and the remainder show improvement, with the exception of 5 who have not been there long enough to justify conclusions.

Duffy's Malt Whisky Declared Not Medicine.—The State Excise Department has won its case against a New York City druggist, the principal point involved being whether Duffy's malt whisky was a liquor within the meaning of the liquor tax law, or whether it was a patent or proprietary medicine, not subject to its provisions. At the trial in the lower court, the defense showed testimonials to the medicinal effects of the liquor, but the chemists, C. A. Crampton, chief chemist of the United States International Revenue Department, Joseph Du Guehuee, chief chemist of the Health Department of New York City, and Edward W. Wheeler, chemist for the State Agricultural Department, showed that the whisky contained 45 per cent. alcohol, and that it did not contain any appreciable quantity of any drug or medicine other than alcohol. The lower court gave a verdict for the excise department, declaring the $500 bond of the druggist forfeited for violation of his pledge not to sell liquor except on the prescription of a physician. The Appellate Division of the Supreme Court sustained this finding.

More Bills Before the Legislature.—Taxing Alcohol—A measure, interesting in view of the tragedy attending the adulteration of cheap whisky with wood alcohol in New York City, taxes all sellers one-third of the price of all alcohol sold, compels them to report to the State Department of Health monthly, and imposes a fine of $50 for each violation of the law.——To Change Management of State Institutions—A representative of the State Charities Aid Association has prepared a bill providing for the administration of the state insane asylums as it existed before the Odell régime. This means that local boards of managers are to be re-established for each institution, with full powers of supervision and control, aside from administering the finances of the institutions, which will be taken care of, as now, from Albany.——Optometry Bill—Efforts are being made by an organization of opticians known as the Optical Society of the State of New York to secure the enactment of a law to regulate and define the practice of optometry. With this object in view the optical society distributed to members of the medical profession 8,000 copies of a pamphlet entitled "Facts About the Optometry Bill," as well as copies to the state officials and members of the legislature and to all leading newspapers of the state. Following this it mailed subscription blanks to opticians asking for money contributions to defray the expenses of the campaign. The Medical Society of the State of New York will, through its committee on legislation, institute a vigorous opposition to the efforts of the optical society. The co-operation of the medical profession is solicited and the Opticians' League of the State of New York will join in the opposition, as they believe that the fitting of glasses for the relief of headache, dizziness, diplopia and other symptoms is no part of the work of opticians, but should be restricted to educated and licensed physicians.

New York City.

Gift to Academy of Medicine.—The complete collection of monographs possessed by the late Prof. Gerhardt has been purchased and presented to the library of the Academy of Medicine by Dr. A. Jacobi.

Fireworks Ordinance Shelved.—There has been an indefinite postponement of the hearing on the ordinance prohibiting the use of fireworks in this city. Many other cities have such ordinances and it is a source of regret that this city should neglect a matter which affects life and property to so great an extent.

Coroner Found Guilty.—Dr. Jackson, convicted on the charge of soliciting a bribe of $500 to clear "Dr." John W. Alexander, who was arrested on the charge of having caused the death of a woman by a criminal operation, has been found guilty. There is another indictment against him for having attempted to bribe the deputy assistant district attorney.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended January 30 389 cases of tuberculosis, with 167 deaths; 272 cases of diphtheria, with 40 deaths; 248 cases of scarlet fever, with 13 deaths; 174 cases of measles, with 7 deaths; 174 cases of varicella; 41 cases of typhoid fever, with 14 deaths; 8 cases of smallpox, and 28 deaths from cerebrospinal meningitis.

Order for the Health Board.—In the Supreme Court of Brooklyn an order has been granted directing the Health Board of the City of New York to show cause why a peremptory writ of mandamus should not be issued commanding the appointment of an assistant superintendent for the borough of Brooklyn. The Brooklyn assistant was removed last August, and druggists and others wishing to confer with the health board have been compelled to come to the central office in New York.

Free Meals for School Children.—The statement that there are 70,000 ill-nourished children in the schools of New York, many of whom are in the habit of coming breakfastless to school, led to a conference of the Charities Organization Society, the Society for the Improvement of the Condition of the Poor, the Children's Aid Society, and others, for a discussion of the subject. It was the consensus of opinion that there was no abnormal destitution nor that there were many children who were sent to school without breakfast because of the inability of the parents to provide for them. It was agreed, however, that there were many underfed children, and a committee was appointed to investigate and ascertain the real causes. The Salvation Army has already established several stations where breakfast is served to school children.

Special Courses Continued.—Cornell University Medical College will continue this year the courses instituted last season in lectures on special subjects connected with general medicine and general surgery. Drs. Charles L. Gibson, Ellsworth Eliot, Jr., and E. L. Keyes, Jr., will each give about six lectures on topics connected with general surgery. Drs. L. A. Conner, M. G. Schlapp, C. N. B. Camac and O. H. Schultze will lecture on topics connected with general medicine. Dr. John McGaw Woodbury, the present commissioner of street cleaning, has promised to deliver several lectures on municipal sanitation. These lectures are given to the third and fourth-year students and have been found of great value in the elucidation of subjects in which the lecturers have demonstrated their proficiency. At the same time they are of value to the faculty who are thus able to obtain knowledge of the latest advancement made in the college laboratories.

OKLAHOMA.

Change of Name.—The Protestant Hospital, Oklahoma City, has changed its name and will hereafter be known as the Oklahoma Hospital.

Personal.—Dr. Elmer E. Cowdrick, Enid, resigned as superintendent of the Territorial Board of Health February 1.——Dr. George A. La Motte, Oklahoma City, has been appointed physician of Oklahoma County.

Physicians Need Not Pay Fee.—The Territorial Board of Health and Medical Examining Board to-day lost an important case in the courts wherein is involved the payment of a $30 fee by applicants to practice medicine in Oklahoma. Physicians who have secured such certificates sued for the recovery of their fee and secured judgment. As the law has been in force for some time, the total fees to be returned to applicants aggregated a large sum. The board will appeal.

PENNSYLVANIA.

Named for Medical Board.—The governor has presented the following names to the senate for members of the State Board of Medical Governors, to serve three years: Dr. W. D. Hamaker of Meadville, and Dr. M. P. Dickeson of Glen Riddle, representing the Medical Society of Pennsylvania; Drs. J. C. Guernsey and Edward Cranch of Erie, Pa., representing the Homeopathic Medical Society; Dr. William Rauch of Johnstown, and Dr J. M. Louther of Somerset, representing the Eclectic Medical Society.

To Treat Consumptives.—A bill has been introduced in the legislature for the selection of a site and the erection of a state hospital for the treatment of incipient tuberculosis. The bill provides that the institution be located within the limits of the state forestry reservation in Franklin County. From 500 to 1,000 acres are to be set aside for the use of the institution. A commission of nine persons is created to select the site and to build the hospital. The commission is to be composed of the auditor general, the commissioner of forestry, the president of the senate, the speaker of the house, and three practicing physicians to be appointed by the governor, one senator, and one representative. The bill provides for an appropriation of $200,000. Patients who can pay for treatment will be required to do so by direct application to the board of trustees. Those who can not pay are to be admitted on the recommendation of county commissioners, directors of the poor, or the departments of charities of counties and cities.

Philadelphia.

Personal.—Dr. Alfred Gordon, on January 23, was appointed chief of the clinic of nervous and mental diseases in Jefferson Medical College Hospital.——Dr. Benjamin Horn and Dr. H. R. M. Landis have been appointed demonstrators of medicine in Jefferson Medical College.——Dr. John Kuestner sailed for Jamaica January 26.——Dr. S. Weir Mitchell has been selected to present the candidates for honorary degrees of the University of Pennsylvania on February 22. President Roosevelt will deliver the oration.——Dr. David L. Edsall and Dr. Alfred Stengel addressed the annual meeting of the Medical and Surgical Society of the District of Columbia in Washington, February 2.

GENERAL.

Life Insurance Statistics.—The report of the medical department of the Mutual Life Insurance Company of New York, in its sixty-second annual statement, shows that the total deaths exceeded those of 1903 by 434, the average age at death being 51.96 years. The classification of causes of death is interesting, owing to the presumption that policy holders are more careful of their health than others. This classification shows 510 deaths from organic disease of the heart; 504 from consumption; 477 from pneumonia; 438 from Bright's disease; 387 from apoplexy, and 112 from old age.

Nathan Lewis Hatfield Prize.—Five hundred dollars will be awarded by the College of Physicians of Philadelphia to the author of the best essay submitted on or before March 1, 1906, on "The Clinical and Pathologic Diagnosis of Sarcoma." Essays must be typewritten, designated by a motto or device, and accompanied by a sealed envelope bearing the same motto or device, and containing the name and address of the author. They must embody original observations and researches. The committee reserves the right to make no award if none of the essays submitted is considered worthy of the prize. For further information address Francis R. Packard, M.D., chairman, College of Physicians, 219 South Thirteenth Street, Philadelphia.

FOREIGN.

Mikulicz' Operation.—Von Eiselsberg of Vienna operated in January on Professor Mikulicz on account of an umbilical hernia. Recovery has been uneventful.

Influenza in Berlin.—The Public Health and Marine-Hospital Reports state that influenza is very prevalent in Berlin. The epidemic seems to be more virulent than usual, and a number of deaths have occurred.

Preventive Circular.—The faculty of the Budapest university has offered three prizes of $20 to $60 for the best article written in a popular style, designed to enlighten youth in regard to the nature, the consequences and the prophylaxis of venereal diseases.

Sleeping Sickness in a European.—Dr. C. França of Porto reports a case of trypanosomiasis in a man of 25 returning from Portuguese Africa after an absence of thirteen years. The subject had previously had malaria, beri-beri and blackwater fever. Trypanosomata were found in the blood.

Kaiserling Now a Professor.—Dr. K. Kaiserling was graduated only twelve years ago, and he has been privat docent and custodian of the pathologic museum at Berlin since 1901. He has now been made professor. In these few years he has won international fame by his method of preserving anatomic specimens in their natural colors. Some of his specimens have been on exhibition at all the large expositions of the last few years.

Death of the Improver of the Microscope.—E. Abbe died recently at Jena, aged 64. He was the inventor of numerous improvements in instrumental optics, and to him bacteriology owes its marvellous strides in late years He has been connected with the Zeiss factory, since 1860, and at the same time was honorary professor of astronomy and meteorology at Jena. His successful reorganization of the Zeiss establishment was on a basis which tends to solve some of the more pressing social problems of the day.

Medicine in the Prussian Budget.—According to our German exchanges, the Prussian government is much more liberal in its medical appropriations than is the case in this country. In the appropriations for the universities the effort is everywhere apparent to make practical use of the later achievements of medicine, some of which require costly equipment. In Berlin the new Polyclinic Institute for internal medicine is to be equipped with instruments and apparatus to cost over $5,000. The Anatomic Institute is to be enlarged at an expense of over $50,000, and about $25,000 is to be spent on the clinic for cutaneous and venereal affections, besides large amounts on other medical institutes, etc. For the campaign against trachoma this year nearly $88,000 has been again appropriated; $7,500 for research on foot and mouth disease; the same amount for the campaign against typhoid in the Trier district; $2,500 for cancer research, and $2,500 for the Berlin Cancer Hospital. A special laboratory is to be erected for Robert Koch, with $750 for its yearly maintenance. An innovation is an appropriation of $11,000 for supervision of harbors and shipping to keep out plague and cholera. New buildings are planned for seven university clinics and institutes, and a number of new assistants are to be appointed. Comparatively large amounts have been appropriated to bring the *x*-ray departments of the universities to a higher grade of excellence, and for the purchase of new instruments for the polyclinics, etc. A deficit of $52,400 at the Berlin surgical clinic is to be made up, and another at Göttingen of $7,500 and one at Marburg of nearly $1,400 in the ophthalmic clinic. The appropriation for postgraduate courses has been increased from $1,500 to $2,250.

Correspondence.

Panama—The Congress—The Canal.

Panama, Jan. 7, 1905.

To the Editor:—The fourth Pan-American Medical Congress was held at Panama, Jan. 2-6, 1905. In some respects Panama was a good place to hold a meeting. While geographically the country lies at nearly the hub of the western hemisphere, and is, perhaps, rather inaccessible to the majority of the represented nations, the congress was attended by representatives from Peru, Mexico, Guatemala, Nicaragua and Cuba, as well as from the United States.

As the specially chartered steamer *Athos*, which was unfortunately delayed and did not reach Panama until the afternoon of the last day of the meeting, carried some of the officers and about half those who attended, these physicians took no real part in the proceedings. Some papers of a thoroughly scientific nature were read, such as Frank's "Experiments and Experience in Liver Surgery," Senn's description of "Coxa Vara," Dr. W. C. Gorgas' résumé of "Sanitary and Hygienic Work in Havana," and Dr. Carlos Finlay's paper on "Sanitary Conditions in Cuba." The paper of Dr. Liceaga of Mexico, read by Dr. Ramon, gave the methods adopted by the Mexican government to stamp out plague in Mazatlan.

It was decided to hold the next meeting three years hence in Guatemala City, as this republic is very anxious to become the hostess. She has appropriated money for the purpose and promises to have ready the railway to the gulf, so that the journey from the United States will be comparatively easy. American delegates would have preferred the United States, Canada or Jamaica, but their opposition was not well enough organized to carry the point, and it is to be hoped that the expressed fear that the congress will become too Latin-American is unfounded.

Though Panama had little to show the visitors in the way of hospitals and laboratories, such as physicians usually expect in visiting foreign countries, there was the stupendous engineering problem involved in the construction of the canal, hand in hand with which goes the attempt to wipe out of existence the two diseases—malaria and yellow fever—which have hitherto been considered to be actually part of the soil and climate. In previous attempts at construction of the canal it was necessary to accept conditions as they were found, to dole out quinin, to treat individuals when they fell ill, and to give advice as to food, air and water. But here, for the first time, science is working on demonstrable medical as well as engineering facts. The microscope and instruments of precision are applied with as great accuracy as the steam dredge and there is a plan of sanitation as carefully outlined, estimated and undertaken as is the engineering plan itself.

Panama and Colon are probably the hottest places within the canal zone, while Culebra and Empire seem dryer and cooler. Panama has probably one or more cases of yellow fever nearly the whole year through, and to stamp it out of Panama, as has been done in Havana, the same methods must be adopted. Panama must be drained, the streets cleaned, and its houses fumigated. Colon must be equally well cared for and the whole canal area must be policed and inspected. Plans for this are already under consideration. The United States marines on the Isthmus live in barracks at Empire. They are picked men and are living under the strictest medical surveillance. Their food, water, clothing and hours of work and rest are rigidly controlled. They must be in bed at an early hour, they must sleep under mosquito netting, and they must take quinin. Even the better class of canal employes, the office force, have no such regimen. Each employe lives where he wishes or must, eats what he can get and exposes himself unrestrainedly. We wish to avoid the want and waste of the French, but not to fall into sinful economy, and to do justice to unacclimated employes a plain, comfortable barracks should be built on Ancon Hill or on the outskirts of Panama, where they not only may but must live. Some accessory zest and recreation such as clubs, gymnasiums and games should be added to the daily life of the employes to stimulate them to overcome the moral and physical enervation which has been so dreaded in tropical districts. The sanitary department is compelled to work under the old system of army contract surgeons, which may be well enough in its place, but on the Isthmus is not leading to the best results.

There were many excursions to various points of interest, two of the most enjoyable being to the island of Taboga, about eight miles across the bay, and to Culebra, where the practical and most decisive work on the canal is now in progress.

Albert B. Hale.

Fifty Consecutive Cases of Pneumonia Without a Death.

Scotland, Pa., Feb. 2, 1905.

To the Editor:—I just read with much interest the article by W. J. Galbraith, M. D., in The Journal, January 28, page 291, also the article by the same writer in The Journal, July 9, 1904, page 108. Dr. Galbraith has certainly been most fortunate in his treatment of pneumonia by the heroic use of sulphate of quinin, and he certainly deserves credit for the fearless expression of his convictions. With the march which this disease, "the captain of the men of death," is making annually, it is of the greatest moment that any successful manner of combating the power of the disease be recognized by the profession. With such apparently fortunate results by use of these large doses of sulphate of quinin that Dr. Galbraith reports, one naturally feels an honest desire to know whether this method might be the sheet anchor of the disease, or whether Dr. Galbraith was simply fortunate in the results. I am convinced that many members of the profession would be glad to read the opinions or conclusions of others regarding the probable success by this manner of using quinin in pneumonia.

John J. Coffman.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE ADMINISTRATION OF NITROGLYCERIN.

Rockport, Ky., Jan. 24, 1905.

To the Editor:—Referring to your editorial Oct. 22, 1904, on this subject, I find you state that von Noorden advises larger doses "than has hitherto been thought warrantable," stating that "when begun with small doses, as much as 1/6 gr., or even 1/5 gr. of nitroglycerin may be given in 24 hours." Please permit me to say, that in April and May, 1897, I began giving a man with chronic parenchymatous nephritis one drop of a 1 per cent. alcoholic solution of nitroglycerin (1/100 gr.) three times a day. I increased the dose as could be tolerated until more than 25 drops (1/4 gr.)—I do not remember just how much more, but more I know—were given three times a day (3/4 gr. a day). There were no bad effects at any time. Improvement and complete recovery accompanied its use.

I wish to say, also, that I dared to give these doses because of a case which I saw in Da Costa's clinic at Jefferson Medical College Hospital in October, 1888. A note made when attending these clinics reads: "Saw a young man on Oct. 20, 1888, who was taking 20 grains of pure nitroglycerin in 24 hours, for chronic parenchymatous nephritis, with good results and no bad effects. (See notes on clinics.)" This is no fiction. When the young man was presented, Dr. Stewart, chief of the clinic, read, "He is now taking 5 grains of nitroglycerin four times a day." Prof. Da Costa, interrupting, said, "You mean five hundredths of a grain." Dr. Stewart, blandly replied, "I mean five grains *of the pure drug*." Prof. Da Costa grew interested. Smilingly he said, "Let's see him take it." A dose of five grains was prepared in the presence of all. A sphygmograph was applied, and the dose was *administered*. Within less than three minutes the sphygmogram began to change in appearance. The effect, however, was not very great. The face flushed and the patient said there was just a slight fullness of the head. The records of Jefferson Hospital will corroborate me. And here is von Noorden, in 1904, saying that nitroglycerin may be increased in dosage to even 1/5 grain in 24 hours.

J. D. Maddox.

Answer.—In spite of the large *amounts* of nitroglycerin which can be given to animals without fatal result, medical men generally have been very cautious regarding its administration to human beings. This wariness is doubtless due to the fact that alarming symptoms are sometimes produced by relatively small quantities of the drug. A dose of 1/8 of a grain (2 1/2 gtt. of a 5 per cent. solution) has been known to cause vertigo and collapse. The literature indicates that when a patient begins with very small doses and gradually increases the amount, a marked degree of tolerance may be developed. The large doses referred to by our correspondent are truly remarkable, and would doubtless make even v. Noorden shudder. Our advice would be to go very slowly always until the tolerance in a given case has been made out. The main point to which we desired to draw attention by our editorial was the uncertainty of dosage of nitroglycerin in tablet form and the desirability of prescribing *it always in alcoholic solution*.

ANTIQUATED TEACHING IN MEDICAL COLLEGES.

A. B. C. writes that he can not agree with Dr. Leffmann's statement in The Journal of February 4, p. 405, "that few if any teachers at the end of twenty years can represent the existing state of their science." A. B. C. says that men such as Osler, Welch, Halsted, Remsen and Kelly, of Johns Hopkins, and instructors, equally as long or longer in practice, in such institutions as Harvard, Chicago, Columbia, Ann Arbor, Pennsylvania and other universities, not only represent "existing" science, but are compelled to do so or original research would not progress; in fact, that no teacher would be tolerated at the leading colleges for more than a semester if he did not represent the "existing state" of his science. A. B. C. says that the teacher to whom he referred in his first letter teaches the physiology of years ago, and *apparently knows nothing of electrotonus, or rather never mentions it in his lectures*; that he never speaks of the neuron doctrine, or of regeneration of nerve fibers from the separated *peripheral endings; that he attributes everything to "uric acid* diathesis," while such products of metabolism as leucin, tyrosin, xanthin, nuclein, hypoxanthin, etc., appear to be mere words to him; that adenin and guanin are unknown; that he never mentions Flechsig's association centers in his lectures on cerebral localizations; that he seems unaware of the importance of oxybutyric acid in diabetes; that he still teaches the old idea of leucocytes producing the blood plaques; that his lectures indicate that he knows nothing of the internal ferment of the pancreas, or the presence of cholin in the cerebrospinal fluid, or the derivation of cholin from lecithin; and that Foster's Physiology and Howell's American text-books are apparently unknown to him except by name. He adds: "If, as Dr. Leffmann says, the charge of being behind the times could be used to vacate most professional chairs, why, then, *I say*, they should be vacated. Would any university tolerate an 'antique' teaching the chemistry, physics or biology of twenty years ago? Would any of our schools of pure science retain *the teacher who teaches such physiology* as I have cited? Why, then, are our medical schools so complacent and satisfied with themselves?"

Marriages.

John K. Jamieson, M.D., Chicago, to Miss Ethel Gibson of Waukesha, Wis., January 19.

Andrew C. Lawrence, M.D., Baltimore, to Miss Rosa Levin, at Ellicott City, May 11, 1904.

Charles C. Britt, M.D., to Miss Esther Tracey, both of Conshohocken, Pa., January 26.

Fremont C. Knight, M.D,. Waukegan, Ill., to Mrs. Mary Holman, at Chicago, January 25.

Ralph S. Mitchell, M.D., to Miss Mabel H. Lucas, both of Eden Prairie, Minn., January 25.

Thomas S. Lippincott, M.D., Pottstown, Pa., to Miss Viola White of Mount Holly, N. J., January 30.

Frank G. Carlson, M.D., Thornton, Iowa, to Miss Mary Atwater of Iowa City, Iowa, February 1.

William Ford Ward, M.D., to Miss Winifred Belle Farrington, both of Binghamton, N. Y., January 26.

Edwin Lincoln Goss, M.D., Carrington, N. D., to Miss Nellie Della Standish of Sanborn, N. D., January 15.

Francis W. Drew, M.D., Ethel, Mo., to Mrs. Lorena Lillian Cross of St. Louis, at Macon, Mo., January 26.

Beverly Randolph Kennon, *M.D.*, Norfolk, Va., to Miss Ruth Alexander Ferebee, at Oxford, N. C., February 1.

Deaths.

William Johnston, M.D. Transylvania University Medical Department, Lexington, Ky., 1838, the oldest practitioner in St. Louis, and third of the quartette of octogenarians honored two years ago by the St. Louis Medical Society at a banquet, to die; president of the St. Louis Medical Society for several years, died at his home in St. Louis, January 31, from senile debility, after an illness of nine weeks, aged 90. Eight ex-presidents of the society acted as honorary pall-bearers.

Phillip Long Dieffenbacher, M.D. Jefferson Medical College, Philadelphia, 1855; a member of the American Medical Association; the oldest practitioner in Mason County, Ill.; assistant surgeon and surgeon of the Eighty-fifth Illinois Volunteer Infantry in the Civil War; president of the Mason County Medical Society, and member of the Illinois State Medical Society, died at his home in Havana, Ill., January 29, aged 74.

John H. Doughty, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1863; surgeon during the Civil War; health officer of Matteawan and Fishkill, N. Y.; for several terms president of the Dutchess County Medical Society, died at his home in Matteawan, January 28, from pneumonia, after an illness of four days, aged 74.

John Shore, M.D. Jefferson Medical College, Philadelphia, 1842, formerly a member of the St. Louis city council and board of health, and a pioneer practitioner of that city, died at his home in St. Charles, Mo., from catarrhal pneumonia, after a long illness, aged 85.

Frederick Otis Spooner, M.D. University of Vermont Medical Department, Burlington, 1892, of Sherburne, N. Y., died at Faxton Hospital, Utica, N. Y., January 30, a few hours after an operation for obstruction of the common duct, aged 38.

Mathew R. Hall, M.D. New York University, New York City, 1857, colonel in the Confederate service during the Civil War, died suddenly at his home in Warrenton, Ga., January 28, from heart disease, aged 62.

Henry Boynton, M.D., Vermont Medical College, Woodstock, 1852, surgeon during the Civil War; author and lecturer on historical subjects, died at his home in Woodstock, Vt., January 30, aged 81.

Charles C. Ellis, M.D. University of Vermont Medical Department, Burlington, 1867, died at his home in Somerville, Mass., January 28, from pneumonia, after an illness of two weeks, aged 57.

Eugene C. French, M.D. University of Michigan Department of Medicine and Surgery, 1882, died at his home in Orlando, January 26, after an illness of four years, from chronic bronchitis, aged 50.

Edward Linzee Cunningham, M.D. Harvard University Medical School, Boston, 1832, said to have been the oldest graduate of that institution, died at his home in Newport, R. I., January 29, aged 95.

John Bagby, M.D. University of Maryland School of Medicine, Baltimore, 1867, died suddenly from heart disease at the residence of his daughter in Lake Village, Ark., January 29, aged 61.

Henry C. Herring, M.D. University of Louisville (Ky.) Medical Department, 1859, died at his home in Lancaster, Ky., January 19, from septicemia, after an illness of three weeks, aged 72.

John M. Donlan, M.D. Harvard University Medical School, Boston, 1897, a noted athlete, died at his home in Fitchburg, Mass., from consumption, after a long illness, January 26, aged 31.

Walter Day Otis Kellogg Strong, M.D. University of Buffalo (N. Y.) Medical Department, 1847, died suddenly at his home in Fishkill Landing, N. Y., January 26, from heart disease, aged 81.

Jesse C. Waldo, M.D. College of Medicine, Syracuse (N. Y.) University, 1897, died at his home in Hulburton, N. Y., January 24, from pneumonia, after an illness of nine days, aged 32.

Jephtha Phelps Haynes, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1870, died at his home in Beaumont, Texas, January 26, after a long illness, aged 78.

Francis J. Lemoyne Johnson, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1897, died suddenly at his home in Washington, Pa., January 25, aged 33.

Samuel Johnson Mathews, M.D. University of Nashville, 1859-1860, died at his home in Mayfield, Ky., January 21, from septicemia, after an illness of seven weeks, aged 70.

Virgil W. Conner, M.D. Illinois, 1890, died at his home in Lansing, Mich., of which he was city physician for two years, from paresis, after an illness of one year, aged 57.

Lucinda Dille, M.D. Cincinnati, Ohio, 1855, medical missionary in Jamaica for three years, died at the home of her nephew in Red Oak, Iowa, June 17, 1904, aged 83.

James McElderry Mullikin, M.D. University of Maryland, Baltimore, 1842, died at his residence near Collington, Prince George's County, Md., February 1, aged 85.

Andrew H. Askew, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1869, died at his home in Harrellsville, N. C., February 1, aged 61.

John Stoddard, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900, died suddenly at his home in Silver Creek, Neb., January 30.

Louis De Plasse, M.D. University of Louvain, Belgium, 1866, died at his home in New York City, January 24, from the effects of a runaway accident two years before.

William B. Squire, M.D. Cincinnati, 1857, surgeon during the Civil War, died suddenly from heart disease, January 28, at his office in Worthington, Ind., aged 74.

Dwight W. Chase, M.D. Jefferson Medical College, Philadelphia, 1846, formerly of Delphos, Kan., died at the home of his daughter in Salina, Kan., January 18.

Henry Vidal, M.D. University of Berlin, Germany, 1873, died at his apartments in Tacoma, January 21, from nephritis, after an illness of two years, aged 55.

Homer L. Bartlett, M.D. College of Physicians and Surgeons in the City of New York, 1858, of Brooklyn, died at Thomasville, Ga., February 3, aged 74.

Squire S. Dilley, M.D. Cincinnati, 1894, died at his home in Pemberville, Ohio, January 28, from pneumonia, after an illness of four days, aged 45.

William W. Wilson, M.D. University of Maryland School of Medicine, Baltimore, 1866, died at his home in Glenarm, Md., February 2, aged 78.

William A. Mitchell, M.D. Medical School of Virginia, Richmond, 1873, died at his home in Mangohick, Va., February 2, aged 63.

Callohill M. Stigleman, M.D. Medical College of Virginia, Richmond, 1857, died January 30 at his home in Floyd, Va., aged 75.

Jennie Low Lynch, M.D. New York City, 1897, died recently from pneumonia at the home of her mother in Liberty, N. Y., aged 40.

Andrew J. Wesco, M.D. Ohio, 1881, mayor of Seven Mile, Ohio, died at his home in that place, January 30, after a long illness.

Leonidas M. Jones, M.D. Ohio, 1857, died at his home in Brooklyn, Mich., from senile debility, January 30, aged 82.

State Boards of Registration.

COMING EXAMINATIONS.

Kansas State Board of Medical Registration and Examination, Topeka, February 14-15. Secretary, G. F. Johnston, M.D., Lakin.

Connecticut Medical Examining Board, City Hall, New Haven, March 14-15. Secretary, Charles A. Tuttle, M.D., New Haven.

Massachusetts Board of Registration in Medicine, State House, Boston, March 14-15. Secretary, Edwin B. Harvey, M.D., Boston.

Maine Board of Medical Registration, City Building, Portland, March 28. Secretary, Wm. J. Maybury, M.D., Saco.

Alabama Report for 1904.—Dr. W. H. Sanders, chairman of the State Board of Examiners, reports the written examinations held in Alabama during 1904. The number of subjects examined in was 10, and percentage required to pass, 75. The total number examined was 138, of whom 13 were undergraduates. One hundred and eighteen passed, including 4 undergraduates, and 20 failed, of whom 9 were undergraduates. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Medical College of Alabama, (1884) 90, (1892) 78, (1900) 96, (1901) 84, (1902) 87, (1903) 90, 91. In 1904 the grade of 77 was reached by three, 79 by one, 81 by one, 82 by one, 83 by four, 84 by two, 86 by three, 87 by two, 88 by one, 89 by three, 90 by two, 91, 94, 95 and 96 by one each.		

Tulane University	(1904)	79, 79, 81, 87, 89, 89, 90, 96
Chattanooga Med. Coll.,	(1902) 78, (1904)	78, 78, 80, 83, 84, 84, 84, 86, 91.
University of Tennessee	(1893) 80, (1904)	94, 95
University of Nashville	(1903) 88, (1904)	75, 76, 78, 86, 86

Maryland Med. Coll.	(1904)	51
Undergraduates		69, 60, 58, 71, 74, 69, 73, 63, 54

The general average of all representatives of the Medical College of Alabama who passed was 86.2; of Tulane University, 86.2; of Chattanooga Medical College, 82.6; of University of Nashville, 81.5; of Memphis Hospital Medical College, 81.9.

Arizona January Report.—Dr. Ancil Martin, secretary of the Board of Medical Examiners of Arizona, reports the written examination held at Phoenix, Jan. 2-4, 1905. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 80. The total number examined was 15, of whom 12 passed and 3 failed. The following colleges were represented:

College. PASSED.	Year Grad.	Per Cent.
Barnes Medical College	(1900)	80.5
Jefferson Medical College	(1903)	85
University of Iowa	(1900)	92
Illinois Medical College	(1901)	80
Cornell University	(1903) 89, (1904)	88
American Medical Missionary College, Chicago	(1901)	94
Bennett Medical College	(1895)	80
University of Southern California	(1904)	85, 81.6
College of P. and S., New York	(1888)	80.5
College of P. and S., Ontario	(1903)	89
FAILED.		
Illinois Medical College	(1901)	65.5
College of Medicine and Surgery, Keokuk	(1889)	50.6
Michigan College of Medicine and Surgery	(1902)	44

Association News.

Yellowstone Park—Portland Special.

A sufficient number have indicated their desire to take in the Yellowstone Park on the way to the next session of the American Medical Association at Portland to warrant engaging the park for the party. As indicated last week, the number will be limited to 250, and it will be well for those who intend to go to send in their names as early as possible. Mention of this special was made editorially in The Journal, January 28, and under "Association News" in last week's issue. Further information in regard to this and other trips will be published week by week as information reaches this office.

Bill to Incorporate the American Medical Association.

On February 2 Senator McComas of Maryland introduced in the senate the bill to incorporate the American Medical Association (S. 7040). It was read twice by its title and referred to the committee on the judiciary, which is composed of Messrs. Platt of Connecticut (chairman), Clark of Wyoming, Fairbanks, Nelson, McComas, Depew, Mitchell, Spooner, Bacon, Pettus, Culberson, Blackburn and Patterson. The introduction of the bill in the House was mentioned in The Journal, January 21, p. 227. The bill, therefore, is in both the Senate and the House.

The Senn Prize Essay.

The committee on the Senn Medal begs leave to call attention to the following conditions governing the competition for this medal for 1905: A gold medal of suitable design is to be conferred on the member of the American Medical Association who shall present the best essay on some surgical subject. The award will be made under the following conditions: (*a*) The name of the author of each competing essay must be enclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device. The title of the successful essay and the motto or device is to be read at the session at which the award is made, and the corresponding envelope is to be then and there opened and the name of the successful author announced. (*b*) All successful essays become the property of the Association. (*c*) The medal shall be conferred and honorable mention made of the two other essays considered worthy of this distinction, at a general meeting of the Association. (*d*) The competition is to be confined to those who, at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. (*e*) The competition for the medal will be closed on, and no essays received after, April 1, 1905. Communications may be addressed to any member of the committee, which consists of the following: Dr. James E. Moore, chairman, 704 Pillsbury building, Minneapolis; Dr. M. L. Harris, 100 State Street, Chicago; Dr. Floyd McRae, Atlanta, Ga.

NEW MEMBERS.

List of members for the month of January, 1905:

ALABAMA.

Mason, F. H., Brewton.
McDowell, Wm. P., Eufala.

ARIZONA.

Purcell, W. B., Tucson.
Rodgers, M. A., Tucson.

ARKANSAS.

Alexander, Frank Stan, Houston.
Baker, J. P., Morrell.
Counts, G. D., Wesley.
Hardin, A. E., Fort Smith.
Jordan, J. F., McNeil.
King, Marion N., Texarkana.
Moore, W. A., Hindsville.
Martin, J. E., Hindsville.
Neighbors, G. G., Warm Springs.
Paddock, C. B., Fayetteville.
Rieff, W. L.,
Stark, C. B.,
Throgmorton,

CALIFORNIA.

Anthony, R. Seldon, Fresno.
Burlew, Jesse M., Santa Ana.
Brink, H. O., Lakeport.
Blake, Wm. F., San Francisco.
Bertola, Mariana, San Francisco.
Benton, Julian J., Berkeley.
Bates, Homer O., Long Beach.
Brennan, T. F., San Francisco.
Clark, J. Emmet, Alameda.
Clark, John Ingram, Santa Ana.
deChantreau, J. D., San Francisco.
Day, Robt. V., Los Angeles.
Dawley, Chas. G., Los Angeles.
Franch, Chas. E., San Francisco.
Gerson, T. P., Los Angeles.
Hubbell, Geo. R., San Francisco.
Hull, Leonard C., Hollister.
Hastings, Hill, Los Angeles.
Inman, Thomas G., San Francisco.
Lartigau, August Jerome, San Francisco.
Leith, H. Ovonder, San Francisco.
Moulton, D. H., Chico.
Medlock, James Randolph, Santa Ana.
Moore, E. C., Los Angeles.
McCue, James Edw., San Francisco.
Ophuls, William, San Francisco
Perry, C. D., Fresno.
Plymire, A. G., South San Francisco.
Pryor, F. O., Scotia.
Phelan, Henry R., San Francisco.
Robarts, H. P., San Francisco
Rankin, J. E., Gonzales.
Reed, J. D., Covina.
Ritchie, A. M., Pacific Grove.
Shurtleff, F. C., Los Angeles.
Spalding, Alfred B., San Francisco.
Smith, R. K., San Francisco.
Thorpe, Lewis Sanborn, Los Angeles.
Thompson, Allen Milo, Sonoma.
Witter, G. F., San Jose.
Wilson, A. P., Los Angeles.
Wernigk, R., Los Angeles.

COLORADO.

Dyde, Charles B., Greeley.
Foster, W. C., Gulch.
Haggart, J., Durango.
Lathrop, H. R., Como.
Monroe, Duncan Daniel, Hillrose.
Midgley, Arthur E., Denver.

CONNECTICUT.

Beebe, George H., Guilford
Dumortier, Jean, So. Norwalk
Glynn, D. L., Portland.
Robinson, Paul S., New Haven
Stanton, T. Francis, Bridgeport
Turner, Arthur Robert, Norwalk

DISTRICT OF COLUMBIA

Heller, Joseph M., Washington
Karpeles, S. R., Washington
McLean, N. T., Washington.
Nichols, J. B., Washington.
Stitt, E. R., Washington.
Stromberger, Henry H., Washington.
Seibert, E. G., Washington

FLORIDA.

McKee, W. P., Eustis

GEORGIA.

Alexander, Geo. L., Forsyth.
Buxton, T. A., Girard.
Gostin, B. S., Macon.
Jeffords, H. M., Sylvester.
Tankersley, J. S., Ellijay.

IDAHO.

Cooper, A. J., Nez Perce.
Louis, J. D., Saint Anthony.

ILLINOIS.

Anderson, H. V., Westfield.
Brown, J. Archibald, Kankakee.
Burtt, A. S., Momence.
Benson, John P., Joliet.
Barton, Francis W., Danville.
Culter, F. O., Gibson City.
deTarnowsky, George, Chicago.
Ehle, C. E., Quincy.
Fitzpatrick, M. W., Decatur.
Fowler, J. V., Chicago.
Fantus, Bernard, Chicago.
Herzog, A. E., Ottawa.
Hedger, Caroline, Chicago.
Hartman, A., Chicago.
Hill, Chas., Chicago.
Hall, Geo. W., Chicago.
Hoiby, Chas. O., Chicago.
Ingalls, Frank M., Highland Pk.
Isaacs, L. J., Chicago.
Johnson, R. P., Chicago.
Jones, Walter C., Chicago.
Knox, William T., Manchester.
Kingsley, V. C. T., Danville.
Kurtz, Charles J., Chicago.
Kell, A. P., Kell.
Lovell, John Gibbs, Chicago.
McRoberts, Wm. A., Joliet.
Miller, David Warren, Gilman.
McCormick, Franklin L., Carthage.
Milligan, Geo. W., Edinburg.
McComas, George U., New Canton.
Munch, Louise L., Joliet.
McDonald, James T., Mattoon.
Miller, A. Merrill, Danville.
Malcolm, Janet, Chicago.
Mowry, A. E., Chicago.
McGown, Jno. D., Chicago.
Pollock, Arthur D., Rushville.
Porter, F. D., Chicago.
Rivard, Geo. J., Assumption.
Rhodes, S. Ora M., Bloomington.
Richter, Arthur J., Chicago.
Scheve, Elmer F., Mascoutah.
Servass, A. G., Havana.
Schoennesholfer, Wm., Lostant.
Smith, J. W., Cutler.
Smith, Orman E., Bushton.
Taylor, J. B., Bloomington.
Voight, C. B., Mattoon.
Wray, Austin L., Alexis.
Whitlock, C. E., Columbus.
Weir, Chas. F., Chicago.
Wassall, Joseph W., Chicago.

INDIANA.

Abel, O. E., Modoc.
Bird, Joseph E., New Albany.
Birchfield, James William, Guilford.
Berkley, A. L., Rensselaer.
Bulla, Joseph M., Richmond.
Courtney, Thomas E., Indianapolis.
Cluthe, Wm., Tell City.
Carter, La[illegible]
Collins, C. C., [illegible]
Coleman, [illegible]
Duncan, W. [illegible]
Gardner, Lucy Woodward, Bloomington.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Feb. 4, 1905:

Brechemin, Louis, Jr., asst.-surgeon, reports as on temporary duty as examiner of recruits. San Francisco since Jan. 18, 1905.

Owen, William O., surgeon, ordered to proceed from Fort Logan, Colo., to U. S. Army General Hospital, Presidio of San Francisco for treatment.

Girard, A. C., asst.-surgeon, granted thirty days' leave of absence with permission to apply for thirty days' extension.

Torney, George H., deputy surgeon general, ordered in addition to present duties, to take charge of chief surgeon's office, Department of California, during leave of the latter.

Hoff, John Van R., asst.-surgeon general, promoted colonel, to date from Jan. 19, 1905.

Davis, William B., deputy surgeon general, promoted lieutenant-colonel, to date from January 19, 1905.

McCulloch, C. C., Jr., surgeon, promoted major, to date from Jan. 19, 1905.

Halliday, Francis A., contract surgeon, left World's Fair grounds, St. Louis, January 27, for his proper station, Fort McPherson, Ga.

McMillan, Clemens W., contract surgeon, returned to duty January 26, at Fort Terry, N. Y., from leave of absence.

Whinnery, Jean C., dental surgeon, ordered from Vancouver Barracks, Wash., to Forts Walla Walla and Wright, for temporary duty.

Adair, George F., contract surgeon, left Fort Wadsworth, N. Y., February 2, on two months' leave of absence.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Feb. 4, 1905:

Miller, J., Jr., asst.-surgeon, detached from duty with marines on the Isthmus of Panama and ordered to the *Boston*.

McDonnold, P. E., P. A. surgeon, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Dispensary, Washington, D. C.

Webb, U. R., asst.-surgeon, ordered to the Bureau of Medicine and Surgery, Navy Department.

Elmore, B., A. A. surgeon, appointed A. A. surgeon from Jan. 24, 1905.

Ross, John W., medical director, retired, detached from duty under the Isthmian Canal Commission.

Smith, R. K., surgeon, detached from the Naval Recruiting Station, San Francisco, resignation accepted, to take effect February 28.

Means, V. C. B., surgeon, detached from the Naval Hospital, Philadelphia, and ordered to duty at the Naval and Marine Recruiting Station, San Francisco.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ending Feb. 1, 1905:

Brooks, S. D., surgeon, placed on waiting orders effective January 27.

Magruder, G. M., surgeon, granted extension of leave of absence for thirty days from January 22 on account of sickness.

Rosenau, M. J., P. A. surgeon, one day's leave of absence, Jan. 28, 1905, under Paragraph 189 of the Regulations.

Wickes, H. W., P. A. surgeon, granted leave of absence for one day, January 30. To proceed to Philadelphia and report to Surgeon Fairfax Irwin for special temporary duty.

Lavinder, C. H., P. A. surgeon, detailed as inspector of unserviceable property at the Purveying depot, New York.

Gwyn, M. K., P. A. surgeon, granted leave of absence for four months from January 19.

Long, J. D., asst.-surgeon, granted leave of absence for seven days from Dec. 21, 1904, under Paragraph 191 of the Regulations.

Robertson, H. McG., asst.-surgeon, granted leave of absence for six days from February 6.

Frost, Wade H., asst.-surgeon, directed to proceed to Baltimore and report to the medical officer in command for duty and assignment to quarters.

Mullen, E. H., asst.-surgeon, directed to proceed to New York (Stapleton) and report to the medical officer in command for duty and assignment to quarters.

Linley, W. J., A. A. surgeon, Department letter of Jan. 3, 1905, granting leave of absence for thirty days from Jan. 16, 1905, revoked.

Moncure, J. A., A. A. surgeon, granted leave of absence for thirty days from February 1.

BOARD CONVENED.

Board convened to meet at the Marine Hospital, San Francisco, Feb. 1, 1905, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon W. G. Stimpson, chairman; P. A. surgeon J. M. Holt, recorder.

APPOINTMENTS.

Dr. Wade H. Frost, of Virginia, commissioned as asst.-surgeon in the Public Health and Marine-Hospital Service.

Dr. Eugene H. Mullen, of Maryland, commissioned as asst.-surgeon in the Public Health and Marine-Hospital Service.

RESIGNATION.

A. A. Surgeon A. C. Fraser resigned, to take effect Jan. 31, 1905.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Feb. 3, 1905:

SMALLPOX—UNITED STATES.

Arkansas: Jan. 21, Jacksonville, present; Helena, present; Little Rock, present; Lonoke Co., present; McAlmont, present; North Little Rock, present; Pulaski, present; Sweet Home, present; Ward, present; Wrightsville, present.

Illinois, Jan. 21-28, Chicago, 22 cases, 1 death; Danville, 3 cases

Kansas: Topeka, Jan. 21-28, 1 case.
Massachusetts: Boston, Jan. 21-28, 2 cases.
Mississippi: Gulfport, Jan. 20, 2 cases.
Missouri: St. Louis, Jan. 21-28, 20 cases, 4 deaths.
Ohio: Toledo, Jan. 14-28, 6 cases.
South Carolina: Greenville, Jan. 7-14, 5 cases, 2 deaths.
Tennessee: Jan. 21-28, Memphis, 12 cases, 2 imported; Nashville, 5 cases.

SMALLPOX—FOREIGN.

Brazil: Bahia, Dec. 1-31, 64 cases.
France: Paris, Jan. 7-14, 21 cases.
Great Britain and Ireland: Jan. 7-14, Belfast, 1 death; Dundee, 1 case; Hull, 6 cases; Leeds, 21 cases; London, 1 case; Manchester, 1 case; Newcastle-on-Tyne, 8 cases; Nottingham, 1 case; South Shields, 6 cases, 1 death; Glasgow, Jan. 13-20, 1 case.
Italy: Palermo, Dec. 24-Jan. 7, 31 cases, 6 deaths.
Norway: Christiania, Jan. 7-14, 10 cases.
Russia: Dec. 31-Jan. 7, Odessa, 2 cases; St. Petersburg, 7 cases, 2 deaths; Warsaw, Nov. 12-19, 1 death.
Spain: Cadiz, Dec. 1-31, 3 deaths.
Straits Settlements: Singapore, Dec. 24-31, 30 deaths.
West Indies: Island of Grenada, Dec. 29-Jan. 11, 4 cases.

YELLOW FEVER.

Mexico: Jan. 15-21, Merida, 1 case, 1 death; Tehuantepec, 1 case.
Panama: Panama, Jan. 25, 1 death.

CHOLERA.

Russia: Erivan, Dec. 21-28, 25 cases, 26 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Dec. 3-10, 1 case, 1 death

PLAGUE—FOREIGN.

Argentina: Santa Fe, Dec. 27, 1 death.
Australia: Townsville, Dec. 9, 1 case.
British East Africa: Port Florence, Jan. 1, 3 cases.
British South Africa: Durban, Nov. 27-Jan. 3, 1 case, 1 death
Egypt: Dec. 24-31, Port Said, 1 case; Suez, 7 cases, 4 deaths; Tukh, 5 cases, 3 deaths
Russia: Ural Territory, Dec. 26-28, 35 cases, 35 deaths.

Society Proceedings.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Dec. 14, 1904.

The President, Dr. Roland G. Curtin, in the Chair.

Differential Diagnosis and Treatment of Acute Pelvic Peritonitis Associated with Gonorrheal Salpingitis.

Dr. Brooke M. Anspach drew attention to the fact that while acute pelvic peritonitis of gonorrheal origin is best treated expectantly during the acute stage, it occasionally bears a close resemblance to acute appendicitis in which the expectant plan of treatment would be dangerous. The diagnosis is based largely on the *mode of onset*, the history of the patient and the presence of gonorrhea. Bimanual palpation in an initial attack of acute pelvic peritonitis due to the gonococcus is often negative because of rigidity of the abdominal walls and the slight structural change found early in these cases. After rest in bed, the use of salines, and hot applications to the abdominal wall, the symptoms subside in from three to ten days. At this time examination is painless, the structural lesions are plainly evident and operation should be performed. In case the expectant plan fails and the patient becomes progressively worse no time should be lost in opening the abdomen.

DISCUSSION.

Dr. Charles P. Noble said increased experience led him to expect less from conservatism in gonorrheal salpingitis than formerly. His views regarding operation in acute gonorrheal peritonitis coincided with Dr. Anspach's. He recalled having operated twice in the acute stage; one was a case of diffuse peritonitis; the other, of a large abscess to the left of the sigmoid. Both patients recovered. One case in which the result of conservatism was a good one was that of a young woman who had acquired gonorrhea, and in whom peritonitis resulted in the formation of an extra-peritoneal abscess. He operated in the acute attack, drained per vaginam, and the patient made an excellent recovery. The woman has since married and borne children. Unless the patient is a young woman, it is Noble's rule to take out both tubes, the uterus and ovaries. He has never seen a patient die of gonorrheal peritonitis.

Dr. John G. Clark said that the reason the gonococcus did not produce general peritonitis was because its chief habitat is the mucous membrane. As soon as the gonococcus leaves the fallopian tubes and enters Douglas' cul-de-sac, the peritonitis is merely toxic, due to the toxins of the gonococcus. He believes it unwise to operate during an attack of gonorrheal peritonitis. Illustrative of this he cited a case in which the symptoms had increased in severity and the question arose whether there was simply a gonorrheal peritonitis or involvement of the tubes and ovaries. Operation was done, the tubes and uterus being removed, and the ovaries left. Subsequently the woman developed a large abscess involving the ovary. Opening of the incision and further drainage were necessary. He emphasized the necessity of a close differential diagnosis and the importance of knowing when to wait until the acute attack had passed, and when not to wait but to operate for a more lethal type of infection. Dr. Clark believes in conserving all tissue possible, because the individual who usually contracts gonorrhea is a young woman. He feels that the conservative policy in some instances works splendidly, but in the majority of cases, badly.

Dr. Edward Martin said that his experience in this class of cases in recent years had been only as long as was requisite to transfer the patient to the hands of a competent gynecologist, but that in earlier days he had seen many such cases which had made a prompt recovery under conservative treatment of the acute attack.

The Significance of Abulic Symptoms in Cases of Mental Disease.

Dr. Robert H. Chase, superintendent of the Friends' Asylum for the Insane, Frankford, Philadelphia, stated that besides hysteria where it strongly prevails, abulia is common in all forms of nervous and mental disease in which the chief characteristic is a weakening or exhaustion of the mental processes. It is particularly conspicuous in melancholia, dementia præcox, and in the depressive types of general paresis; in some conditions of neurasthenia and psychasthenia; in the intoxication of opium and alcohol, and in the retardation of manic-depressive insanity. He divides it into systematized, localized and general abulia. Under the systematized he gives the abulia of sleep. Among the forms of general abulia was given the intellectual type, in which the trouble lies in a defect of the attention. He spoke of the rôle that attention played in the normal mechanism of the mind, and under the term aprosexia he gave its various defects in disease.

The Advisability of a National Department of Public Health and a Medical Cabinet Officer.

Dr. T. H. Evans said this was suggested by the late Dr. William Pepper. He favors it as a means to centralize and to render more effective the many interests of the country that are medical. The supervision of education of children, so as to suit individual tastes, needs and abilities, is indicated. Physicians ought to control all matters which concern the physiologic welfare of the citizen. The care of criminals, once apprehended by the law, belongs properly to medicine. Colonies for mental and moral degenerates, if established, would materially reduce crime. The physical defects of children should be understood as productive of later immorality, or conducive to it, if suitable education does not intervene. Education and licensing of practitioners of medicine and surgery belong to a central office, whose executive head should have a place in the cabinet of the President.

DISCUSSION.

Dr. Edward Martin thought that the question of education should be a matter of state control. In regard to criminals, imprisonment is not so much a punishment as it is a protection for the rest of the community. Too much leniency has been allowed criminals on a basis of mental defect. The idea of centralization is applicable to the subjects of sanitation and prophylaxis, particularly against contagious diseases.

Dr. Charles K. Mills believes that much could be accomplished by the establishment of a central health department of some description. He would be very glad to see the medical profession represented in the cabinet and believed much good might come from such movement. It might, however, be better if a department of science were created with bureaus of different kinds, including a national bureau of health which would unify methods concerning matters of health in all parts of the country. With such a national organization much might be accomplished in matters of quarantine, the pollution of rivers, the registration and examination of physicians, and such questions as physicians have the first right to consider. Those who have committed crime, if their mental and physical health is a matter of question, should receive that attention which is often not given them both before and after trial and after conviction. Such questions as the care of the insane, the care of epileptics, the commission of crime by the young, would receive more humane attention if there were some method of regulating their consideration, and if that method were, in part at least, national and centralized.

Dr. William S. Wadsworth said that questions which should come under the head of such a national executive department are the adulteration of foods, the study of sewage, the protection of life on railroads and in factories, child labor, the importation of hides and such materials, the quality of drugs and patent medicines. He regards as highly desirable the presence of a medical man in the cabinet.

Regular Meeting, held Dec. 28, 1904, at 8:30 P. M.

The First Vice-President, Dr. B. Franklin Stahl, in the Chair.

Food Preservatives and Food Adulteration.

Dr. H. W. Wiley, chief of the Bureau of Chemistry of the United States Department of Agriculture, said that the necessity of preserving food in some way had been recognized since man emerged from his savage state. The development of the science of chemistry had placed in the hands of the manufacturer the means of preserving food and the means of matching foods in tints and colors. He believes the education of the public in regard to artificial coloring of foods to be quite as effective as legislation. After Feb. 2, 1905, the food law will require that all food products entering this country artificially colored should bear a label so stating. The material for coloring need not be declared, except when sulphate of copper is used. His advice to food makers is to cease using colors, and especially if the coloring is under suspicion of any kind. Concerning antiseptics he believes that there never should be an antiseptic admitted to foods, except when absolutely necessary, or when ordered by the consumer. There is, he thinks, a legitimate use for sulphurous acid, as employed in the fumigation of dried fruits, and the burning of the sulphur match in wine barrels, but when it is used for preserving a poor wine, and for putting on the market a new wine before it is ripened, its use is unpardonable.

Defects in Pennsylvania Food Legislation.

Mr. W. W. Smithers said that the laws on this subject now being enforced in Pennsylvania are not the expression of the wishes of the people, and that they result in unnecessary interference with manufacturers and merchants. He advocated the repeal of the Act of 1895 and the enactment of laws based on the preservation of health and protection against fraud. He stated that the office of dairy and food commissioner is unconstitutional; that the existing food statutes are imperfect and open to many just complaints, and that every effort should be made to secure reasonable and adequate legislation on this important subject.

The Evaluation of Evidence as to the Pharmacologic Action of Food Preservatives.

Dr. Thomas Luther Coley stated that as an economic principle it is apparent that a nation of eighty million people could not be fed from the farm to the table or from the local abattoir to the table. There arises the complex problem of transportation of food in an edible condition. The use of chemical preservatives therefore becomes a necessity. Dr. Coley went over the grounds on which these are used, and reviewed the chief objections against their use. The dangers arising from reputably prepared food to which preservatives have been added, he said, are as nothing compared to the dangers from foods having undergone putrefactive changes. A problem of such importance should be settled by medical men and not by a lay jury in courts of law. Legislative enactments should not be made in advance of scientific knowledge. There must be disabuse of the mind of the criminality of intent on the part of reputable manufacturers and a sharp line should be drawn between adulteration and food preservation. The question to be decided is the action of very minute doses of food preservatives over a protracted period. In order to illustrate the faulty interpretations from research work undertaken on a wrong basis, Dr. Coley cited the papers of Pfeiffer, Kionka and Harrington dealing with sulphite of soda. In all these studies the amount of the drug used was higher than that employed for preservative purposes; too great quantities of meat were fed to the animals, and no variety of diet was allowed. Further, the animals were confined, of questionable health in the beginning of the experiments, and the deductions of these authors were not warranted so far as the use of sulphite of soda as a food preservative is concerned.

BUFFALO ACADEMY OF MEDICINE.

Regular Meeting of the Medical Section, held Jan. 10, 1905.

Dr. Allen A. Jones, Presiding.

The Treatment of Pneumonia.

Dr. DeLancey Rochester based his remarks on a series of 201 cases, with 16 deaths, a mortality of 8 per cent. Twenty-five of these cases were under 20 years of age; mortality, 4 per cent. Between 20 and 50, 115 cases, with 6 deaths; over 50, 61 cases, with 9 deaths. Rochester counseled against the early use of digitalis for the purpose of aborting the disease, because once the chill has occurred the disease is well established; and, furthermore, digitalis does not overcome the toxemia. In his opinion the Brand bath meets few of the indications. He does not use anti-pneumococcic serum because as manufactured in this country it is not reliable, and its cost is so high as to be prohibitive, in many cases. Creosote and guaiacol, used in large amounts by mouth and as an inhalation, are toxic and irritate the kidney, hence their use as stimulating diuretics is contraindicated. The nutrition is sustained by milk, raw eggs, plenty of fresh air and sunlight, and boiled or sterilized water. The toxemia is relieved by diuresis—induced by the administration of large amounts of milk and sterilized water; diaphoresis—hot mustard footbaths every four hours; catharsis—calomel followed by a saturated solution of Epsom salts. The mouth should be cleansed often by an antiseptic wash. The heart should be examined as often and as thoroughly as the lungs. It should be stimulated sufficiently early in the disease. For this purpose Rochester recommends strychnin—two milligrams every four hours, increased, if necessary, to four milligrams, every two hours; brandy—because of the ether it contains, and the carbonate of ammonia. To combat the pulmonary congestion, leeches and wet or dry cups are applied to the affected lung. Dry cups should be applied every four to six hours and kept on for one half hour each time. Rochester has been able to verify, post mortem, the value of dry cupping. He condemns the use of poultices, ice locally, and the old pneumonia jackets. He uses a light woolen jacket. The application of leeches and the ice bag over the precordium often will prevent a complicating pericarditis. Endocarditis may be combated by the hypodermic administration of nuclein. For the accompanying pleurisy, dry cupping, codein or morphin is given. If there is a pleural effusion, paracentesis is indicated, and empyema demands surgical intervention. In meningitis leeches are applied, sodium bromid is given and lumbar puncture may be done. With an enlarged right heart, frequent small pulse, arrhythmia, dyspnea and cyanosis the withdrawal of 10 to 16 ounces of blood from the median vein of the forearm will yield results in cases which other would prove fatal. In severe cases, hypodermoclysis is also of value. For prevention, the stools and urine should be disinfected; the mouth washed, frequently with an antiseptic solution and the sputum destroyed.

DISCUSSION.

Dr. Tartaro said he used the antipneumococcus serum prepared by Paul of Naples in three cases, and believes it to be of value. He said that the reason why the profession in this country has not had the good results reported by European physicians is because the serum manufactured here is not a good one.

Dr. Van Peyma strongly advocated plenty of fresh air.

Dr. Thoma saw no reason why strychnin should be used as a heart stimulant instead of camphor.

Dr. DeWitt Sherman prefers nitroglycerin because of its capillary dilating effect.

Dr. Blaauw expressed himself as being a believer in the efficacy of antipneumococcus serum.

Dr. J. Ullman stated that he had often noticed the excessive bleeding following the application of leeches. The salivary gland of the leech secretes a substance which prevents the coagulation of the blood at the site of the application of the leech, and it is possible that the beneficial result obtained from such applications is, in part, to be accounted for by the injection into the blood of an anti-agglutinating substance. The Germans have separated a leech extract by crushing the heads of the animals and making an emulsion in glycerin. The good results noted in normal saline hypodermoclysis may be explained by the anti-agglutinating effect of sodium chlorid.

Dr. Allen Jones deprecated the use of antipyretics because they crippled the heart by their depressant action.

Travel Notes.

AN INTERSEMESTRAL EXCURSION.

LEWELLYS F. BARKER, M.D.

CHICAGO.

(Continued from page 156.)

WÜRZBURG.

One of the most deservedly celebrated of the institutions of learning in Germany is the Royal Julius Maximilian University of Würzburg. Especially in medicine and in the natural sciences has this university a fair fame. It would be difficult to conceive of a better place for quiet work, for Würzburg is a small city of less than 80,000 inhabitants, beautifully situated among the vineyards in the valley of the Main, and the medical and philosophical faculties have for years included many of the most distinguished teachers and investigators in Germany. It was here that Emil Fischer did some of his best work on the synthesis of the sugars; it was in the physical laboratory nearby that Roentgen, in the course of his everyday work and in the middle of his otherwise relatively uneventful life, suddenly made that happy observation which set the world agog. The venerable v. Kölliker, who still lives in Würzburg, has given us an account in his autobiography of his own activities there. Boveri, the zoologist, has a world-wide fame; Medicus, Tafel and Manchot are names familiar to every investigating chemist.

The medical faculty is fortunate in having excellent laboratory buildings, beautifully situated on the Pleicher Ring and admirable clinical facilities in the large, well-organized, richly endowed Julius Hospital. Of the 1,400 students in attendance at the university last year, 461 were medical. The subjects of the first two years are extremely well taught, anatomy now under Stöhr's, physiology under v. Frey's, pathology under v. Rindfleisch's and pharmacology under Kunkel's direction.

Professor Stöhr, so well known to us in America through the translation of his admirable text-book, was called to Würzburg from Zürich and inherited the large modern Anatomical Institute from v. Kölliker. When an American enters the huge laboratories built for anatomy in Germany and in Austria, with their capacious and handsomely decorated entrance halls, their wide corridors, roomy amphitheaters, well-lighted dissecting rooms, elaborately organized study rooms and liberally outfitted research rooms for professors, assistants and advanced students, he realizes forcibly the advantages which accrue to the science in a country where for a long time it has been in the hands of men who have devoted themselves exclusively to it, and where it is studied for its own sake as well as taught to medical students as a foundation for their subsequent studies. In single institutions in America anatomy has been similarly recognized, living professorships have been established, adequate laboratories have been built, appropriations for staff and equipment have been made and work of the highest order is being carried on—but, in general, America has yet a long way to go in order to put this fundamental science on a level with that of continental Europe. But American universities and medical faculties seem to be wonderfully alive to the importance and needs of anatomy, and there seems every reason to believe that the excellent example set by a few of the leading institutions will soon be followed by the rank and file. And when this will have taken place, the European anatomists declare that they feel that they will be compelled to look to their laurels.

Stöhr's laboratory, so far as anatomic teaching (aside from research) is concerned, is one of the best organized I have seen. Here, if anywhere, one finds "anatomy made easy." Everything one can think of is done to help the student in his acquisition of the facts of the gross and the microscopic structure of the body. In the dissecting room, in the lectures, in the histologic laboratory, in the study-room and in the museum, no effort is spared that can contribute to the speedy, easy and accurate grasp of the multitudinous form relations which confront the beginning medical student in his study of the human cadaver. The leading principle with Stöhr (as with many modern teachers of anatomy), is that the student shall actually see as many structures as possible himself. And so he demonstrates *ad maximum*. In the lectures, the structures isolated by prosectors, are shown to the class; on the board careful pictures of the more important relations are drawn; on the walls are charts copied from the most accurate illustrations of current atlases. In the study room from day to day special demonstrations are made; special dissections or models of the same are exhibited, each part being ingeniously labelled for the occasion so that confusion of structures or names is scarcely possible; even the Steger models are placed beside life-size photographs of the same, each structure in the photographs being properly characterized by inscription in order to facilitate its recognition in the model.

A similar process of elaborate help is followed in the histologic instruction. With every section given out to the class for study a special demonstration is associated; in this demonstration a slide is placed under the microscope and beside it is a camera lucida drawing of the same field in which each structure has its appropriate legend. These drawings and legends are all controlled so that the student need not doubt their accuracy. In this way a difficulty is obviated—one which every teacher of histology who has had to deal with a large group of young assistants, has more than once keenly felt—I mean that of false instruction. Only too often does one find that a student who has applied to a young instructor for guidance has been led along a wrong path. The conditions in anatomic laboratories are such that young men with insufficient training have to be used as class-room instructors. Nothing is more discouraging to a student, or more likely to lead him to think a subject unimportant, than to find that the man who has been set to teach him can not tell the periphery of a lobule of the liver from its center, or the tractus solitarius from the descending root of the vestibular nerve. Much can be done to avoid the evil by systematic "instruction of the instructors" before the class meets. The real remedy is to furnish better trained instructors, and this will be possible when more money is available, when more men are drawn to the more purely scientific careers in medicine, and when the conditions become such that it will be possible to draw a sufficient number of instructors from a class of men who, beside having done the "required" work for medicine, have had a prolonged course in "non-required" advanced work. One of the things most needed now in American laboratories is provision for advanced anatomic work. The organization of a number of courses suited to those who, having taken the regular courses in anatomy in the medical school, desire to develop themselves more perfectly in the subject, would be hailed with gratitude by many. It should be possible for a gynecologist-in-training, for example, to find a well-planned advanced course on the anatomy of the organs of the female pelvis. Courses on the anatomy of the eye, of the ear, of the nose and throat, also might be especially organized. Such courses are already offered in a few institutions, it is true; but might they not advantageously be introduced in many more places? There is a field also for the working out of advanced courses in general anatomy and histology in which the student could repeat some of the work already done by great anatomic investigators. If anatomic curricula were thus enriched, marked progress ought to be made and real anatomic research should quickly be forwarded —much more rapidly, perhaps, than by setting immature intelligences at so-called "original work."

I have spoken of the immense amount of help given to the students in the department of anatomy at Würzburg. In connection with this and similarly organized laboratories it may be asked: "Is not too much help given? Is there not danger of 'spoon-feeding' there? Is it not true that it is only that which a student acquires with a certain amount of difficulty and personal exertion which he will retain? Does not such a method of instruction make too great demands on the time and energies of the teaching staff? Is it not possible that the research work of the professor and his assistants will suffer in laboratories where teaching is so highly developed?" These are questions which can scarcely be satisfactorily answered offhand; that they should be asked, it must be admitted, is natural. So much depends on the quality of the students to be taught and on the character and ability of the teaching staff, especially of the head of the department in each instance, that no answer can be given which would hold generally. It is probably safe to say that students can not be helped too much, provided they are always helped in the right way, and it is nearly always the right way when they are helped to learn how to help themselves. The sea of anatomy—if I may be permitted to make a time-worn figure do service once again—is too wide and the time for its exploration too short for the student's boat to be permitted to drift aimlessly about on its surface; the teacher must stand beside the student at the helm and teach him how to guide it; he must accompany him into the more important harbors, pointing out to him the best modes of approach, the channels which experience has proved to be the shortest and safest, the landmarks which serve as guides and the hidden dangers which threaten the passage of the novice. It is his duty as quickly as possible to make the apprentice so familiar with the apparatus of the ship, with the use of the charts and the books of other navigators that he may by himself, unattended by an experienced seaman, visit any known anatomic port. He will see that the learner does actually visit and observe all those more important harbors with which every well-trained medical man must perforce be familiar, and he will encourage him to explore thoroughly even the very smallest landing places in some selected region of the body which may especially interest him. For the study of the charts and the descriptions of the voyages of others alone will never make a navigator; the most complete familiarity with anatomic pictures and the most thorough learning by heart of anatomic descriptions can never take the place of personal work in the dissecting room and in the histologic laboratory. If in his training the student learns how many different kinds of vessels may be employed and how variously each may be worked, if he practices charting his different voyages for himself and becomes skilled in the keeping of a brief and accurate log, it should not take him long to acquire that degree of knowledge and skill which will afterwards be sufficient for him in his work. The majority of medical students will never in their subsequent careers make journeys in anatomy outside of charted waters; indeed, practical medicine and surgery has commerce as yet with only a small fraction of the termini to be found on the anatomist's maps, though every day some terminus, hitherto neglected, becomes important. But the good anatomic captain will see to it that his pupil knows which waters are charted and which are not; to impress the facts on the learner he will occasionally make a short trip with him into an unknown bay, feeling his way continuously as he goes, sounding here and calculating there, filling in a new area on the chart or correcting an old one; now and then, his heart will be gladdened when an adventurous spirit turns up in the crew, who, in love with the sailor's life, and not satisfied with repeating the voyages made by others, is fired with the ambition to travel on and on into the unknown—a new anatomist may develop with the strength and courage to lay out his own course.

Professor Stöhr is ably supported by two associate professors, Oskar Schultze and Johannes Sobotta, both of whom are known to American medical men, the latter through his embryologic studies and his atlas of anatomy just published in Lehmann's series. Though Schultze's studies, notably those on the nature and origin of the peripheral nerves, have apparently led him temporarily into false paths, his work as a whole is most promising, and he is generally regarded as one of the very best of the younger school of German anatomists. Sobotta's new atlas, it must be admitted, is somewhat disappointing; moreover, it was scarcely needed, the field being sufficiently filled, for the present at least, by the magnificent anatomic atlases of Spalteholz and Toldt. Men with investigative power are so uncommon that the spending of their time in the unnecessary multiplication of text-books is deplorable.

The department of physiology in Würzburg is now one of the strongest in the institution. Under the direction of von Frey, so long associated with the distinguished Ludwig in Leipzig, this is no surprise. A most painstaking, reliable investigator himself, von Frey has understood how to attract to his laboratory a number of other investigators, among them men who stand in the front rank in contemporary physiologic research. The physiology building is excellently suited to its purpose; the equipment is adequate and the yearly budget relatively liberal. The teaching is carried on by means of lectures and laboratory work, the latter being made a main feature, Professor von Frey having been one of the first to introduce into Germany the admirable methods of practical physiologic instruction which had their origin in the medical schools connected with American universities, and which, among others, Porter of Harvard and Howell of Johns Hopkins have done much to develop and to systematize. Von Frey himself has a leaning toward mathematics and physics; excellently trained in these basal sciences himself, his original researches have enriched physiologic knowledge mainly along physical lines. I need only refer to his exquisitely delicate investigations into the nature of the functions of the sense organs of the skin, including his establishment of the spatial independence of the organs underlying the sensation of pain from those underlying the sensation of touch, and to his many contributions to the methodical and graphic study of the circulatory apparatus, to recall to American physicians the importance of his work.

Mention was made above of the high grade of physiologic investigators who have been attracted to v. Frey's laboratory. The most brilliant, perhaps, of these is the young Englishman, Overton, who, though academic positions have been offered him, prefers to keep himself unentangled from teaching responsibilities in order to devote his undivided attention to the labor of original research. His studies of the mode and action of narcotics, begun with Hans Meyer, the excellent pharmacologist at Marburg, have been most far-reaching in their results. No better example, perhaps, could be brought forward of how work begun on a specific problem in a limited field may suddenly widen and permit of unexpectedly broad applications. Meyer and Overton began by asking themselves, How do narcotics act? The researches undertaken soon led to the putting of the more general question, How do substances of the most various sorts enter the cells of the body? Any substance, to act as a narcotic, must be able to enter the cells. Overton found that water can enter and leave cells quickly, and that of the organic substances, those penetrate the cells most quickly which, besides being soluble in water, are easily soluble in fats, such as the various fatty oils and certain allied substances like cholesterin, lecithin and protagon. Since the latter substances are known to occur very generally in animal and vegetable cells, it occurred to Overton that it is their presence in the cell which in large part determines the behavior of the cell as regards the reception into it of substances dissolved in the solution bathing it. If this were true, then the distribution of the substance in solution between the lymph on the one hand and the cell on the other will depend on the relation of its solubility in the water of the lymph to that in the fat-like substances in the cell. If the solubility of the substance in the cell fats or so-called "lipoids," be great, it will accumulate there and alter the function of the cell; if it be insoluble in the cell fats but easily soluble in water, it will not easily enter the cell.

An examination of narcotics showed that they could be divided into two great groups, (a) those that are chemically neither acids nor bases, but so-called "indifferent" substances, and (b) basic substances. To the first group, according to Overton's estimate, about one-half of all organic substances belong; the group also includes carbon dioxid, carbon bisulphid and nitrous oxid. When the concentration of the solution of a member of the group sufficient to cause narcosis of a given group of cells has been established, it is found that the same concentration of solution will generally exercise a similar narcotic effect on cell groups of the most various kinds. Further, the narcosis is temporary; when cells are removed from the narcotizing solution and placed in normal lymph or salt solution the narcotic effects quickly disappear and the normal function is restored; only when the concentration has been too great or the action too prolonged is the cell permanently injured.

To the second group of narcotics belong the organic bases and those salt-like compounds of them which on aqueous solution undergo hydrolytic cleavage, with reformation of the base. Ammonia belongs here also, but not solutions of sodium or potassium hydroxid. The nature of the cell membrane, its holding in lipoid substances, determines apparently its impermeability to dissolved electrolytes on the one hand and its easy permeability by substances soluble in fat on the other. The action of the organic bases of this second group of narcotics is wholly different from that of the substances of the first group in that the concentrations effectively narcotic for one group of cells may be totally ineffective for a cell group of a different kind, the concentrations necessary varying in some instances in the proportions of 1 to 10. Further, the action is not temporary, but prolonged, even when the cells are placed again in normal lymph or salt solution. And again, the narcotic effect does not take place so quickly after the penetration of the substance into the cell; it appears more slowly and tends to be progressive in its intensity. The conclusion is drawn that the basic narcotics in all probability form tolerably firm chemical compounds inside the cells with certain of the cell constituents. Though they can penetrate the cells tolerably quickly on account of their solubility in lipoids, they are not easy to remove from the cells, once inside. This, perhaps, explains how it is that so small a quantity as 1/3 of a milligram (1/200 grain) of curarin per kilo of rabbit, as Böhm showed, will suffice by its accumulation in the motor end plates to totally paralyze the skeletal muscles of the body.

The action of the so-called indifferent narcotics appears, on the other hand, to be physical rather than chemical. This view is supported by their lack of specificity of effect, by the relative chemical inertness of most of the narcotics concerned and by the speedy recovery of the cell when its normal environment is restored. The richer a cell variety is in contained fats, the more narcotic it will take up. This explains, perhaps, the affinity of such narcotics for nervous tissues, especially for medullated nerve fibers.

The opportunities for the application of the doctrine to the practical experience of the physician are obvious. One recalls at once the relatively large amount of chloroform or ether an obese patient may require before narcosis is established; with great masses of adipose tissue in the skin and omentum, each fat cell dissolving out of the lymph its store of the circulating anesthetic, a much larger amount of the substance may have to be administered before the effectively narcotic concentration in the lipoids of the nerve cells is attained, than would be necessary in an emaciated patient, where, as is well known, the nerve cells are among the last to yield up their store of fat. It must ever be kept in mind that solubility in fat is not the only factor concerned in connection with the behavior of the indifferent narcotics; just as important is the coefficient of distribution of the substance between lipoid and water. If this coefficient, lipoid water, is great, then the narcotic will penetrate the cell quickly; if it is small, only slowly. The remarkable results of Overton's studies thus far make us look forward with eagerness to his further publications. He is now engaged on a study of the phenomena of imbibition, and we may, therefore, expect before long to have new light thrown on this process, so obscure and yet so important for the function of cells.

Another investigator in v. Frey's laboratory whose results merit close attention is Gurber. His studies of crystallized serum albumin from the horse have assumed especial interest now that chemists as well as physiologists are beginning to concentrate their minds on the problems connected with the nature of the proteid substances.

A new text-book of physiology by Professor v. Frey has just been published.[1] I am wondering if it might not be a good rule for every medical man, no matter what his special branch of work may be, to read carefully every few years the newest and best text-books of physiology as they come out. Physiology stands closer, perhaps, than any other of the so-called fundamental sciences to the practicing physician, to whom its relation is that of anatomy to the surgeon. How many medical men greeted with delight and read with instruction Howell's American Text-Book, Stewart's Physiology, Loeb's Lectures and Schaefer's English Text-Book of Physiology, as they appeared! These books gave us renewed stimulus; in a connected fashion we were able to get a grasp of the progress science had made since our student days. We went back to our daily work with clearer ideas, with a new insight into the processes which go on in those bodies we have to treat. A rational therapy of disturbed function is impossible when the normal activities are not understood; the more sharply the processes which go on in health are stamped on our minds, the less likely are we to go astray in combating disease. This new book of von Frey's can be warmly recommended as a guide for the better class of medical students; as a succinct, interesting epitome of the science as it stands to-day, it should be of the greatest service to the busy practitioner. I wish it could be translated into English.

In less than 400 pages von Frey has brought together the more salient features of modern vertebrate physiology. I say vertebrate physiology, for von Frey is a greater friend of the physiology of higher animals than of that of the protozoa. The two schools of physiologists appear to have difficulty in understanding and fully appreciating one another. But each school has its brilliant representatives, and we as medical men probably do best to neglect the strife of the schools and to assimilate to our own uses the contributions of each. Some day a higher, more philosophical physiology will unify the facts of the science. I have been reading von Frey's book in the train in those long, lazy intervals between stopping places, so characteristic of European railways. Typical of the book is the opening chapter, which deals at once with the application of the doctrines of the conservation of energy and of mass to the processes which go on in living beings. The student has his physiology presented directly as a continuation, with utilization, of his studies in chemistry, physics and anatomy. The dynamic conception of the body is impressed from the beginning. The modernity of the presentation is made obvious by the use of the cm., gr., sec. system of units; the systematic application of the dyne, the erg and the other members of this system of units to all scientific measurements is now a matter of duty; medicine has been too long blameworthy in this regard.

---

[1] Von Frey, [illegible] Vorlesungen über Physiologie, Berlin [illegible]), 1904, [illegible] 1-392.

The original research of von Frey on the circulatory apparatus would lead us to expect that the sections of the book dealing with the blood, the work of the heart and the movement of the blood and lymph will be particularly strong and a perusal of them shows that the expectation is not disappointed. The series of beautiful experiments which physiology owes to Ludwig and his pupils are here successively presented and the results of subsequent investigators are carefully epitomized. The newer studies on the heart muscle and on the action of the valves of the heart can not fail to interest every clinician. The graphic methods for recording the evidences of activity in the various parts of the heart have undergone marked improvement of late. Especially valuable in this connection are the experiments of Einthoven, who registers the heart sounds synchronously with the apex beat. A whole series of new facts and a valuable critique of the older observations have resulted. Still more interesting and probably capable of greater application clinically is the method of studying the activity of the living heart by measuring the electric currents which originate at each beat. The capillary electrometer is the instrument used and the registered curve is known as the electrokardiogram. Some of our better American physiologists now give instruction in the use of the instrument in their practical courses, and it may be hoped that before long it will be more extensively employed at the bedside, especially as a method of correction of the original curves obtained has been introduced which permits one to eliminate the differences between individual instruments.

The section on the study of the pulse is largely an epitome of von Frey's former book on the subject; the three pulse-measuring instruments — sphygmograph, tachograph and sphygmomanometer—for the more accurate valuation of the various characters of the beat, are carefully described; von Frey's own contributions here to the improvement of the instruments are of high worth. The chapter on the vascular tonus will be of especial interest to medical men, now that clinicians are becoming more and more convinced of the vast importance of the condition of the small vessels at the periphery in all cases of disturbance of the circulatory apparatus. The chapter on this subject has been written with great care; the most important facts in a huge literature are given in résumé, and well-selected bibliographic references point the student to original sources of information. The fifth part of von Frey's book, that dealing with respiration, includes an interesting account of the studies of Bohr, who has, as is well known, revolutionized physiologic ideas in that domain during the past few years. Bohr has studied more exactly than had been done before the mode of combination of the oxygen in the circulating blood, and he and his pupils have shown that a fixed relation between the amount of hemoglobin present and the combined oxygen does not exist. His experiments also indicate that the hemoglobin of the circulating blood is a substance, the capacity of which for taking up oxygen is variable within certain limits which are as yet not fully understood. His studies of the compound which carbon dioxid forms with hemoglobin, the so-called carbohemoglobin, have shown that its formation is independent of the simultaneous presence of oxygen, and leads to no alteration of color that can be recognized either by the naked eye or the spectroscope; in all probability, therefore, the carbon dioxid unites with a totally different part of the hemoglobin molecule than that with which the oxygen combines. No less important, perhaps, are the studies of Bohr and Henriques on "internal respiration," through which they have been able to bring forward new facts concerning the exchange of oxygen and carbon dioxid between the blood and the tissues, and especially concerning the exact localization of the combustion processes. The discussion of the significance of the so-called "respiratory quotient" will be welcomed by many, for the clinicians who busy themselves with the study of diseases in which metabolism is markedly disturbed tend more and more to help themselves by calling to their aid the apparatus of Zuntz, or, better, that of Jaquet. It would seem a pity that so many metabolism experiments have had to be carried on, especially in clinical work, in a one-sided way. The measuring of the gas exchange alone suffices no more than a determination of the intake and output of nitrogen alone; but the great practical difficulty of comprehensive metabolic studies and the limited number of adequately trained assistants for the work probably explains the slowness with which progress is made along these lines. It must be pleasing to Americans to realize that thus far the experiments of Atwater are the best that have been made.

The sections of the book dealing with the physiology of digestion, absorption and assimilation are excellent. They could have been written only by one who has followed closely and with understanding the vast number of original researches dealing with the histology of the digestive and absorptive organs, the nature and action of ferments, and the organic and physical chemistry of the decomposition and synthesis of the proteid and carbohydrate substances. The more peculiarly biologic experiments, too, have been fully valued; the researches of Pawlow in Russia and of Cannon in Boston are given due prominence. Knowledge is moving with automobile speed in these districts; it is hard for a scientist to keep pace with it even in a "runabout;" he who will be abreast of everything must, of necessity, ride a "big machine."

The seventh and eighth parts of the book deal with the urine, with metabolism in general and with the maintenance of the body temperature; the remainder of the volume is devoted to a discussion of the functions of the muscles and nerves. Where all is good, it seems invidious to select any part for especial praise; I must state, however, that nowhere else to my knowledge is a better description given in so small a space of the functions of the organs of general and special sense. The central nervous system is dismissed, on the other hand, with a relatively meager account, a behavior for which, however, we can scarcely blame a physiologist when we recall how much of what is ordinarily given on the brain in text-books of physiology is really not physiology but anatomy. An American is somewhat surprised also to find no chapter in the book on reproduction; in Germany this subject is left to the text-books on anatomy. I have written chiefly, as will be seen, of the merits of the book, which seem to me unusual; it is a book which must appeal to those whose wish it is to see medicine brought more and more into accord with the exact sciences. But the book is not devoid of faults; the account given of the white blood corpuscles is defective and should be improved in another edition; there is no discussion of the theory of katalysis in connection with the description of the activities of enzymes, an omission which many will find hard to forgive, especially since the theory as put forward by Ostwald stimulates to important experimental work; and there are misprints here and there which mar the book. I miss, too, any reference to the important experiments of Stoklasa on the relation between the process of "internal respiration" and that of alcoholic fermentation. But these faults are such as can be easily corrected; the book as a whole is excellent and worthy of repeated reading and careful abstracting.

It is interesting to look over the list of names of younger men cited in the book. The names of Germany's former physiologists form a galaxy, in which Brücke, DuBois Reymond, Helmholtz, Ludwig and Weber were among the most illustrious persons. Engelmann, Gad, Hering, Hermann, Hürthle, von Kries, Munk, Pflüger, Rosenthal and Voit are living, but can no longer be regarded as young men. Now we hear of Bethe, Bohr, O. Cohnheim, Cremer, Ewald, Einthoven, O. Franck, von Frey, Tucke, von Grützner, Gürber, Hofman, Kossel, Overton, Schulz, Siegfried, Steinbach and Verworn. Some of these are really not German; Bohr is a professor in Denmark; Einthoven is a professor in Holland; Overton is an Englishman working in Germany. Will the German physiologists of to-day rank with their predecessors, is a question which many are asking. The answer must be left to the future.

In Würzburg, von Leube is the professor of internal medicine. He is everywhere regarded as one of the best diagnosticians in Germany and his text-book on diagnosis has long been used and highly prized by American physicians who read German. I note that the last edition of this useful book has been translated into English by Dr. Salinger; it is certainly matter for congratulation that its contents have now been made generally accessible to English and American readers.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Pneumonia.

The specific organism which is the cause of pneumonia, the *Micrococcus lanceolatus*, can be found in any part of the respiratory passages in normal individuals. In pathologic conditions it finds its way into the blood of patients and in this way gives rise to various complications. Unless the pneumococci, therefore, are found in the sputum in pure culture their presence is of no diagnostic value. In many cases of lobar pneumonia other organisms are present, such as the streptococcus and Eberth's bacillus. The bacillus of influenza may be the etiologic factor in pneumonia; alone it never causes a true lobar pneumonia, but a lobular pneumonia which may be confined to one lobe as shown on autopsy.

PROPHYLAXIS.

The treatment of pneumonia may be divided into the prophylactic treatment and the treatment of the attack. The prophylaxis as recommended in the bulletin of the Department of Health, Chicago, consists in:

1. Destruction of the sputa.
2. Prevention of soiling the patient's surroundings and thorough disinfection of the room afterward.
3. Thorough ventilation.

GENERAL TREATMENT.

H. P. Loomis, in the Practical Medicine Series of Year Books, gives an account of the following general line of treatment of pneumonia in four of the leading hospitals of New York:

Calomel is first given in small doses, often repeated, followed by a saline in the morning. This is repeated during the course of the disease if necessary.

Flaxseed poultices are applied as local measures. In some cases the pneumonia jacket is used. The treatment of the fever varies. In some cases the tub bath is used at a temperature of 103 F. and over, when the patients are alcoholics or are delirious, and they are sponged regularly when the temperature is 102 F. For the very severe pain poultices are applied or a hypodermic injection of morphin is given if necessary.

For the insomnia, codein, trional or bromids are employed, and for cardiac weakness alcohol, strychnia and digitalis. Alcohol is administered in doses of one dram (4.00) at intervals of from one to four hours, according to indications.

Strychnia is used for two indications: 1. As a heart stimulant secondary to whisky. 2. Where there is evidence of pulmonary edema and cyanosis. It is given hypodermically in doses of grain 1/20 (.003) each. Digitalis is given in cases that do not respond to whisky and strychnia.

Although statistics have been gathered from various sources to prove the value of this or that drug as a specific in pneumonia the fact must not be lost sight of that pneumonia is a self-limited disease, and terminates suddenly in recovery. The reasoning, therefore, is not good that such results are due to certain specific lines of treatment, as statistics may show. But there are a few preparations which have proved so universally of value in the hands of competent observers that they are worthy of mention, among these may be mentioned quinin, creosote carbonate, digitalis, calomel and alcohol.

Rochester, in *Med. News*, Feb. 13, 1904, states that the present antitoxic sera are of no value in the treatment of pneumonia, and until a reliable antitoxin is obtained the treatment must continue along the lines of elimination and support of the patient. Large amounts of pure water should be given to increase the elimination. The eliminative action of the liver and bowels must be kept up through the vigorous use of calomel and salts. The skin must promote elimination through sweats induced by external heat. If indicated, the work on the right heart may be lessened by blood-letting. Stimulation to the heart may be obtained by administering strychnin, alcohol, ammonium carbonate, and, in suitable cases, the subcutaneous injection of the normal saline solution and local treatment applied by leeching and dry or wet cupping.

Sweating may be induced by the hot mustard footbath given in bed without any disturbance to the patient. The patient, in a nude condition, lies between blankets with his knees flexed, his feet in the tub which has been placed under the blanket, the long axis being in the line of the patient's body and legs; another blanket passes from under the tub up over the end and over the knees of the patient. From two to five blankets or a fewer number of blankets and a rubber sheet are then placed over the patient, extending from head to foot and tucked around the patient. The tub is at first filled half full of hot water, in which a heaping tablespoonful of mustard has been dissolved and hot water added as indicated. The bath is kept up for from thirty to forty-five minutes, according to the amount of sweating produced.

During the bath, cold cloths wrung out of ice water are kept constantly on the head of the patient.

The mouth should frequently be thoroughly cleansed with an antiseptic solution. In wet cupping, the author recommends that the cups be left on for half an hour and the process repeated every four or six hours. He relates the value of this procedure by anatomic conditions observed postmortem. He is not enthusiastic over the applications of ice locally.

The dangers of tympanites in pneumonia are regarded by some authors as being of as great a danger as its presence in typhoid fever, both in a mechanical way through pressure upward and embarrassment of the respirations and through the increased tendency to absorption of toxins. Therefore, the same treatment of this complication should be carried out as in typhoid by change of diet, irrigation of the bowel, salol and laxatives and local application of turpentine stupes.

The embarrassment shown by the lungs in any infection producing tympanites may be demonstrated on autopsy. Oestreich has shown that the atelectatic condition of the base of the lungs in young infants dying from acute intestinal troubles is the probable cause of the extreme prostration and death in these cases rather than the toxemia which is so frequently looked on as the cause.

The rules laid down by Lees for the use of the ice bag in pneumonia, as quoted in the *Sys. of Physiologic Ther.*, are as follows:

1. Apply the ice bag over the dull area and especially over the advancing edge of the consolidation.
2. If the area is large, use two ice bags, or even three.
3. Expect to find a distinct local effect (less bronchial breath-

ing and looser râles) on careful physical examination after the ice has been applied for twenty-four hours.

4. If fresh areas of consolidation develop use additional ice bags; four or even more may be used in a bad case. Correct dosage is as important as with drugs.

5. Apply hot water bottles to the feet and legs. In children apply these before applying the ice.

6. Examine the signs twice daily and shift the ice bags accordingly.

7. If pericarditis is present as a complication, place an ice bag over the heart.

8. If the temperature is below 99 F. or if the hands are cold or the lips blue, remove the bags for an hour, then replace them and use them for two or three-hour periods, with one or two-hour intervals.

9. In severe cases with cyanosis and with a rapid, feeble pulse, consider whether leeches would not relieve the right heart.

10. Pneumonia treated with ice within twenty-four hours after the rigor may sometimes be aborted.

In considering the efficacy of any treatment of pneumonia, Preble, in his recent work on "Pneumonia," states that the variations in the degree of malignancy in the different years must be taken into account; also the previous condition of the patient. Alcoholics, as a rule, are overworked and underfed. In any case, empiricism is not likely to succeed in the treatment of this disease. From a theoretical standpoint, the ideal treatment would be: 1. To destroy the infective agent; 2, to neutralize the toxic products. In this connection he states that no certain progress in the experiments with sera has been made. While some have claimed good results and success from such treatment, others have failed, and consequently any opinion concerning the benefits derived from their use must be held in reserve. He mentions the experience of others in the use of quinin, administered in the form of the tannate, and especially the hypodermic administration of the hydrochlorid in one-half gram doses, administered to patients who are delirous with a small, soft and rapid pulse. And while there is as yet no specific for pneumonia, as this author states, it does not mean that the physician must sit idly by; but, on the other hand, active, thoughtful, careful attention must be given to the patient, who should be placed in a large airy room, with a free circulation of air through one, or better, through two windows. The number of attendants should be limited to one or two. The temperature of the room should be held at 65 F. or less. The patient should be placed on a single bed, with firm springs and mattress. The clothing should be light, proportionate to the temperature of the room. The cotton jacket is of no benefit. The diet should be properly regulated and water offered the patient frequently.

No alcoholics are recommended except in extreme cases and in alcoholic patients. A proper amount of sleep must be obtained, and, if necessary, trional, chloral or whisky may be administered if absolutely necessary.

Fever.—The fever, when ranging under 105 F. in the young or 103 F. in the old, rarely requires more than the ordinary sponging or bath at 90 F. gradually cooled to 80 or 75.

Pain.—Pain can usually be controlled by the application of cold to the parts or counter-irritation by means of iodin, mustard, leeches, or cupping. If these measures fail, strapping the chest is recommended, as in case of a broken rib, using tape from one-half to one inch wide, and placing the lowest strip at the twelfth rib; each succeeding strip should lap over the one below. These should be carried up until the shoulder-chest muscles are reached, then strips should be carried from before backward over the shoulder.

As a last resort to stop the pain morphin may be given hypodermically in doses of grain ⅛ (.008) each.

Cough.—The cough should be treated only when persistent and when the patient is deprived of his rest. In such cases and when the patient is deprived of his rest. In such cases give morphin. The stimulating cough mixtures should never be given early and not until after resolution has commenced. Even in that stage Dr. Preble recommends in their stead guaiacol carbonate in five-grain doses (.30) three or four times a day, or combined with apomorphin, gr. 1/20 (.003).

Dyspnea.—Dyspnea, if it occurs before the second stage is reached, is best treated by venesection. If the patient is not too weak or anemic 18 to 20 ounces may be withdrawn with splendid results. The benefit of oxygen administration is very doubtful, and when it is given the cone should not be held too tightly against the patient's mouth, but some distance away.

Cardiac Failure.—Cardiac failure is the cause of death of the patient. The treatment for this condition consists in the local application of the ice bag, the administration of digitalis in the form of the infusion or fat-free tincture. The alkaloid digitalin has given negative results in Dr. Preble's hands, but he recommends digitoxin as a very valuable heart stimulant. He is of the opinion that the usually prescribed dose of grain 1/250 (.00025) is too large, and he has derived better results from the administration of grain 1/500, and even then the heart must be watched while under its influence.

In old heart lesions, digitalis and nitroglycerin are the ordinary preparations relied on. Cold baths, as a rule, will govern the nervous symptoms. In alcoholics, daily doses of chloral, grains 60 (4.00) may be given.

Small doses of morphin are of benefit in relieving the insomnia, but should be used with caution.

Delayed Resolution.—Delayed resolution requires a climate where the patient can get out every day along with the employment of the iodids, massage of the chest muscles and the practicing of breathing exercises.

DIET IN PNEUMONIA.

In pneumonia the diet is of the greatest importance. That form of diet should be prescribed which will not increase the cough in swallowing, and will not disturb the stomach and thus aggravate the dyspnea. During the height of the disease the patient should be kept on a liquid diet composed of milk, whey, meat juice, broths and egg albumin. The amount of starchy and saccharine foods should be limited. An abundance of water should be given either plain or carbonated, in order to increase the activity of the kidneys and promote toxin elimination. It is stated by some authorities that carbonated waters reduce the viscidity of the sputum, which, as a rule, is very tenacious in pneumonia.

The liquid diet should be continued until after resolution has commenced unless resolution is postponed, as sometimes happens, and if the patient shows failing strength other food may be added in the way of milk toast, scraped beef, and soft-boiled egg or eggnog. In some cases predigested foods must be substituted when the milk is not well borne.

Fruit may be allowed during the course of the disease, depending on the individual case, and especially is it of benefit during convalescence. Orange juice, lemonade and grape juice are of value during the severest stages. In children even more care must be given to diet, as the appetite is very variable and many resources must be at hand to meet their desires and needs.

Dyspnea in Bronchial Asthma.

Dr. W. F. Wagner, Washington, D. C., writes to The Journal concerning the use of suprarenalin solution for the relief of the distressing paroxysms of dyspnea in bronchial asthma. He administers, hypodermically, from two to ten drops of the solution diluted in from ten to twenty drops of normal salt solution or sterile water. He states that in a few minutes the distressing shortness of breath is relieved and the patient is able to breathe in a perfectly normal manner. Dr. Wagner finds that when given by the mouth the same results are not experienced. One injection may give complete relief or it may be necessary to repeat the dose in from eight to twenty-four hours. This treatment relieves the paroxysm, but no curative effect has been observed.

[To guard against accident, it would be well to commence with a small dose, as some patients are more susceptible to the drug than others.—Ed.]

Medicolegal.

Sale of Liquor by Physician to One with Sickness in Family.—The Supreme Court of Arkansas says, in Blakeley vs. State, where it confirms a conviction of a practicing physician of selling whiskey without a license, that the statute of the state forbids the sale of whiskey without a license and makes no exception, but under certain conditions it permits regular practicing physicians to prescribe and to furnish such stimulants to patients under their charge in prohibited districts when deemed necessary for their treatment. If it be admitted that the sale of whisky by a physician for the purposes named, and after he has complied with the conditions of the statute as to the filing of his affidavit, would not be unlawful, still the statute clearly does not authorize the sale of whisky to a man simply because some member of his family was sick.

Liability for Malpractice. X-Ray Evidence.—The Supreme Court of Arkansas says that, in the malpractice case of Miller vs. Minturn, brought by the latter party, the injury was diagnosed as "a compound dislocation of the tibia at the ankle joint, complicated with a Potts fracture." The evidence on the part of the plaintiff fully sustained the charge of malpractice. That on part of the plaintiff approved his treatment, and exonerated him from negligence and unskillfulness. The jury settled the conflict in favor of the plaintiff. It was then insisted that the verdict for $1,500 was excessive. Mrs. Minturn suffered great pain for many months. At the time of the trial she was still unable to bear any weight on the injured limb, and the indications were strong that it would be years, if ever, before she regained use of her ankle. It was suppurating for many months after the physician treated it, and it was apparent that the bones were not properly brought together. The jury was convinced, from legally sufficient evidence, that this unfortunate condition was directly due to the unskillful and negligent treatment of the physician. The verdict was not excessive. Nor does the court consider that the physician could claim the exemption allowed by the constitution of Arkansas against execution on a judgment "on debt by contract," the action, in substance, being for the wrongful act (tort) of the physician. It says that the action could have been brought for breach of contract or for the tort (wrongful act)—in the former case relying wholly on the contract, express or implied, to treat skillfully and carefully, and waiving the tort, or, in the latter, the contract could be ignored, or pleaded as an inducement, and the action sound in tort alone. Again, the court says that the objection was made to the introduction of *x*-ray photographs of the injured ankle, on account of the alleged inherent weakness of such evidence, and lack of expert knowledge of those making them. The photographs were taken by a professor of the university, with an apparatus belonging to the university, and one of the best made. One of the plates was developed by the professor, and the other by an experienced photographer. The professor's knowledge of radiography was acquired from reading and experimentation. He was frank in admitting this was a subject not thoroughly understood by him, nor any one else. Counsel quoted medical authority to the effect that "radiography, though useful, is at times dangerous, by misleading: by no means to be assumed infallible by a jury or a court." Giving full sweep to this caution in regard to this new science, it did not prove the photographs inadmissible, but merely that they were not infallible and might be misleading. The frankness of the witness was a sufficient guard against their being treated as infallible, and there was nothing to indicate wherein they were misleading. There was no error in admitting them in evidence.

Malpractice Liability of Christian Scientist.—The Supreme Court of New Hampshire, speaking through Bingham, J., says that what the parties mutually expected, in the malpractice case of Spead vs. Tomlinson, was that the defendant would treat the plaintiff for appendicitis according to Christian Science methods; and it necessarily followed that the defendant, in the treatment of the plaintiff was to be judged by the standard of care, skill and knowledge of the ordinary Christian Scientist, in so far as he confined himself to those methods. Had the plaintiff been an infant, non compos, or had never assented to Christian Science treatment, then the question whether the practice of Christian Science, as applied to the treatment of appendicitis, is so contrary to common sense and reason that it would be negligent for such a practitioner to undertake to treat the disease, might be open to consideration by a jury. But being a person of mature years, and having sought such treatment, she could not complain that the method itself was improper. After the filing of the opinion by Bingham, J., on the request of the parties, they were further heard by brief and oral argument, and Young, J., prepared an additional opinion for the court, in which the conclusion is reaffirmed that plaintiff's intelligent and voluntary consent to follow the defendant's advice and to abide the result of his prayers was an answer, under the circumstances, to her claim for damages on account of negligence. It is said that nothing is opposed to public policy which is not forbidden by some provision of law, the contention that it would be contrary to sound public policy to permit the defendant to escape without paying damages must mean that there was some provision of the constitution or statute of the state, or of the common law, which made it illegal for the defendant to rely solely on prayer to heal the plaintiff when he knew she had chronic appendicitis, and which gave her an action to recover all the damages she sustained because of such reliance. The courts were not authorized to allow an action against the defendant, even if they thought he ought to have known that Christian Science must fail when applied to the treatment of chronic appendicitis, unless there was a general rule of law which gave such an action. If the plaintiff was to recover on the ground of public policy, she must establish (1) that it was illegal for the defendant to give her such treatment; (2) that the duty of not giving it was imposed on him for her benefit; and (3) that no illegal act of hers contributed to cause her injuries. Assuming (without deciding) that such treatment is forbidden by the provisions of section 8, chapter 278 of the Public Statutes of New Hampshire of 1891, which makes the killing of a human being by culpable negligence manslaughter, or by the provision of the common law which makes it unlawful for any one to do what is liable to endanger the life or health of others, and that the duty of not doing what is forbidden by either provision was imposed on the defendant for the plaintiff's benefit, the question still remained whether the plaintiff's own wrong contributed to cause her injuries. It is elementary that, if it was illegal for the defendant to treat the plaintiff as he did, it was equally illegal for her either knowingly to employ him to give her such treatment or to consent to be *so treated*. It did not follow, as a matter of law, from the fact that the plaintiff could not recover in this action on the claim of negligence, that the defendant would not have been guilty of manslaughter if the plaintiff had died from the effects of his treatment. If he had been indicted under the provisions of Sec. 8, C. 278, Pub. St. 1891, the state would base its right of action on his failure to perform a duty the law imposed on him for its benefit. The state has a direct interest in the lives and health of all its citizens. Every one who has to do with the lives and health of others not only owes the individuals with whom he comes in contact a legal duty, but also owes the state the duty of using ordinary care to do nothing which will endanger their lives or health. In an action by the state it would be no answer to show that, if the deceased had used ordinary care to avoid being injured, he would not have died; for the defendant is not indicted for his failure to perform a duty the law imposed on him for the deceased's benefit, but for his failure to perform one imposed on him for the benefit of the state. Assuming that the defendant's statement that he could and would cure the plaintiff might be the foundation of an action of deceit, her case failed, for there was no evidence that he made it with a fraudulent intent. Although a jury could find from their knowledge of human affairs, their own experience, and the evidence in the case, that the defendant's statement that he could cure the plaintiff without the aid of any material agency, when he knew she had appendicitis, was untrue, it did not follow that they could infer, from the single fact that they were convinced of its untruth, that the defendant did not believe he could induce God to heal her when he made the statement. The plaintiff failed because of the insufficiency of her evidence to prove the facts necessary to maintain her case.

3 *Theory and Practice of Percentage Feeding in Infancy. W. P. Northrup, New York City.
4 *Lobar Pneumonia in Infancy. J. L. Morse, Boston.
5 *Foreign Bodies in the Esophagus. C. E. Black, Jacksonville, Ill.
6 Strabismus and Its Treatment. C. M. Harris, Philadelphia.

3. **Percentage Feeding in Infancy.**—Northrup discusses the question of infant feeding, especially with modified cow's milk. For those turning their attention for the first time to the subject, he offers the following guiding points to serve as a basis in the feeding of healthy infants: 1. *Sugar solution.*—For the first three to five days of life a normal infant may take a 5 per cent. watery solution of sugar of milk, 3 to 4 drams, every three hours. From the fifth to the seventh day, the infant may be given fats, 2 per cent.; sugar, 5 per cent.; total proteids, 0.5 per cent., or whey proteids, 0.25 per cent.; caseinogen, 0.25 per cent.; feedings, 10; amount in each feeding, 1 ounce; alkalinity, 5 per cent. Heated to 155 F. for twenty minutes, or raw, if preferred. Feed every two hours by day, twice at night. 2. *Low average breast milk.*—From the first fortnight to the first month, according to its ability to digest, the average infant may take this, which consists of fats, 3 per cent.; sugar, 6 per cent.; whey proteids, 0.5 per cent.; caseinogen, 0.25 per cent; feedings, 10; amount in each feeding, 1½ to 2 ounces; alkalinity, 5 per cent. Heated to 155 F. for twenty minutes, or raw. Feed every two hours. 3. *High average breast milk.*—For the second or third month this may be taken. It consists of fats, 4 per cent.; sugar, 7 per cent.: total proteids, 1 to 2 per cent., or whey proteids, 0.9 per cent.; caseinogen, 0.5 per cent.; feedings, 8; amount in each feeding, 3 to 4 ounces; alkalinity, 5 per cent. Take raw, if weather is not too warm. Intervals of feeding, 2½ hours. At 6 months, 6 feedings, 6 ounces; intervals, 3 hours; total in 24 hours, 36 ounces. Against constipation, give raw, unboiled proteids. Never consign a baby to a definite prescription, especially a weak one, and then forget it for months. Develop the feedings to the maximum (a good, full diet), especially the proteids, and give raw. Proteids can be given in clean, laboratory-modified milk to a higher percentage than earlier teachings lead us to believe. The feedings of an infant under a year old should be inspected every two weeks.

4. **Lobar Pneumonia in Infancy.**—Morse believes that the course and prognosis of this disease differ materially from the descriptions given in many text-books, and that the affection is far more common than is generally supposed. The clinical history and treatment of the condition are discussed in full.

5. **Foreign Bodies in the Esophagus.**—Black reports two cases of this kind and comments on the value of the Roentgen ray in arriving at a correct diagnosis, disclosing the nature and location of the body in the esophagus. He also emphasizes the value of fluoroscopy, not only as an aid to diagnosis but in directing and controlling the handling of instruments in the esophagus. One of his patients had swallowed an ordinary pin and the other a half-inch iron washer. The pin was removed with forceps under the guidance of the fluoroscope, but the washer could not be budged, owing to the extremely swollen tissues. This second patient expired suddenly, after vomiting a dark fluid consisting of partly digested blood and stomach fluids.

12 Geheimrath Dr. Dettweiler. Eulogy Pronounced on the Occasion of the first Anniversary of His Death. S. A. Knopf, New York City.

7. **Bubonic Plague.**—White describes in full the biology of the plague bacillus and its pathogenesis; the pathologic characters of the clinical varieties of plague, the bubonic, the pneumonic, and the septicemic; the postmortem appearances of the plague rat, insects, and other animals; the clinical and bacteriologic diagnosis of plague; the hosts and distributors of the infection, and the manner of its transmission from one place to another. As the principal transmitters of infection from port to port he recognizes: 1. Imports likely to be eaten or infested by insects and rats; 2. persons, wearing apparel and bedding; 3. scavenger and, possibly, granary insects; 4, rats and other animals.

8. **Limitations of Office Treatment. of Rectal Diseases.**—Kelsey says that a very large proportion of all cases of piles, fissures, superficial ulcers, and pruritus, and a certain proportion of abscesses and fistulæ may be radically cured in one's office without resorting to the use of ether or confinement to bed, but much judgment is necessary in selecting the proper cases. In general, it may be said that it is often simpler in the end and safer and more comfortable for the patient to operate at home or in the hospital.

9. **Use and Abuse of Curettage.**—Browd pleads for a more careful, discrete and scientific application of curettage; discusses the method of performance, its indications and contraindications, and cites several cases in which a disregard of necessary precautions resulted in serious consequences.

10. **Gluttony as Cause of Symptomatic Epilepsy.**—Spratling cites a case of epileptic convulsions due to dietetic errors, a fairly common condition, and one generally amenable to treatment. The patients are usually middle-aged men, leading inactive lives and eating and drinking to excess. The primary cause of the convulsive attacks in these cases seems to lie, first, in a weak stomach and, second, in some obscure disorder of metabolism. The type of convulsion is usually of the grand mal variety. The treatment consists of the elimination of waste and toxic products and the prevention of the recurrence of such products. Put the patient on a low diet, one that is easily digested, insist on absolute regularity in taking food, and going to bed on an empty stomach. Cut off all meat for supper and breakfast, and teach the patient to have a wholesome respect for cooked fruits, bread and butter, toast, milk, chocolate and cocoa, eggs, and other such things for supper. If there is a *tendency* to constipation correct it by daily doses of the fluid extract of cascara given some time before breakfast. Stop all use of alcohol and if the patient is irritable or nervous, and if his attacks show a tendency to recur under the low dietetic régime put him on a nerve sedative made up so that each dose represents from 10 to 15 grains of an equivalent of bromide of potassium. Let the patient *take* as much outdoor life as possible. Hydrotherapy is of great value.

19 Radiograph and Hip Disease.—Lovett and Brown undertook to determine what value radiographs possessed, taken by themselves, in the diagnosis of hip disease, and especially in the detection of early disease One hundred consecutive negatives of the hip joint were examined. The clinical history of each case was looked up later and the value of the opinion formed from the radiograph tested in this way These cases included practically every obscure and difficult case of trouble in the hips seen during the last three or four years at the hospital in which these investigations were made, for such cases were likely to be *x*-rayed, whereas routine cases might not be The 100 cases classed by the opinions expressed from examination of radiographs may be tabulated as follows Normal, 20 cases, hip disease or probable hip disease, 61, old hip disease, 4, destructive disease, not tuberculous, 2, coxa vara, 2, doubtful or questionable, 4, abnormal, but not hip disease, 2, probable hip disease (proving to be abscesses of groin), 2, various diagnoses not borne out by clinical history, 3 Of the normal cases, 8 were radiographed for other affections, such as Pott s disease or stone in the bladder, and the hips were included incidentally. Seven cases were radiographed for suspected disease, but recovered so speedily that the affection was probably synovial Two cases with a normal radiograph showed a typical history of hip disease Three cases pursued a history not characteristic of hip disease Therefore, the fact that the radiograph is normal is of much significance and should make one delay about diagnosticating hip disease in such cases Of the 61 cases diagnosticated as hip disease from the radiograph, the clinical history was typical, and the subsequent course of the affection confirmed the radiographic diagnosis The radiographic diagnosis of old hip disease was borne out by the clinical history That of destructive disease not tuberculous proved to be osteomyelitis of both hips in one case, and in the other a hip following typhoid The diagnosis of coxa vara was substantiated by the clinical diagnosis In the two cases diagnosed as probable hip disease, the clinical records showed that these cases had suffered from an acute abscess of the groin in no way connected with the hip. The clinical history of the four questionable cases showed that in one there was atrophy, in another slight atrophy with some enlargement of the head and neck, in the third there was thickening of the head and neck and dislocation; in the fourth, slight atrophy with thickening of the head. The two cases classified *as abnormal* but not hip disease were found to be suffering from some acute affection of the hip, from which they recovered in a few weeks. In the remaining three cases the *x*-ray appearances did not agree with the clinical history. In two what appeared to be marked signs in the hip went with the history of a slight affection, and in the third an opinion was expressed that a destructive affection was osteomyelitis, while bacteriologically it proved to be tuberculous The authors conclude that the value of the radiograph in the diagnosis of hip disease is great in the *hands of persons of average experience.* That a radiograph free from abnormal appearances does not show that hip disease is absent or will not develop, but that in a case of doubtful clinical diagnosis a normal *x*-ray is a matter of weight and makes the likelihood of speedy recovery greater than will a radiograph with abnormal appearances 'In 95 of these cases the opinion formed from the *x*-ray was borne out clinically.

25 New Stain for Tubercle Bacillus.—Wile's *method* is as *follows:* The film is prepared and stained with carbolfuchsin in the usual way, but, instead of using Gabbet's solution, or decolorizing with acid alcohol and counterstaining with Bismarck brown, the smear is drained of excess of carbolfuchsin stain, washed in distilled water, and then plunged repeatedly into Labarraque's solution until the slide presents a uniform brown appearance. The slide is thoroughly washed in distilled water to remove an excess of hypochlorite solution, dried between blotting or filter papers, and examined with a 1/12 immersion lens The tubercle bacilli appear as red rods on a brown field Other bacterial forms, with the possible exception of the smegma and lepra bacilli, are brown in color—the red having been altered to brown by the action of Lebarraque's solution

32 Points Pertaining to the Management of Diabetic and Non diabetic Glycosuria (Concluded) H Stern, New York City

29 Gastroenterostomy —Mumford proposes an operation he has practiced of late in cases of gastric cancer, which returns the parts to an essentially normal anatomic condition The operation is an elaboration of the well known procedure of Chabut Mumford adds a fourth step to the operation, that of invariable, routine section of the pylorus. He says that it adds nothing to the risk, the vicious circle is rendered impossible, and the duodenum, being side-tracked, becomes a mere duct, a continuation of the common bile duct

31. Etiology of Tuberculosis in Relation to Therapeutics.—High urges going beyond the findings of the microscope, and considers as a reason for the universal prevalence of the disease the incalculable extent of physical degeneration of median degree due to the simple lack of clean, pure, unbreathed outdoor air, on account of which tuberculosis finds a foothold. Treatment should be directed that way, in addition to efforts made to destroy the tubercle germ

38. **Pseudobulbar Palsy.**—Weisenburg reports the following cases: 1. Man, aged 56, syphilitic. History of several attacks of hemiplegia involving the left side of the body, but no distinct history of a right hemiplegia, although the patient had subsequently slight attacks, and examination showed a weakness of all the extremities, distinctly more marked, however, on the left side. The reflexes were also more exaggerated on the left side. Sensation was normal. Speech was bulbar in character; there was difficulty in swallowing and eating; dribbling of saliva, forced crying and dementia. Microscopically, on the right side, an area of secondary degeneration was found in the middle part of the posterior limb of the internal capsule, and a sclerotic area in the outer portion of the lenticular nucleus. The middle part of the foot of the right cerebral peduncle was degenerated. Degeneration of motor fibers was traced through the pons and medulla into the lumbar region of the cord. In the cervical and thoracic regions the degeneration of the right direct pyramidal tract was more intense than that of the left crossed pyramidal tract. On the left side of the brain an area of softening was found in the knee of the internal capsule. The innermost part of the foot of the left cerebral peduncle was degenerated. The degeneration in the pons was limited to one or two bundles quite near the raphe and in the ventral part of the pons. In the medulla oblongata it was confined to the outer part of the pyramidal tract. In the cervical and in the mid-thoracic regions the degeneration was confined to the direct pyramidal tract. The nuclei and the intramedullary fibers of the different cranial nerves were normal. The optic and oculo-motor nerves were normal. The tongue and the laryngeal muscles were normal. Syphilitic round-celled infiltration of the pia was apparent in the cord and brain. 2. Man, aged 52 years, not syphilitic, had a number of attacks of hemiplegia, involving first the left side and later the right. Difficulty in speech and in swallowing became apparent after the second attack. All the extremities were weak, especially those on the left side. Sensation was normal. The patient was demented, had bulbar speech, difficulty in swallowing and chewing, and dribbling of saliva. An area of softening was found in the knee of the right internal capsule. *Microscopically, an area* of softening was found in the medulla, confined to the left pyramid, and a small part of the adjacent fibers of the left lemniscus. Other areas of softening were found in the knee and in the anterior part of the posterior limb of the left internal capsule, and in the ventral part of the red nucleus on the same side. Secondary degeneration of the pyramidal fibers was traced on both sides to the lumbar region of the spinal cord. 3. Man, aged 55 years, not syphilitic had several attacks of hemiplegia, confined to the left side. Examination showed a weakness of all the extremities, more so, however, on the left side. There was difficulty in speech, in chewing and in swallowing. Saliva dribbled from the mouth. The mentality was poor. Areas of softening were found on the right side of the brain, in the anterior limb of the internal capsule near the knee, and in the outer part of the lenticular nucleus, also involving the fibers passing to the posterior limb of the internal capsule. On the left side there was a scar of an old area of softening in the substantia nigra of the left cerebral peduncle. The median and adjacent part of the foot of the right cerebral peduncle was degenerated. The secondary degeneration of the motor fibers was traced to the crossed pyramidal tract of the cervical region of the spinal cord.

46. **Use of Modified Champetier de Ribes Balloon.**—Voorhees says that of the many measures in use for starting labor and for shortening its duration none is of more value in certain cases than the use of a conical cervical dilator—Champetier de Ribes balloon. The operation for the insertion of the balloon is very simple, except in a few instances, and can be done with one assistant—the nurse. An anesthetic is employed only in those cases where a preliminary divulsion or a manual dilatation of the cervix is necessary to get enough room for the insertion of the bag, where the cervix is so high that it is difficult to reach when the patient is very nervous and excitable, or where the vulvar orifice is very narrow and sensitive. Here light chloroform narcosis is all that is required. The bags employed by Voorhees differ very little from those of Champetier. They are identically the same in shape and are made with his principles—to be impermeable, to be inextensible beyond a certain volume, to be long enough to fill the cervix—in short, to simulate nature's bag as nearly as practicable. Voorhees' balloons differ somewhat in size and are made stronger in order to withstand the uterine and abdominal contractions, to resist the tension when filled with a fluid, and to permit a certain amount of traction on the tube without rupture. This required a foundation of thin canvas, instead of silk, covered by a thicker rubber outside, but, more than all, that the seams be firmly sewed and cemented, especially where the tube joins the ampulla. Some of the objections to the balloons are: 1. They may rupture the membranes. This happens rarely, and it makes little difference if they do, says Voorhees. If the fluid does escape, the dilatation is rapid enough to do little harm. 2. They may separate the placenta—only in placenta previa, but the bag arrests the hemorrhage. 3. They may increase the tension in the interior of the uterus, which is neither painful nor harmful. 4. They may displace the presenting part, but by slow distention of the bag and by watching the presenting part, it can be kept in place. This is more apt to occur in cases of flat pelvis. 5. The cord may prolapse, if it is long or loosely coiled about the neck. 6. Sepsis. If the aseptic technic is correct there should be no infection. Voorhees is convinced that the modified balloon is the best artificial hydrostatic dilator of the cervix; that it is especially effective in dry labors to start pains; that labor, if prolonged and protracted from whatever cause, is hastened and in a large percentage of the cases terminates spontaneously after their use; that the balloon is the best and most certain method of inducing labor for all indications, and that in eclampsia and in placenta previa the balloon has a field of usefulness which

diminishes markedly maternal and fetal mortality. In his private practice Voorhees has used the balloon in 39 out of 200 cases. One of these 39 cases was a dry labor. All the children did well. The balloon was used in 4 out of 19 prolonged or protracted labors. Three were primiparæ with occipito-posterior positions, and in 1 the pelvis was a flat justa-minor. In all, the membranes had been ruptured for some hours. Oxytocics and chloral had been used without success after the patients had been in labor from 13 to 39 hours. The cervix was tough in all cases and undilated beyond two fingers at the time of introduction of the balloons. Complete dilatation was accomplished in from 5 to 32 hours. All the mothers and babies did well. In the 200 cases, labor was induced 32 times. A bougie was used in 8, but had to be supplemented by a balloon. In 24 cases the bag was employed alone. Ten were primiparæ, 19 were multiparæ. The indications for the induction of labor were contracted pelvis, chronic endocarditis, prolonged gestation, accidental hemorrhage, albuminuria and threatened eclampsia and a history of previous difficult deliveries and still-births. All the children were born alive except one, a craniotomy case. Two subsequently died—a non-viable child in a case of accidental hemorrhage, and one of a case of premature twins. The balloon was also successfully used in two cases of marginal placenta prævia. Statistics are also quoted in detail of 4,272 cases occurring at the Sloan Maternity Hospital during the four years ending Sept. 1, 1903, for which we must refer our readers to the original article.

48. See abstract in THE JOURNAL, vol. xvii, p. 487, ¶6.

49. **Suture and Ligature Material.**—Congdon has for several years employed catgut, which is modified so that it may be boiled like silk, and is, therefore, rendered thoroughly dependable for deep sutures and ligatures without destroying its ultimate absorbability or interfering with its natural adaptability for handling and tying. He takes dry catgut, which comes in strands ten feet long, carefully tests for imperfections by passing through the hands and noting its strength and inspecting it for weak points and irregularities, fastens one end to the end of a glass cylinder, for instance, an ordinary drainage tube which has a hole drilled near each end, winds snugly in a single layer, and fastens the other end similarly. Then completely submerges in a 3 per cent. formalin solution. No. 4 is allowed to remain in the solution for four hours, No. 3 for three hours and five minutes, No. 2 for two hours and fifteen minutes, and No. 1 for one hour and thirty-five minutes. The catgut is then removed and immediately placed in running water for the same length of time that it has been in the formalin solution. It is then dried in the open air at ordinary temperature, labeled and put away for future use. The catgut thus prepared may be handled precisely like silk, from which it differs only in its ultimate absorbability. The approximate time for which material thus prepared may be depended on to furnish support to the tissues is as follows: No. 4, seven days; No. 3, five days; No. 2, three days; No. 1, thirty-six hours. Where it is desirable to support and maintain the tissues in apposition for a long time, a 5 per cent. formalin solution is employed instead of a 3 per cent., and the gut is left in the solution for as long a time as is compatible with the preservation of a fair degree of flexibility. This time has been found to be approximately double that stated for the respective sizes of gut when treated by the 3 per cent. solution. In any case, the washing in running water is carried on for the same length of time used in the immersion in formalin solution. No. 4 gut, treated according to the latter specifications, will remain in the tissues for from four to six weeks, but is subsequently completely absorbed. No. 1 gut prepared by the second process may be used in surgery of the biliary or urinary bladder or their tracts with perfect safety. In obstetric practice No. 3 or No. 4 gut, prepared by the first process, is to be selected. In hernia operations, where there is likely to be considerable traction on the fascia, No. 4 gut will meet all expectations.

60 *Hemorrhage of Syphilitic Origin in the New-born. W. R. Wilson, Philadelphia.
61 Duration of the Prodromal Period in Roetheln. D. J. M. Miller, Philadelphia.

57. **Nervous Exhaustion in Infants.**—Attention is called to this condition by Northrup, and a case is cited of a four-months baby suffering from nervous exhaustion, nervous dyspepsia and prostration, the condition being cured finally by instituting rest treatment and by providing an intelligent nurse. The baby made a good start in life, but after a few months social demands began to wear on the mother and the milk suffered. In addition to all this was the incessant wear on the child's nerves by the noise made by trolley cars and other street traffic and other injudicious excitement, such as waking the baby from sleep, jumping it in the air, etc. Quiet surroundings were provided, the infant was fed in a dark room, all unnecessary noises were either muffled or reduced, and, above all, a wise nurse was given sole charge of the infant. The result was that in a fortnight the baby was feeding on maximum diet, sleeping perfectly, and gaining in weight. It has thrived ever since.

60. **Hemorrhage of Syphilitic Origin in Newborn.**—Wilson says that the clinical manifestations which accompany hemorrhage are various, depending on the development of the infant as to prematurity, on the degree of blood dyscrasia, and probably on the thoroughness of the specific infection. He relates the following cases: 1. Death following umbilical hemorrhage, with wasting and signs of cerebral pressure. Autopsy revealed intracranial hemorrhage. History of syphilis in the mother. 2. Death in a premature infant following umbilical hemorrhage. Clinical evidences of syphilis during life in the form of vesicular eruption on the plantar surfaces. Autopsy revealed subarachnoid hemorrhage; infarction of both kidneys. A history in the mother of previous miscarriage in the third month. 3. Death from asphyxia. Skin hemorrhages in the form of more or less extensive extravasation. Syphilitic enlargement of the liver. Autopsy revealed nothing of interest beyond the liver condition. History of syphilis in the mother. 4. Death immediately following birth in a premature infant. Bleeding from cord; petechial eruption; marked syphilitic degeneration of placenta. 5. Ecchymosis of serous membrane and minute apoplectic areas in lungs. Tubercular syphiloderm in palmar surfaces. Laryngeal obstruction and marked scaling of skin during life. 6. Hemorrhage from mouth and cord complicated by icterus. Typical manifestation of congenital syphilis in the form of emaciation and pallor. Autopsy showed chronic hepatitis and suprarenal hemorrhage. 7. Hemorrhage from cord. Death followed inanition in the course of suppurating gummata of the scrotum and great toe. 8. Still-born infant. Gumma on external border of both feet. Scleral hemorrhage. Autopsy showed subarachnoid hemorrhage; enlargement of the thymus. 9. Still-born infant. Subcutaneous extravasation. Evidence of leakage from the cord after ligation. Bullous eruption of the palmar and plantar surfaces. 10. Still-born infant. Cutaneous hemorrhage. Autopsy showed pericranial and subperiosteal hemorrhage; subcapsular hemorrhage of the liver; syphilitic periostitis and necrosis of the cartilage of the nose existed in the mother.

66 *Duodenal Ulcer Caused by Pressure from Stones in Gall Bladder. G. H. Cattermole, Boulder, Colo.

63. **Short Incision in Laparotomies.**—Holmes points out that surgical incisions are made for the purpose of securing drainage and to give access to the parts. In the former instance there is every reason for a liberal gash, while in the latter case the wound must be closed again, and many reasons exist for an incision as short as possible. In the former case drainage must be adequate, and a longer incision will not detract from this end, while a shorter one is fatal to its purpose. In the latter case the cut must be long enough to reach the protected part, and if it is longer it only adds to the mutilation of the patients and to the disadvantages of closure. In operations about the face, cosmetic reasons exist for making a short incision, and in abdominal incisions for various purposes an extremely short incision prevents at once the disfiguring scar, prevents waste of time and suture, shortens the anesthesia, prevents the operation hernia, allows the patient an almost immediate erect posture and shortens the stay in the hospital. All these advantages encourage early, and therefore safe, operative procedure, diminish greatly the number of years of suffering by the multitude of patients who are deterred from seeking surgical relief by the long period of confinement, the risk of hernia, and the disfiguring scar which a long incision entails.

66. **Duodenal Ulcer and Gallstones.**—Cattermole's patient was suddenly seized with pain in the region of the liver, extending behind to the right shoulder. He soon became moribund; there was no pulse at the wrist; he could not swallow water; the abdomen was very much distended and tympanitic, especially over the liver; there was no peristalsis nor tumor. Death ensued within twenty-four hours. In cutting through the peritoneum, just below the ensiform cartilage, a large amount of gas and brownish fluid escaped. All serous surfaces were congested and there was considerable deposit of fibrin on the intestines and parietal walls. About the liver, stomach and duodenum there were adhesions, showing where fluid had been walled off. The gall bladder was contracted down over two large gallstones, and where the gall bladder came in contact with the duodenum an ulcer had formed, perforating the bowel. This ulcer was on the upper surface of the duodenum, about one-half inch from the pyloric opening of the stomach. The edges of the ulcer were hard and fibrous, showing a long-continued irritation. Evidently, the ulcer was caused by pressure from the gall bladder. The ulcer was largest on the peritoneal surface, sloping toward the opening in the mucosa. The patient had for years led a very sedentary life. thus probably lessening the danger of early perforation.

68. **Fatal Infection by Bacillus Aureus Foetidus.**—The observations reported by Herzog refer to a case of fatal human infection by a hitherto undescribed organism, which is evidently not very pathogenic in ordinary conditions and, as a rule, is probably a harmless saprophyte, which, however, in circumstances especially favorable may become parasitic and cause a fatal issue. The patient died rather suddenly, and it was suspected that he had died of plague, having an open wound on his right leg and a marked swelling of the inguinal glands of the right side. Cultures made from the liver and heart developed pure cultures of a short, small bacillus which produced a golden-yellow pigment. The name *Bacillus aureus fœtidus* was selected for this microorganism because of its chromogenic and malodorous properties. It is a short bacillus with rounded ends, varying in size from 0.6 to 2 microns long and from 0.55 to 0.8 microns in thickness. It frequently presents itself as a diplobacillus, and occasionally is differentiated with difficulty from true diplococci. It possesses a capsule of moderate size Spore formation was not observed. The organism is not motile. It stains readily by the watery anilin stains, and when lightly stained it may show polar granules. Gram's method decolorizes the bacillus. In culture it produces an intense golden-yellow pigment, and all cultures where aërobic or anaërobic have a fetid, cheesy and somewhat cadaverous smell. The thermo death point of the organism was determined to be 62 C. It grows readily on all culture media.

70. **Summer Diarrhea in Infants.**—With a view to solving some of the problems connected with the intestinal diseases in children, the authors undertook to study all the cases of summer diarrhea presenting themselves at a Chicago sanitarium. Cultures were made and studied from 102 cases From 76 cases no bacilli corresponding to any of the types included in the dysentery bacillus group were found. From 26 cases (25.4 per cent.) bacilli were cultivated which possess the cultural properties shown by one or the other member of the dysentery bacillus group. No culture was obtained which corresponded to the true Shiga bacillus Grouped according to the classification of Flexner, 15 cultures from 11 cases correspond to the Flexner-Harris type, and 18 cultures from 17 cases to the bacillus Y type. From 2 cases both these types were obtained. The methods employed in testing the agglutinative properties of organisms obtained from these cases made use of four different strains of dysentery bacilli: 1, Shiga; 2, Kruse; 3, Flexner, and 4, the Y type. Of the 33 organisms examined, 29 gave positive results with one or more of the sera. Of these 29, 9 agglutinated with a single serum, as follows: 3 with Shiga's serum, 1 with Kruse serum, 4 with Flexner serum and 1 with Y serum; 12 agglutinated with two kinds of sera, as follows: 3 with Shiga and Flexner sera; 2 with Shiga and Y sera; 4 with Kruse and Y sera; 3 with Flexner and Y sera. Six agglutinated with three kinds of sera: 2 with Shiga, Kruse and Flexner sera; 1 with Shiga, Kruse and Y sera; 2 with Shiga, Flexner and Y sera; 1 with Kruse, Flexner and Y sera. Two organisms agglutinated with the four different sera employed. So far as the clinical features of these cases are concerned, dysentery bacilli were not found in all cases characterized by mucus and blood stools The group of cases in which dysentery bacilli were isolated from the stools presented the clinical picture of ileocolitis, but these cases did not differ clinically from cases of iliocolitis in which these bacilli were not found.

3 **Sanatorium Treatment of Phthisis.**—Ransom says that the evidence at hand shows that in sanatoriums as now managed from one-fourth to one third of the patients regain their working capacity for at least four years, and is strongly of the opinion that those who survive that period will live longer. Moreover, it is certain that when patients are sent to sanatoriums earlier in the disease a larger number of recoveries will occur. If consumptives are to be treated at all, they are best treated in a special hospital, and such a hospital is best placed on a dry, bracing spot, with plenty of pure country air. Such a hospital is a sanatorium. It would be an advantage if each sanatorium had one or more special out nurses with special training in hygiene to visit patients at their own homes.

4. **Results of Sanatorium Work in Phthisis.**—The total number of cases available for use in this report is 289. The authors divide these into three main classes: (a) Severe (disease affecting either the whole of one lung or considerable areas in both, often complicated with disease of the larynx). (b) Moderately severe (disease affecting not more than one-half of one lung, with or without slight affection of the other—laryngeal diseases occurring in this class also fairly frequent). (c) Slight (disease confined to one lobe of one lung). Class A included 183 cases. Of these 56 died either in the sanatorium or at home within twelve months of commencing treatment. Twenty-three patients died within two years; 30 patients were followed for two years and then lost sight of; 39 patients are in fair health in 1904, and 35 patients are absolutely well (cured). Class B includes 84 cases. Of these 2 died within twelve months, 3 within two years, 19 alive after two years; 11 are in fair health and 40 cases are cured. Class C includes 22 cases. Of these 1 was alive after two years, 1 is in fair health and 20 cases are reported as cured Taking all the classes together, the percentages are as follows: Died in 12 months, 58 cases, 20.06 per cent Died within 2 years, 26 cases, 8.9 per cent. Alive after 2 years, 50 cases, 17.3 per cent. In fair health, 51 cases, 17.6 per cent. Cured, 104 cases, 35.9 per cent.

5. **Iodoform Infusion in Phthisis.**—Dewar makes a further report on the treatment of advanced pulmonary tuberculosis by the intravenous injection of iodoform. Since publishing his first paper, he has modified the solution by adding 40 per cent. of liquid paraffin to it. (The original solution was a not quite saturated solution of iodoform in ether.) Liquid paraffin is perfectly soluble in ether, and the resulting solution is blander and less irritating to the veins. It further makes it possible to use much smaller vessels; in fact, the limit is only defined by the size of the needles and the operator's dexterity. Before using, Dewar filters an ounce or so through cotton wool. He has occasionally used iodoform in liquid paraffin alone in the proportion of one-half grain to 10 minims. This preparation is perfectly workable through fine needles and can be used in tuberculous joints or hypodermically in tubercle of the skin and glands and peritoneum It is painless on injection, and is prepared by crushing the iodoform in the liquid paraffin with a probe in a conical minim glass It is essential to use a non-actinic all-glass syringe Dewar uses a half-grain tabloid of iodoform, which is placed in the syringe, crushed with a piston, the ether drawn in and shaken until the powder is dissolved, when a few minims of liquid paraffin are drawn up and the whole is well shaken. To facilitate introduction, to avoid haste and to prevent any escape the point of the needle is sealed by dipping it in hazeline cream. It is desirable, when possible, to inject in daylight, preferably after 3 p. m, because then the veins are generally fullest Enter the needle vertically and try to pin the top of the curve of the vessel with the point of the needle, and then, pushing it gently on and bringing it into line with the caliber of the tube, insert it half way. The sensation of going into a space is felt at once Dewar reports 9 cases, in five of which the disease was arrested, that is, the condition was changed from a state of danger to one of comparative safety. The patients have lost their cough, and in the occasional sputa only a very few tubercle bacilli can be found, although Dewar attaches no especial importance to this. On the whole, however, Dewar feels that the result in these 5 cases is a good one, as the one

and only factor in the treatment was the infusion of iodoform, and to this he attributes their immediate recoveries. In 2 cases the treatment retarded the advance of the disease. The remaining 2 cases are examples of the severe type of the disease and the slight improvement obtained is all that can possibly be expected. Dewar still contends that the continuous successful injection of an ethereal solution of iodoform is followed by improvement, that it is innocuous in moderate doses, and powerful to arrest pulmonary tuberculosis.

10. X-Ray Treatment of Leukemia.—Ledingham and McKerron report the case of a boy, aged 11, suffering from splenomedullary leukemia, who was markedly benefited by exposures to the action of the *x*-ray. Before beginning treatment there was marked distension of the abdomen, due to an enormous enlargement of the spleen, the lower border of which reached to within a finger's breadth of the pubes, while the anterior border extended two inches beyond the middle line. Examination of the blood showed the characteristic changes of leucocythemia of the splenomedullary type, red cells, 3,570,000; white cells, 234,000, and hemoglobin, 80 per cent. Differential count: Myelocytes, 48 per cent.; polymorphonuclears, 39 per cent.; small and large lymphocytes, 8 per cent.; mast cells, 6 per cent., and nucleated red cells, 4 per 100 white cells. The *x*-rays were applied over the splenic tumor and the lower epiphyses of the femor. Occasionally they were applied over the sternum and vertebræ. The exposures lasted ten to fifteen minutes every alternate day, but for a period daily exposures were given with no bad effects. In fact, throughout the three months of *x*-ray treatment no constitutional effects were noted apart from slight prickling sensations, lasting for a short time after the applications. There was never any nausea, headache, nor rise of temperature traceable to the *x*-ray treatment. The vacuum tube was always fixed at a distance of somewhat over five inches from the area exposed. One month after the treatment was begun a marked erythema appeared over the splenic area, but it subsided in a few days. Within six weeks the leucocytes dropped to 23,000. On one occasion they dropped to 17,800. The mean of the red cells was about 4,500,000, and on several occasions counts of over 5,000,000 were recorded. The hemoglobin appeared to remain fairly stationary at from 55 to 60 per cent. The ratio of polynuclears to myelocytes rose from 0.5 before the *x*-ray treatment to 2. The myelocytes, however, showed no tendency to disappear altogether, and the blood did not return to normal proportions. Previous to this treatment the patient was more or less bedridden, walking was always difficult and breathlessness with face flushings exceedingly troublesome. Within a month after the commencement of treatment he felt better and was able to walk, and even climbed stairs, without any bad effect. The abdominal girth was diminished about two and a half inches within four months. In the same length of time he gained 12 pounds in weight. The splenic tumor was markedly softer on palpation and is constantly diminishing in size.

13. Hemorrhagic Typhoid Fever.—Blair's patient became ill suddenly. She passed blood by rectum, looked drowsy and ill, and complained of pains all over the body. Her pulse rate was 140; respiration, 44; temperature, nearly 105. She was frequently purged during the day, while some of the stools seemed to consist of nothing but blood. Physical examination revealed nothing abnormal. There was no rash, and no enlargement of the spleen could be felt. The temperature gradually dropped to 101.6, but on the third day again rose to 104.8. On the following day a considerable increase in the tumescence of the abdomen was noted. The urine contained blood; *petechiæ* had come out on the legs and arms. At the basis of both lungs râles were audible, bronchophony was well marked and there were small areas of tubular breathing. On the sixth day there was considerable epistaxis and bleeding from the gums. At night she had one "fit" and was purged three times, pure blood being passed on each occasion. She died on the seventh day, after having had six more "fits." In attempting to arrive at a diagnosis, Blair considered purpura hemorrhagica, that form of ulcerative colitis known as acute diphtheritic dysentery, and latent typhoid fever. The autopsy disclosed, in the lower eighteen inches of the small intestine, extensive ulceration of Peyer's patches, several of the ulcers having penetrated down to the peritoneal coat. The ulcers were typical of the third stage of enteric fever, and they stopped abruptly at the ileocecal valve. The disease, therefore, was obviously one of those extremely unusual types of typhoid fever exhibiting a hemorrhagic diathesis. The most remarkable feature of the case was the latency of the early symptoms.

18. Fatty Processes at Apex to Facilitate Its Movements.—Poirier is professor of anatomy at Paris, and here calls attention to a concentric arrangement of fringe-like, fatty processes in that portion of the pericardium which corresponds to the apex. He thinks that they are designed to serve the same purpose as the fatty processes in the knee, to obviate concussions and to facilitate movement. Inflammatory processes, by soldering these leaflets together, must hamper the movements of the apex. In examining the heart of three persons immediately after execution, and in a number of other cadavers, he always found a certain amount of liquid in the pericardium, showing that it is considerably larger than the heart itself. Radioscopy of 50 subjects also always showed traces of an open space during inspiration between the heart and the diaphragm, as if the heart separated from the diaphragm. This he believes is rendered possible by the sero-fatty processes he describes and illustrates. There are usually three, from 4 to 5 cm. long, and they look like a solid mass of sero-fatty tissue, but they can be separated and the three leaflets turned back, exposing an area of the pericardium, 6x10 cm., over the apex.

19. **Conjugal Diabetes.**—Martinet has encountered 5 cases of diabetes in both man and wife among 25 diabetic patients in his city practice. Debove has found 6 cases among 50 diabetics. This is a far larger proportion than that mentioned by Schmitz and Delcage, who noted only 1.12 and 3.55 per cent. among 2,320 and 478 cases of diabetes, respectively. The discrepancy in the statistics, Martinet thinks, is due to the fact that the latter physicians practice in watering places where they see the patients only for a short time and know little of their family life.

24. **Heart Lesions and Kidney Affections.**—Bronowski has been studying the reciprocal action of heart defects and kidney affections, and has become convinced that the routine method of treating heart affections is based on false premises. In 165 cadavers at Warsaw in which some heart or aortic affection had been the principal malady, he found only 6 in which the kidneys did not show some pathologic changes. In 119 there was chronic and in 3 acute nephritis; in 24 there was cyanotic induration, in 13 parenchymatous congestion, and 1 mere hyperemia. Mitral lesions preponderated, 54 mitral to 50 aortic, and 18 in which the two were associated, a total of 122 accompanying unmistakable nephritis. This is a proportion of 74 per cent. He produced artificial heart lesions in 30 dogs, introducing into the left ventricle a fine needle terminating in a hook, with which he tore some of the valves. Only 4 survived the operation long enough for definite conclusions to be drawn. Two of these presented distinct nephritis. He accepts as established the fact that any interference with the circulation in the heart modifies the composition of the blood, and by inducing stasis in the kidneys depresses their vitality. This favors the development of disease, as the toxins are not eliminated naturally by the kidneys. They pile up in the blood and react on the heart in turn. Bronowski believes that the heart lesion is frequently the first link in the chain which leads to kidney disease. The latter may likewise induce heart disease, but this occurs less frequently. The practical conclusions are that the customary treatment of heart affections is irrational and injurious. Instead of trying to stimulate the kidneys to extra work, they should be spared and the patient should be treated as if nephritis were already established. Drugs to regulate the circulation should be prescribed (iodin, iron), mineral waters, dieting, etc. On the other hand, in case of kidney disease, disturbance in the heart functions should be feared, and treatment should aim to prevent extra demands on the heart. Hot baths, exercise and pilocarpin should be avoided, and greater stress be laid on mineral waters, dieting and a dry, tempered climate at a low altitude. The chief aim of treatment in both the heart and kidney disturbances should be to regulate the circulation.

25. **Treatment of Cancer of Tongue.**—Faure insists on the necessity for operating in two sittings in case of cancer of the tongue, unless the lesion is very small. When the glands have to be excised, this should be done first from without, reserving the direct intervention on the tongue for the very last.

26. **Tests of Catgut.**—Hallion and Carrion found that no cultures developed from certain specimens of catgut in the first bouillon, while some developed as soon as the catgut was transferred to fresh bouillon. They discovered that this was due to the fact that the manufacturer had used some antiseptic—sublimate—in the production of the catgut. This had checked the growth of bacteria. When it had dissolved out the bacteria proliferated unchecked.

29. **Successful Treatment of Nephritis with Pigs' Kidneys.**—Page and Dardelin have treated 18 cases of nephritis by giving a maceration of fresh pigs' kidneys. They say that the results have been so remarkable that they do not hesitate to proclaim that this is the most certain and the most powerful weapon at our disposal in fighting with nephritis. The nephritis was of various types in their cases, some long rebellious to other measures and some with pronounced arteriosclerosis. Some of the patients have been examined one, three and eight months afterward, not a trace of recurrence of albumin having been found in any instance. Arrangements are made with a druggist to have him fill the prescription, which reads: "Maceratio renalina porci, No. 1." The remedy might become repugnant to the patients if they prepared it for themselves. The kidney of a freshly slaughtered pig is cut up, rinsed carefully to remove all traces of urine, and then chopped fine and ground to a pulp. This is placed in 300 gm. of cold physiologic salt solution (7.5 gm. per 1,000). It is set aside in a cold place for three hours, stirred occasionally, and is then ready to use. The patient sips all the reddish fluid in three portions during the day, leaving the sediment. The taste is not bad, especially if it is mixed with a little julienne soup. It should be taken for ten consecutive days with milk or milk-vegetable diet, or merely in addition to the ordinary diet. One of his patients had the nephritis of pregnancy, recurring during three pregnancies; albumin in the third month .17 gm. to the liter. The albumin vanished completely and permanently after eight days of the maceration.

Case 1.—Woman of 35, infectious nephritis; albumin 2 gm. to the liter. On exclusive milk diet for eight days, albumin 1.5 gm. Macerated kidney given for ten days: albumin .2 gm.; milk for fifteen days, and after this, albumin 0. Case 2. Man of 58, lead nephritis; albumin .5 gm. on a milk diet. Macerated kidney for ten days with ordinary diet: albumin 0. Case 3. Man of 78 with infectious nephritis and slight arteriosclerosis; albumin 55 gm. to the liter. After a month of milk-vegetable, unsalted food, albumin .51. Macerated kidney: albumin 0. Case 10. Man of 31, infectious nephritis. Scarlet fever six months previously. Macerated kidney for ten days: albumin 0. Case 15. Woman of 60 with arteriosclerosis and uremia; albumin 2.15 gm. to the liter. Under ten days of macerated kidney, milk, intestinal lavage and serum, the albumin dropped to 1.85 gm. and to 0 the week after.

Several other patients had been addicted to morphin and the nephritis was evidently of a toxic nature, with albumin of .4 to 1 gm. In every instance the albumin vanished completely under ten days' treatment with macerated kidney.

33. **X-Ray Treatment of Tinea.**—Sabouraud's communications on the successful application of the *x*-rays to the treatment of parasitic alopecia areata have been summarized in these columns, page 1265 of the last volume. His report for 1904 is even more encouraging. It is no longer necessary to take the children with tinea into the hospital. Ambulant treatment is proving ample, and instead of the two years formerly required, the cure is complete in three months at farthest. The tube should be at a distance of 15 cm. from the patch to be treated, and a scrap of platino-cyanid paper should be exposed to the action of the center of the tube at the same time (equal to 5 Holzknecht units), but at a shorter distance—8 cm. When the thin sensitized paper has changed to the tint B of the radiometer the exposure is terminated. By watching the shade of the sensitized paper the operator can be confident that there is no danger of a burn, erythem or permanent baldness as long as the shade is below the tint B or the 5 Holzknecht units. After the exposure the part is rubbed with a salve containing oil of cade, which is washed off each morning. The entire scalp is then rubbed with a 10 per cent. alcoholic solution of tincture of iodin, to prevent reinfection from the hairs as they drop out of the exposed patch. Each patch requires a separate exposure. There are no by-effects, not even a headache when the entire scalp has thus been exposed.

38 (XXV, No. 2, January 11.) *La néphrite par le sublimé. A. Chauffard.
39 La mortalité de l'anesthésie génerale par la scopolamine-morphine.

38. **Nephritis from Use of Corrosive Sublimate.**—Chauffard's patient was a young woman who had ingested a concentrated solution of corrosive sublimate ordered for vaginal injections. In another case a young woman had taken 5 gm. of the sublimate and 10 c.c. of laudanum. There was complete anuria for five days, then emission of 70 c.c. of an acid urine, very slightly albuminous, but containing casts and epithelial cells. The amount increased to 900 c.c. the ninth day, with death on the twentieth from acute pericarditis and heart failure. The first patient recovered after a period of five days of complete anuria. The urine contained merely traces of albumin. Every case of sudden and complete anuria occurring in a healthy subject, free from any kidney history and without

known cause, should suggest an intoxication, especially if accompanied by serious symptoms of acute gastroenteritis. Mercurial intoxication should be among those suspected, even in the absence of stomatitis and salivation, neither of which were noted in the above cases until after several days. Even if the patients recover, a tendency to nephrosclerosis will probably be left. In the patient who recovered, functional tests of the kidney indicated reduced *permeability* on the part of the kidneys and progressively rising blood pressure. The anatomic lesions in the kidneys in the fatal case reported were such as to indicate that the glomeruli were the only parts of the kidney's spared by the *poison. Consequently, in treating a case of sublimate poisoning, it is useless to give ordinary* diuretics. The only one that can be expected to act is salt solution. More than 3 quarts were injected in four days in the case reported, with eminently favorable results. No one need fear to induce anasarca by injecting these large amounts of salt solution in the complete anuria of these patients. They have lost such large amounts of water by their excessive vomiting and diarrhea that they are in need of water. The arterial pressure is low. The condition resembles that of the anuria in cholera, but the saline infusion should be suspended if the blood pressure rises above normal or if edema develops. Toxic anuria never indicates surgical interference. The only thing that can be done is to overcome the renal obstacle immediately, while the tolerance of the organism still persists. It is a question of life or death, and no temporizing is allowable in anuria.

40. **Arteriosclerotic Abdominal Colic.**—Buch concludes his *monograph on* this subject with a discussion of the pathogenesis and treatment. From a material of 25 cases he preaches that arteriosclerotic colic is in reality neuralgia of the lumbar sympathetic. This fact is established by the exact similarity between the spontaneous pains and those induced by pressure on the sympathetic. Even the *irradiations of the pain* are identical, showing that the colic is, in fact, neuralgia of this portion of the *sympathetic nerve, with possible involvement* of the celiac, aortic and hypogastric plexuses. The neuralgia is due to irritation. The aortic plexus lies close to the aorta, and any inflammation of the adventitia is liable to affect the plexus also. Inflammation of the adventitia is a common occurrence in arteriosclerosis. Periarteritis is an almost constant *accompaniment* of arteriosclerosis, and the involvement of the adjacent nerve is *almost* inevitable. The superior mesenteric ganglion actually surrounds the origin of the superior mesenteric artery, and this is probably the reason why the epigastrium is so frequently the location of the arteriosclerotic pains. The sclerosis *of the* splanchnic vessels *entails, further,* hyperemia or *inflammation of the lumbar* sympathetic *as* an inevitable consequence, *either from sclerosis of the* nerve vessels or collateral congestion. The fact that arteriosclerotic colic usually comes on after physical exertion sustains this assumption. The *additional congestion in* the vessels of the plexuses, induced by exercise, superposed *on the* hyperalgesia resulting from the permanent congestion, must necessarily result in pain. A further factor in the colic is the occurrence of spasms in the vessels. It is possible the congestion may entail excessive functioning on the part *of the suprarenals.* This hypersecretion of adrenalin may induce cramps, *as is seen in experimental research* with it. Vaquez reported last year that his experiments revealed a marked tendency to cramps on the part of sclerosed vessels, and, further, that hyperplasia of the suprarenals was *unmistakably* evident in such cases. Others have reported corroborating findings in nearly a dozen cases of arteriosclerosis, the hyperplasia of the suprarenals observed indicating hyperfunction of these organs. Buch concludes that the process in *angina pectoris* is much like that in arteriosclerotic colic, and they may occur together. Treatment of arteriosclerotic colic based on these premises is remarkably effectual. Strophanthus may not only abort an attack, but may ward off recurrences. As the pain is relieved by pressure on the abdominal plexuses and aorta, massage seems to be *indicated,* combined with Swedish movements. More or less permanently favorable results were obtained in his cases by the medicinal and general treatment outlined. In some of the patients *the manifestations of the arteriosclerotic condition* were banished *for* several years. The prevailing pessimism in regard to arteriosclerosis is not justified. The cases on record of local arteriosclerosis of the extremities, from nervous influences alone, teach that the nervous system *should not be ignored in the treatment.* Both Edels and Basch have observed cases in which the blood pressure was permanently raised by nervous influences, and the latter had occasion to note the development of arteriosclerosis later in such patients. *He calls the condition "latent arteriosclerosis,"* but *Buch thinks that in reality it is one of actual sclerosis, but at this* stage is limited to the splanchnic vessels only.

41. **Determination of Digestive Activity of Gastric Juice.**—*See* The Journal, *xli, page 1229, 1903.*

42. **Absorption of Atropin, Salol, Salicylic Acid and Rhubarb in Stomach.**—Experiments on dogs and cats demonstrated that atropin and rhubarb are not absorbed in the stomach. Salol taken into the isolated stomach of dogs or injected subcutaneously was evidently absorbed, decomposed in the blood and its cleavage product, salicylic acid, eliminated in the urine. Salicylic acid was also absorbed in the stomach and appeared promptly in the urine.

43. **Superficial Dissecting Esophagitis.**—Stern describes a case of this rare affection of which he found only 4 cases recorded in the accessible literature, one from Moscow and one from Warsaw. Birch-Hirschfeld's *patient* was a hysteric woman who expelled a membranous tube 20 cm. long after three days of illness. She stated that she had vomited a similar mass several years before. He explained the affection as a pseudo-croupous inflammation of the esophagus, the process *most acute in the subepithelial* tissues, resulting in the casting off of the epithelial lining. All the patients recovered without formation of cicatricial tissue. The regeneration of the epithelium commences probably under the membrane formation.

45. **Syphilitic Vascular Affections.**—This address, read by von Düring at the recent International Congress of Dermatology, deals especially with syphilitic aortitis and its two forms, the arteritis leading to partial or total *occlusion* of the vessel, and that which reduces the resistance of the walls of the vessels by cicatricial changes. The latter variety he calls Doehle-Heller's syphilitic aortitis, and *regards* it as by far the *most frequent* cause of aneurisms. It is so *characteristic* that a retrospective diagnosis of syphilis can be based on it alone

Syphilis has been demonstrated in the antecedents of from 56 to 85 per cent. of the cases of aneurism on record. He emphasizes that the syphilitic aortitis entailing aneurism has nothing to do with chronic deforming endaortitis, although they may be associated in elderly subjects. The latter may entail rupture, hematoma or dissecting aneurism, but not the true aneurism observed in syphilitics, which develops in young subjects, almost invariably before 50. The wall of the vessel in true syphilitic aortitis consists almost exclusively of a normal or thickened intima with cicatricial connective tissue, lined with endothelium. The media, the musculature and its elastic tissue have been destroyed. The wall of the artery does not offer the normal resistance, and it stretches, even under normal blood pressure, entailing the formation of an aneurism in time. Primary syphilitic lesions of the heart, gummata in the musculature, are rare and generally casual findings. Their slow development and the variability of their site lead to indefinite clinical manifestations. A history of lues and the lack of any other findings may sometimes suggest a gumma in the walls or septum as explanation of vague heart disturbances in younger subjects. Interstitial syphilitic myocarditis is more frequent and more definite. It is usually secondary to aortitis and the consecutive narrowing or occlusion of the coronary arteries. This affection of the coronaries accompanying the dilatation of the aorta and with resulting insufficiency of the aortic valves, and the sequence of cardiac insufficiency, angina pectoris and sudden death form a chain of ills for which the syphilitic aortitis is directly responsible. The benefits obtained by potassium iodid and mercury in the treatment of many affections of the circulatory organs furnish the final demonstration as to their syphilitic nature. Quincke and others have published many instances of remarkable benefit obtained with mercury and iodid in aneurisms when there was apparently nothing to indicate syphilis in the case. Runeberg has reported complete resorption of gummata in the heart walls and muscle under specific treatment. The syphilitic basis also explains the fine results attained in angina pectoris and aortitis with mercury and iodid, especially the latter, given systematically and perseveringly. Even in case of large aneurisms of the aorta and advanced gummatous or indurative myocarditis, great relief is liable to be obtained, although a complete cure can not be anticipated. True syphilitic aortitis should not be classed as arteriosclerosis, as there is no calcification of the artery.

46. **Erythema Nodosum.**—Hoffmann has invariably found an inflammation in the walls of the larger subcutaneous veins in every case of erythema nodosum in his experience. This occurs in both the idiopathic and the symptomatic forms. There is no actual thrombosis, and the process may subside without leaving appreciable traces. In one idiopathic case he found the staphylococcus albus. The inflammation always seemed to start at the forking of the vein.

47. **Plus Pressure Narcosis.**—Engelken adds another to the four modes of applying narcosis while the subject is breathing under plus pressure. His apparatus is designed to allow the anesthetist to sit in the cabinet into which the head of the subject projects. This leaves the operator and his assistants free to operate under normal conditions, with access to instruments, etc., and allows the operation to be done before spectators. The large box or chamber is made light and movable, and the ventilation is so contrived that the fumes of the anesthetic are conducted away without reaching the anesthetist. The other modes of applying narcosis under plus pressure that have been suggested are the use of a diver's helmet for the subject, or of a mask which closes mouth and nose airtight, or Kuhn's intubation, or tracheotomy. The air introduced through the tracheal tube can be under the required plus pressure, as Petersen has practically demonstrated. The details of Engelken's box and its workings are illustrated.

49. **Pseudo-Sclerosis.**—Fickler describes 2 cases which clinically presented the *picture of multiple sclerosis* of the central nervous system, but anatomically, all the signs of it were lacking. He explains the cases as a psycho-neurosis which clinically exhibited a great analogy to multiple sclerosis. Important points for differentiation are the pronounced tremor, frequently of the oscillating type, while the spastic phenomena are less striking than in true multiple sclerosis. Further points are the peculiar changes in the mentality, the emotional excitability and the eventual development of hallucinations. There are only 11 cases of this pseudo-sclerosis in the literature, to his knowledge. The subjects are usually nervous predisposed, either by heredity, syphilis, alcohol or typhoid, although in some cases no inciting cause could be determined. The first symptom is usually a weakness of the legs. The arms may also become weak, and there is sometimes numbness in the hands, strabismus, headaches, pains in the limbs, vertigo or double vision. Permanent paralysis was not observed in any instance, although the main feature of the affection as it progressed was the disturbance in the motor functions. The tremor is the most constant and striking symptom, with twitchings and sometimes disturbances in speech. The tendon reflexes were always more or less exaggerated, but the bladder and rectal functions were not affected. The affection progresses slowly but surely, death generally occurring from exhaustion or intercurrent disease. Thirteen years was the longest limit in any case, the general weakness or exacerbations entailing a fatal termination in about a year in some instances. Certain traits of hysteria may be noticeable in the clinical picture, but Strümpell protests against classing pseudo-sclerosis as hysteria.

54. **Reply to Wada's Article on the Russian Wounded.**—The Japanese surgeon's account of the surgical aid rendered the Russian wounded at Chemulpo was mentioned in these columns on page 433 of the last volume. Banschtikoff produces evidence to show the inconsistencies of the Japanese account, the omissions of certain important data from Wada's personal report, which place some of the results in another light, but he mentions with appreciation the care given the Russian wounded in the Japanese hospitals and their sincere gratitude. He adds that the alleged statements made by the Russians to the Japanese were probably due more to the zeal of the Japanese interpreter than to the Russian speakers.

67 * [illegible] of Sugar in Children.—Die Assimilations-[illegible] im Kindesalter. A. Greenfield.

66. **Human Milk in Catarrh of Small Intestine.**—Salge insists on the necessity for individualizing cases of gastrointestinal disturbances in infants. What is beneficial in certain forms may be harmful in others. Catarrhal conditions in the small intestine cause a clinical picture which suggests that food rich in fat should be avoided as tending to magnify the toxic manifestations. For this reason, breast milk is almost sure to have a highly unfavorable action in such cases. He relates a number of typical experiences to sustain this view.

67. **Limit of Assimilation of Sugar in Children.**—Greenfield's tabulated statistics demonstrate that the assimilation of sugar in children is a matter of age. Neither the weight, nourishment nor certain morbid conditions affect it, but it is directly proportional to the age. By the tenth year it has attained the same limit as in adults.

72 *Anatomische Untersuchungen über den Infektionsweg bei der Genital Tuberkulose des Weibes. (Concluded.) P. Rosenstein (Königsberg).

68. **Results and Prospects of Artificial Premature Delivery.**—Kroemer reviews the experiences at Giessen and deduces the indications to be learned from them. He accepts a true conjugate diameter up to 7 cm. as indication in case of a shallow pelvis, and up to 7.5 cm. in case of a generally contracted pelvis. The bougie and spontaneous delivery are generally sufficient in case version is contraindicated. The hystereurynter with subsequent version and forceps are adapted for all flat pelves, especially for multiparæ. He thinks that the thirty-sixth week is the earliest limit for interference. The average duration of the birth, after the use of bougies, was from twenty-four to forty-eight hours, while with the hystereurynter it was only fifteen. The morbidity in 92 cases of contracted pelvis was 15.4 per cent., but in only 7.5 per cent. were the genital organs responsible for the fever. The mortality was zero. Out of the 82 children born alive, 66 were dismissed in good condition. The generally contracted, shallow pelves gave the highest mortality among the children.

72. **Genital Tuberculosis in the Female.**—Rosenstein's examination of 7 cases of tuberculous affections of the female genitalia always resulted in the discovery that the peritoneum and tubes were affected as well as the ovaries. He doubts whether a tuberculous affection of the ovaries can exist alone. He adds that tuberculosis in the tubes is always bilateral and locates first in the mucosa. Caseous degeneration occurs early in both the tubes and the ovaries. The proliferations suggesting adenoma, which are sometimes found in the tubal mucosa, do not necessarily imply a tuberculous affection. The histologic changes in the tissues of the adnexa affected by tuberculosis are so characteristic that it is unnecessary to stain for bacilli.

73. **Yersin's Serum in Plague.**—Cairns' experience with serum treatment was eminently favorable.

75. **Salicylic Medication Through the Skin for Internal Affections.**—Behr has applied a salicylic preparation in the form of a soft soap in 30 cases of acute rheumatism, chronic arthritis, intercostal or trigeminal neuralgia, migraine, lumbago or pleurisy. He is enthusiastic over the fine therapeutic results obtained when the preparation is massaged into the skin at the most painful points. The presence of salicylic acid in the urine was soon apparent afterward, but it did not cause the usual sweating, and the stomach was spared the irritation from the drug. He applied it once a day for from six to eight weeks, as a rule. His subjects were all tuberculous, as he is assistant in a sanatorium.

77. **"Insect-Bite Icterus."**—Bauermeister had occasion to study in his own person a severe case of icterus with general dyspepsia and gastrointestinal catarrh, preceded by urticaria. The entire syndrome developed while traveling, after a night in which he had been bitten by numerous bedbugs. His trouble proved rebellious, but finally yielded to systematic stimulation of the bile secretion. This he accomplished with salicylic acid and sodium oleate. His personal experience and clinical observation compel him to extol this combination as remarkably effectual for gallstone and similar affections. His formula is .1 gm. each of salicylic acid and the sodium oleate, to which he adds a little menthol and phenolphthalein. He took three or four of these pills morning and evening, with a glass of hot water, sipped slowly, supplemented by a hot-water bottle to the gall-bladder region for an hour or so. He is convinced that systematic use of these therapeutic measures might succeed in many cases where all others fail. He calls attention to Kuhn's recent indorsement of salicylic acid as a bile-promoting remedy. Both he and Kuhn came to this conclusion independently. (Kuhn's work in this line was reviewed in these columns on page 1095 of the last volume.)

80 (IV, No. 23.) *Coloration du bacille de la tuberculose. A. Gabriélidès (Constantinople).
81 *Sur 3 cas de lepra tuberculeuse traités par la méthode mixte de Unna. N. Moraites (Athens).
82 (Nos. 26-27.) *Contact Infection of Typhus. A. Panayotatou (Alexandria).
83 Report of II Panhellenic Congress, Athens, May 17-23, 1903. (Continued.)
84 (V, No. 2.) Oysters and Typhoid Fever in Constantinople. C. D. Remlinger.
85 (Nos. 3-6.) *Systematic Exploration by Large Opening in Case of Abscess in Right Lobe of Liver.—Sur 25 cas d'exploration chirurgicale méthodique des abcès du lobe droit du foie à ciel ouvert. A. P. Petridis (Alexandria).
86 (Nos. 7-10.) Sur quelques troubles de la menopause. M. N. Cairis.
87 Sur 2 cas de chylurie filarienne. C. D. Remlinger (Constantinople).
88 (Nos. 11-12.) *Relations Between Malaria and the Circulatory System. Triantaphyllides, Kanellis and others.

80. **Rapid Stain for Tubercle Bacillus.**—Gabriélidès' technic allows the whole procedure to be done in less than thirty seconds. He modifies the Ziehl formula to the following: 1 gm. fuchsin, 10 c.c. of absolute alcohol, 5 gm. of phenic acid and 40 c.c. of distilled water. He dissolves the fuchsin in the alcohol and mixes the acid with the water, then combines the two and filters. Three drops of this mixture are added to the specimen of sputum, and it is heated for twelve seconds until it steams without burning. The slide is then rinsed and decolorized with 25 per cent. nitric acid in alcohol, rinsed again and stained in methylene blue. The nitric acid decolorizes instantaneously all the elements of the sputum except the bacilli, and the whole process is so rapid that fifteen seconds are ample for the heated sputa and thirty seconds when cold.

81. **Unna's Mixed Treatment of Leprosy.**—Ichthyol internally and externally with sulphur baths and friction of the lesions with ichthyol soap formed the treatment adopted in the 3 severe cases reported. One was apparently entirely cured and the 2 others were very much improved.

82. **Contact Infection of Typhus.**—Panayotatou's patient was a physician attending some cases of typhus in the Alexandria prisons. In giving one of his patients an injection the patient pushed the syringe away and it pricked the physician

in the arm. The spot was disinfected at once, but symptoms of typhus developed after a typical incubation, and the physician succumbed.

85. Large Exploratory Incision in Case of Abscess in Liver.—Petridis gives the particulars of 25 cases of abscess in the liver in which the exact site of the lesion or its character could not be determined, or in which there was a suspicion that there might be more than one abscess. He incises with the actual cautery—seldom with the knife—from the mammary line at the seventh rib toward the axillary line for from 12 to 15 cm. or more, and resects three or four ribs for a distance of from 2 to 3 cm. He then incises the diaphragm with the actual cautery and sutures it with the soft parts to the upper lip of the original incision. Compresses are then worked under the concave surface of the liver, and the organ then can be inspected at ease, palpated and a needle inserted for exploratory puncture as indicated. He gives the details of his 25 cases, insisting especially on the fine results attained by this technic even in extremely debilitated subjects. An illustration of one case shows the gaping wound extending from the mammary line well beyond the axillary line, the incision held open with a retractor, gaping as wide as the diameter of the patient's arm. The horizontal incision along the center of the area of liver dullness allows easy examination of this organ, while the pleural cavity is scarcely infringed on. The benignity of this operation and the extensive oversight it allows over the conditions, permitting the discovery of otherwise inaccessible abscesses, commend it to such a degree that he urges physicians to advise it in the early stages so that the surgeon will be able to interfere in time. The essential features of the operation might be expressed in the term "horizontal polypleurodiaphragmotomy."

88. Relations Between Malaria and the Circulatory System.—This was one of the questions discussed at the last Panhellenic Medical Congress at Athens. Triantaphyllides of Batoum mentioned that in an experience of 12,000 cases of malaria he had encountered 67 in which there was a cardiopathy for which the malaria was apparently directly responsible. Of this number 30 were affections of the endocardium, complicated by pericarditis in 3; 26 were cases of myocarditis; 1 of aortitis and 1 of pericarditis. About 23 of the patients with an affection in the endocardium had some mitral complication, and in 16 there was ulcerative endocarditis. Mantonakis of Crete has found that the heart fibers become atrophied. Manoussos of Athens attributes merely a predisposing influence to the malaria in the production of endocarditis and phlebitis in malarial subjects. He thinks that the hypertrophy of the heart noted in chronic malaria is generally due to interference with the circulation from the enlargement of organs below. He thinks it probable that chronic aortitis may be induced by malaria, and Kanellis of Athens believes that diffuse or, at least, very extensive sclerosis of the vessels is liable to result from malarial infection. He mentions among the functional disturbances encountered in malaria slow or intermittent pulse, gallop rhythm, soft souffles, mesosystolic or mesodiastolic and reduplication of the second pulmonary sound. In very rare instances the malaria may induce an actual organic lesion in the circulatory organs, endocarditis, myocarditis, hypertrophy or dilatation of the heart.

99 *Sea Bathing for Certain Eye Affections.—O lyetchenii nyekotorikh glaznykh zabolyevanii morskimi kupaniyami. S. P. Roshtchevsky.

92. Spinal Analgesia in Gynecology.—Katz advocates spinal analgesia in gynecology when an operation is needed at once and the patient's condition renders either chloroform or ether hazardous.

95. Treatment of Central Placenta Previa.—Liboff agrees with those who advocate cesarean section as the routine treatment in threatening cases of central placenta previa. He describes 3 cases in which it was applied with the best results for both mothers and children. He thinks that a laparotomy is indicated for this serious condition to the same extent as for rupture of an extrauterine pregnancy. The only difference is that in the former case the hemorrhage is external, while in the other, it is internal.

96. Surgery of the Biliary Passages.—Fedoroff analyzes a number of instructive cases from his extensive experience and emphasizes the necessity for co-operation between the physician and the surgeon in this borderland of the affections of the biliary apparatus.

99. The Seashore for Certain Eye Affections.—Roshtchevsky urges that the building up of the general health by a stay at the seashore is a most important factor in the cure of certain affections of the eyes. Beside this, an unmistakably favorable action on the eyes from the sea bathing and from certain mineral waters is unmistakably apparent. He recommends the seashore in a temperate climate as particularly beneficial in case of trachoma.

102. Report of Physician Accompanying Polar Expedition.—Ekelöf was the medical officer attached to the Swedish Antarctic expeditions of 1902 and 1903. He here gives a detailed report of sanitary and health matters, the food and other particulars, with the morbidity. The general health of the party was good for the most part. He gives a number of suggestions important for those contemplating trips to cold regions, especially in regard to prevention of scurvy.

103. School Myopia in Sweden.—Widmark tabulates the statistics from a number of schools and colleges, the proportion of shortsighted pupils constantly increasing with the school demands, as in other countries. He found that girls were more subject to myopia than boys, or at least to its severer degrees, and thinks that this should be borne in mind in selecting a life work. He found normal visual acuity in 97 per cent. of the 418 children in the Djursholms schools (1903), while the proportion was not over 79 in any of the Stockholm schools (1884).

106. Banti's Disease.—Aspelin enumerates among the diagnostic points in this disease the lack of anything in the history to explain the symptoms, their insidious onset in previously healthy or nearly healthy subjects in early middle age, and their chronic course; the moderate anemia of the secondary type without increased leucocytosis, but with increase in the mononuclear elements; the tendency to hemorrhages, and the evening temperature. He has had occasion to observe 3 cases at Helsingfors; the subjects were from 24 to 27 years old, and subjective improvement was obtained with iron, quinin, methylene blue, salicylic acid, or arsenic. One case suggested malaria, which was very prevalent in Finland at the time, but no plasmodia could be discovered in the blood, and its aspect was not that of malaria. Berg's case also coincides with the type established by Banti and Osler, and the patient, a man of 36, recovered complete health after splenectomy in 1897. Lindfors has also reported a case cured by splenectomy.

108. **Appendicitis.**—Perman tabulates the particulars of the 268 cases of appendicitis operated on during the last five years at the Sabbatsberg hospital. The results, he thinks, confirm the benefits of early operating, and of an interval operation after subsidence of even a slight attack.

109-110. **Diazo Reaction in Tuberculosis.**—Widstrand has made more than 2,000 examinations of the urine for the diazo test in 204 consumptives. Forty died in the hospital, and in 37 of these the diazo reaction was constant. In the 3 others the clinical diagnosis of pulmonary tuberculosis was not confirmed by the autopsy. In the mild or chronically latent cases the reaction was almost invariably negative. It is thus valuable for the prognosis and sometimes also for the differentiation. It is especially important when circumstances, such as frequent hemorrhages, forbid physical investigation. The positive reaction may turn the scale in favor of the assumption that the case is too far advanced for hope of a cure.

Holmgren gives excerpts from the hospital records of 158 cases of pulmonary tuberculosis, the results confirming the preceding conclusions. He adds that the stronger the reaction the nearer impending death, the interval not longer than from six to eight weeks. When the diazo is distinct but not strong, the maximal life expectancy can be placed, with great probability, at eighteen months, the average at six months. Among the patients in the third and in the advanced second stage, who presented a dubious or negative reaction, only 16 and 9 per cent., respectively, died within this average limit. A single positive reaction is sufficient for these deductions, and, as the test is so simple and easy, it should be currently adopted as a practical and valuable guide to prognosis. It enables those with a specially unfavorable outlook to be distinguished among the advanced cases and their life expectancy to be stated with greater exactness than by the physical findings alone.

112. **Chronic Arsenic Poisoning.**—Sydow reviews the literature on the subject of arsenic poisoning from wall papers, paint, etc., and advocates, as both convenient and accurate, Gosio's method of detecting the presence of arsenic by the growth of the *Penicillium brevicaule* on the suspected substance. In the presence of arsenic it disseminates a gas resembling the odor of garlic.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Practical Pediatrics. A Manual of the Medical and Surgical Diseases of Infancy and Childhood. By Dr. E. Graetzer, Editor of the *Centralblatt fur Kinderheilkunde* and the *Excerpta Medica*. Authorized Translation, with Numerous Additions and Notes, by Herman B. Sheffield, M.D., Instructor in Diseases of Children, and Attending Pediatrist (O.P.D.). Flexible Cloth. Pp. XII-544. CHYLOUS ASCITES WITH EOSINOPHILIA.

AN ANALYSIS OF REPORTED CASES.*

L. NAPOLEON BOSTON, A.M., M.D.

PHILADELPHIA.

Entering on the subject of chylous ascites, it appears necessary that we consider both chylous and chyloid effusions into the peritoneal cavity, since these two forms of ascites are dependent on entirely different pathologic processes.

True chylous ascites results from the escape of chyle into the peritoneal cavity, this condition resulting from some obstruction to the chyliferous channels. A variety of pathologic conditions may be responsible for the effusion of chyle into the peritoneal cavity; and among these may be mentioned traumatism to the abdomen with rupture of the receptaculum chyli, or of the thoracic duct; obstruction to the flow of chyle through its normal channels, e. g., organic heart disease, as a result of which there is stasis of the innominate vein and venous congestion of the liver; venous thrombosis and peritoneal adhesions surrounding and compressing the thoracic duct, pressure of mediastinal tumors on the thoracic duct; abdominal tumors pressing on the receptacle for the chyle; tumors situated so as to offer obstruction to the flow of chyle in the smaller chyle branches. In this connection malignant growths and tuberculosis of any portion of the peritoneum and of the abdominal viscera may, at times, produce a true chylous ascites, yet such conditions are, as a rule, the cause of pseudochylous ascites. Theoretically, one would expect chylous ascites as a complication during the course of filariasis, although I have found reference to only three such cases.

CHYLIFORM ASCITES.

Chyliform ascites is dependent for its fat on the degeneration of epithelial cells, leucocytes and tissue débris. Such degenerated débris is found in the peritoneal fluid in cases where there are either cancerous or tuberculous nodules of the peritoneum. It is possible to have a true chylous ascites in conjunction with tuberculosis of the peritoneum, as is exemplified in the reported case under my own observation:

DISTINCTIVE FEATURES OF CHYLOUS AND PSEUDOCHYLOUS FLUIDS.

TRUE CHYLOUS EFFUSION.	PSEUDOCHYLOUS EFFUSION.
1. *The fluid consists of a fine emulsion containing but few cellular elements.*	1. A less perfect emulsion containing large numbers of epithelial cells, and granular débris which is seen to display the various stages of degeneration, and to contain few fat droplets.
2. Accumulates rapidly after *tapping.*	2. Collects more slowly, varying with the exciting pathologic cause.
3. Contains sugar.	3. Sugar absent *as a* rule.
4. The melting point of the *fat present in the fluid will be found to vary* with the melting point of the fat taken as food.	4. Fatty foods have no effect on the melting fats contained in the fluid.
5. The amount of fat present is in direct relation with the amount of fats ingested.	5. Not affected by diet.
6. On standing a distinct creamy layer does not collect on the surface of the liquid.	6. A layer may collect which varies with the number *of oil* droplets present. A heavy sediment is liable to *collect* at the bottom of the liquid.
7. Fluid obtained by paracentesis may emit the *odor* of *foods that* have been ingested.	7. Does not *emit* the *odor* of *foods.*

While true chylous fluid always results from an admixture of chyle, Pagenstecher states that the milky appearance of ascitic fluid may depend on fatty degeneration of cells derived from the serous membrane, or on an alteration in an inflammatory exudate—an admixture of mucoid substances. This observer has found true chylous ascitic fluid to display a specific gravity of 1013; to contain 3.6 per cent. of albumin; 2.87 per cent. of fat; and 0.32 per cent. of sugar.

T. V., male, colored, age 11 years, was brought to me for treatment June 11, 1902, on account of loss of flesh and strength. At this time there was no evidence of ascites, the boy's general appearance was that of malnutrition, and he was decidedly nervous. The mother gave me the history that he had been complaining for some weeks past and had lost considerable flesh. His mind was becoming enfeebled, so that when he wandered away from home he was unable to return; he also lost his way about the house, and when sent to one portion of the building would, in many instances, go aimlessly about the house.

When first seen he complained of pain and soreness in the calves of the legs, loins and the arms. Pressure near the tendinous insertions of the calf muscles elicited tenderness and there appeared to be slight edema in the frontal region. I obtained a history of the boy having eaten a large amount of sausage, much of which had not been well cooked, and in view of this fact and the above symptoms I made an examination of his blood the following day.

Blood.—The hemoglobin was found to be 68 per cent.; red cells, 4,760,000, and white *cells,* 8,000 per c.mm. A differential leucocyte count *(600 counted)* gave:

	Per cent.
Polymorphonuclear *cells*	66.0
Basophilic polynuclear	1.5
Transitionals	0.5
Lymphocytes	2.5
Small lymphocytes	1.5
Large mononuclear	2.5
Eosinophiles	25.0
Myelocytes	0.5

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the *Fifty-fifth* Annual Session, June, 1904.

During the counting of 600 leucocytes five nucleated red cells were observed (three normoblasts and two megaloblasts). The existence of a high-grade eosinophilia (25 per cent.), further supported my original suspicion that the boy was suffering from trichinosis. It was not until June 21, 1902 (nine days later), that I was able to persuade the family that an examination of the muscle tissue was necessary.

Examination of Muscle Tissue.—The skin was thoroughly cleansed with bichlorid solution and then with ether, and thoroughly injected with a 2 per cent. solution of cocain hydrochlorate. An incision two and one-half inches long was made over the tendinous insertion of the right soleus muscle, dividing all tissues down to the sheath of the tendon. The tendon was then grasped with a rat-toothed forceps and a longitudinal incision made for about one and one-half inches. The margins of the incised tendon were grasped by forceps and drawn apart by the assistant while I removed a small portion of the muscle.

This muscle tissue was at once placed in water, and later studied for the larval trichinæ, with negative results.

On June 24 (three days later) the wound appeared to be doing nicely and the boy was able to go about the room, but he complained of great weakness and shortness of breath, and of pain and tenderness over the abdomen. An examination of the blood showed red cells, 4,510,000; white cells, 11,500 per c.mm., and hemoglobin, 60 per cent. A differential leucocyte count gave: Eosinophiles, 10 per cent.; myelocytes, 2 per cent. All red cells stained pale, poikilocytosis was rather marked, and there was a slight amount of crenation of the red cells. Few microcytes and a similar number of macrocytes were to be observed.

Treatment and Results.—The patient was placed on predigested foods and tonics. July 22 the blood was again examined and gave the following: Red cells, 5,150,000, increase due to cyanosis(?); white cells, 5,600 per c.mm.; hemoglobin, 52 per cent. A differential leucocyte count gave:

	Per cent.
Polymorphonuclears	71.0
Lymphocytes (small)	13.0
Lymphocytes (large)	6.5
Large mononuclears	2.0
Eosinophiles	5.5
Transitionals	2.0

Film stained with eosin and hematoxylin showed decided decrease in the staining power of the red cells; and these cells were also greatly distorted. There were a number of microcytes and a few macrocytes present. Films stained with carbolthionin displayed well-marked punctate basophilia.

Termination of Case.—The patient continued to grow weaker and the abdominal distension became more and more marked until he was unable to retain his food. There was great pain over the abdomen and repeated paroxysmal attacks of vomiting.

A blood examination, July 26, four days later, gave hemoglobin, 66 per cent.; red cells, 3,390,000; white cells, 3,600 per c.mm. The differential leucocyte count gave eosinophiles, 7.3 per cent. During the counting of 600 leucocytes twenty nucleated red cells were found, three of which were megaloblasts. The red cells stained feebly with eosin, were greatly distorted, and a number of cells in addition to having given up their hemoglobin, were much swollen. These cells displayed little or no affinity for the eosin stain, except a narrow peripheral band of the protoplasm, which was stained of about normal intensity.

September 4, eleven days later, two days prior to death, the hemoglobin was found to have risen to 70 per cent.; the red [illegible] 3,110,000, a loss of [illegible],000 per c.mm.; the white cells, [illegible]. The stained blood presented practically the same [illegible] displayed in the previous examination, except that the [illegible] showed slightly greater affinity for the eosin stain. [illegible] of the red cells and punctate basophilia were [illegible] marked at this time, and the eosinophiles com[illegible] [illegible] cent. of the leucocytes.

[illegible] urine was examined repeatedly and was always [illegible]lly acid in reaction and to display a specific [illegible]22 and 10[illegible]. The quantity of urine for the [illegible] pints. The amount of urea and phosphates present varied greatly in different specimens, but appeared to bear no direct correlation to the severity of his condition. Albumin and sugar were never present. On microscopic examination epithelial cells, few leucocytes, granular débris, crystals of uric acid, and of calcium oxalate were found.

Postmortem Examination.—The body showed decided emaciation, rigor mortis present. The abdomen somewhat distended; there was no swelling of the extremities, and the thorax presented nothing abnormal except emaciation. On opening the thoracic cavity the viscera were found to bear the normal relation to one another.

The pericardium contained about 20 c.c. of clear straw-colored fluid. Its surface appeared as normal. The heart was found to be normal for that of a child of 10 years.

Each pleural cavity contained about 20 c.c. of straw-colored fluid. In other respects the lungs and pleura displayed no gross pathologic conditions.

Abdominal Cavity: On opening the abdominal cavity it was found to be filled with about five and one-half pints of milky fluid. The intestines were covered with lymph-like exudate. In many places the intestines were matted together and portions of the chylous exudate were entirely separated from the general peritoneal cavity by rather well-organized adhesions. It was found necessary to break these adhesions before removing the chylous fluid. The peritoneum covering the intestine, mesentery and peritoneal wall was studded with fine tubercles, the largest of which was the size of a small pin's head; and on using a handglass the entire peritoneal surface was seen to be studded with minute tubercles.

The mesenteric lymph channels were greatly distended, and in many places stood out as small white wires underneath the peritoneum. Some of these distended vessels were almost white, while others were much darker in appearance; and this variation in shade appeared to depend, for the most part, on the amount of tissue overlying the distended lymph duct.

The renal and peritoneal lymphatic plexuses were everywhere greatly enlarged, and some of them were tortuous in their course and appeared to display fine nodules, but it was very difficult to show conclusively that these nodular masses were not small tubercles. The mesenteric lymph glands were slightly enlarged and on microscopic study gave evidence of tuberculous involvement.

The receptaculum chyli was not greatly distended, although it was possible to outline it rather easily. The thoracic duct was found with some difficulty, and was patulous throughout its entire length. At no point did the peritoneal adhesions appear to obstruct the lumen of the duct.

The liver was of normal size, its capsule studded with small tubercles. On section the parenchyma appeared to be fatty, pale and displayed few small tuberculous growths. The hepatic ducts were apparently normal. The spleen was but slightly enlarged, and its capsule showed many tubercles, which on section were found to extend into the splenic pulp.

The kidneys were surrounded by plexuses of greatly distended lymph channels. On section the right kidney was somewhat cyanosed and contained two small tubercles. The left kidney was like its fellow.

The adrenals were apparently normal.

Reports of 126 cases were collected from the literature and these in conjunction with two additional cases have been tabulated as to age, sex, existing abdominal conditions, treatment and result (Table 7).

The cases have been classified also as to exciting cause, e. g., Table 1 setting forth the characteristic features, primary seat of disease, and remarks in 24 cases of chylous ascites complicating carcinoma; Table 2 describing in a like manner 17 cases resulting from tuberculosis; Table 3, 11 cases accompanying cardiovascular conditi[illegible] 4. 8 [illegible] due to disease of the liver; Ta[illegible] fol[illegible] puerperal sepsis; [illegible] sis. Table 6. 4 cas[illegible] c[illegible] where chylous

In addition

ascites followed infection with the filaria sanguinis hominis. Obstruction to the thoracic duct was observed postmortem in 11 of the cases, and the duct or receptaculum was found to be ruptured as the result of traumatism in 7 of the cases.

Sixty-one of the cases were females, 50 males, and in the remaining reports the sex was not given. A further analysis as to the number of cases occurring at the various periods in life gave 6 under 1 year of age; 3 between 1 and 5 years; 13 between 5 and 10 years; 9 between 10 and 20 years; 12 between 20 and 30 years; 34 between 30 and 50 years; and 24 after the age of 50.

TABLE NO. 1.

Cases of Chylous and Chyliform Ascites Complicating Cancer of the Abdominal Viscera, Peritoneum, or with Metastasis to Abdominal Structures.

No. 1. The peritoneal effusion was purely chylous. Thought to have been caused by pressure on the thoracic duct. The growth involved the peritoneum surrounding the thoracic duct.

No. 2, 39 years, female. Effusion chylous. Pressure on the thoracic duct the result of metastasis, and consequent enlargement of the mesenteric glands.

No. 3, 39 years, female. Character of effusion not stated. There were present infiltration of the stomach and also of the mesentery with occlusion of the lacteals.

No. 4, 56 years, female. Carcinoma of the stomach which caused questionable pressure on the thoracic duct. The peritoneum was normal, as was also the receptaculum chyli. The kidneys gave evidence of chronic interstitial nephritis.

No. 5, 52 years, female. Carcinomatous growth, probably from the pancreas, causing pressure on the thoracic duct. Peritoneum not involved.

No. 6, 57 years, female. Carcinoma of the stomach, which probably pressed on the thoracic duct. No mention is made of involvement of the peritoneum.

No. 7, 43 years, female. Cancer of the pancreas with involvement of the peritoneum. Pressure on the thoracic duct questionable.

No. 8. Cancerous involvement of the mesentery—secondary (?). There was present obstruction to the lacteals.

No. 9, 58 years, male. Malignant disease of both the peritoneum and of the pleura. Probably carcinoma.

No. 10. The lesions described point to cancer of the mesenteric portion of the peritoneum. These changes may have been secondary (?).

No. 11, 42 years, male. Metastatic carcinoma of the peritoneum. There was enlargement of the abdominal glands and thought to be pressure on the thoracic duct. The peritoneal fluid was regarded as chylous.

No. 12, 59 years, male. Cancerous infiltration of the liver, mesenteric glands and peritoneum. The peritoneal fluid was chyliform in character.

No. 13, 44 years, female. Metastatic carcinoma of the peritoneum; effusion probably chyliform.

No. 14, 50 years, female. General carcinoma of the mesentery and of the peritoneum, with questionable obstruction to the thoracic duct.

No. 15, 59 years, female. Primary carcinoma of the gall bladder, with secondary involvement of the liver. There was also cancerous involvement of the mesenteric glands.

No. 16, 67 years, female. Carcinomatous involvement of the peritoneum. The report was now clear as to pressure on the thoracic duct. The ascitic fluid was regarded as chylous.

No. 17, 39 years, male. Metastatic carcinoma of the peritoneal glands. There was pressure on the thoracic duct, as the result of glandular enlargement. The fluid was chylous.

No. 18, 35 years, female. Carcinoma involving the peritoneum. Obstruction to the thoracic duct, probably caused by adhesions. The peritoneal fluid was regarded as chylous.

No. 19, 67 years, female. Diffuse carcinoma of the peritoneum. There was no evidence of pressure on the receptaculum chyli or on the thoracic duct.

No. 20, 47 years, female. Carcinoma of the ovary with metastasis to the adjacent peritoneum.

No. 21, 39 years, female. Carcinoma of the stomach with secondary involvement of the peritoneum and contiguous structures. Occlusion of the thoracic duct.

No. 22, 53 years, male. Obstruction of the smaller chyle vessels, as the result of metastatic carcinoma of the mesentery.

No. 23. Gastric carcinoma. It was thought that the thoracic duct had become involved in the growth. Chylous fluid escaped into the peritoneal and pleural cavities.

No. 24. Cancerous growth of the abdomen. The thoracic duct was compressed by the growth and there was a chylous effusion into both the peritoneal and pleural cavities.

TABLE NO. 2.

Cases of Chylous and Chyliform Ascites Complicating Tuberculosis.

No. 1, 59 years, male. Tuberculosis of the lung and of the peritoneum. Diagnosis confirmed at autopsy.

No. 2, 59 years, male. Pulmonary tuberculosis with tuberculosis of the peritoneum. Ascitic fluid milky.

No. 3, 8 years, female. Tuberculosis of the peritoneum with a large chyliform effusion into the peritoneal sac. Tuberculous involvement of the lung found at autopsy.

No. 4, 27 years, female. There had been involvement of the glands of the neck during childhood, and later tuberculosis of the lung. At postmortem the abdominal cavity contained 3,400 c.c. of chyliform fluid. There were present extensive peritoneal adhesions.

No. 5, 33 years, female. The condition of the peritoneum appeared to be primary, and from the description given it was probably of tuberculous nature. Fluid regarded as chylous (?).

No. 6, 10 years, female. Reported as a case of tubercular peritonitis, from which 5,000 c.c. of milky fluid were removed during life.

No. 7, 39 years, female. Tuberculosis of the peritoneum. Everywhere the peritoneum was found to be studded with small tubercles. There were also extensive peritoneal adhesions.

No. 8, 12 years, female. There had been tuberculosis of the superficial glands for a long period. Miliary tuberculosis ensued and was complicated with chyliform ascites.

No. 9, 13 years, male. History of pulmonary tuberculosis, with secondary involvement of the peritoneum. Character of fluid probably chyliform.

No. 10, 7 years, female. At postmortem the peritoneum and peritoneal glands were found to be tuberculous. On section many of these glands were caseous, and contained the characteristic features of tuberculous disease. The fluid was referred to as being oily.

No. 11, 7 years. At postmortem the mesentery was found to be thickened. There were also nodules in the abdominal cavity which, on section, presented the characteristic features of tubercles.

No. 12, 59 years, male. Tuberculosis of the peritoneal sac following tuberculosis of the lung.

No. 13, 10 years, male. There was found at autopsy a chronic tuberculous process involving the peritoneum. At various tappings 6,350 c.c. of fluid were removed.

No. 14, 58 years, female. Tuberculosis of the genital tract, followed by tuberculosis of the peritoneum and of the liver. The patient was tapped four times, and 3,250 c.c. of milky fluid removed.

No. 15, 10 years, male. Autopsy disclosed tuberculosis of the peritoneum, and many adhesions. The chylous effusion was thought to have been caused by adhesion constricting the receptaculum chyli. About 1,000 c.c. of peritoneal fluid were removed at section.

No. 16, 45 years, female. There was present at autopsy miliary tuberculosis of the pleura, peritoneum and pericardium. The patient was tapped repeatedly, and a large quantity of fluid removed from the different sacs at each tapping; the specific gravity of the fluid was 1015.

No. 17, 11 years, male, negro. Tuberculosis of the peritoneum and obstruction to the lacteals. Peritoneal adhesions which divided the peritoneal cavity into many compartments. Peritoneum covered with plastic exudate. Omentum shrunken; 1,200 c.c. of chylous effusion; specific gravity, 1014. The blood showed a high-grade eosinophilia.

TABLE NO. 3.

Recorded Cases in which Chylous Ascites Was Found to Follow Valvular Heart Disease.

No. 1, 43 years, female. At autopsy there was found to be mitral and tricuspid insufficiency. The thoracic duct was obstructed at its point of opening into the vein, the result of a large fibrinous clot. The lumen of the thoracic duct was expanded and its walls thickened; the vein was also dilated at this point.

No. 2, 3 months, male. There existed congenital insufficiency of the cardiac valves.

No. 3, female. History of valvular heart disease of long duration. There was present during life stasis of the venous system.

No. 4, male. Valvular heart disease with venous stasis.

No. 5, 24 years, male. General arterial sclerosis; insufficiency of the cardiac valves. Chronic parenchymatous nephritis.

No. 6, 19 years, male. The thoracic duct was obstructed near its opening into the vein by pressure the result of a fibrinous clot surrounding vegetation which developed from the subclavian vein. At postmortem the receptaculum chyli was found to be ruptured.

No. 7, 19 years, male. Pressure on the thoracic duct by a clot occupying the subclavian vein. This clot was light in color, ragged and rather well organized. There were present, antemortem, cardiac insufficiency and venous stasis.

No. 8, 24 years, male. At autopsy the left subclavian vein was found to contain a large clot. The symptoms were those of cardiac insufficiency, with cardiac dilatation (?).

No 9, 80 years, male. The reporter of this case attributed the chylous ascites to pressure on the thoracic duct, the result of adipose tissue. From the general description of the case, and in view of the fact that there was no autopsy, I have classified it as one of cardiac insufficiency.

No. 10, male. At autopsy there was found to be embolus of the pulmonary artery. There was also a questionable statement as to cardio-vascular disease. The thoracic duct was ruptured.

No. 11, 8 years, male. Disease of mitral and aortic valves. There had been three attacks of acute rheumatism several years before.

TABLE NO. 4.

Chylous Ascites Complicating Disease of the Liver.

No. 1, male. Reported as a case of disease of the liver (?) complicated with chylous ascites.

No. 2, 28 years, female. Fatty degeneration of the liver, with fatty effusion into the peritoneal cavity.

No. 3, 47 years, male. Reported as a case of atrophic cirrhosis of the liver.

No. 4, 39 years, male. Atrophic cirrhosis of the liver. History of alcoholism.

No. 5, 38 years, male. Cirrhosis of the liver, with a history of alcoholism.

No. 6. Cirrhosis of liver with a history of alcoholism.

No. 7, 52 years, female. Cancer of the liver, probably secondary to cancer of the peritoneum.

No. 8, male. Cirrhosis of the liver; cause obscure.

TABLE NO. 5.

Recorded Cases of Chylous and Chyliform Ascites Complicating Puerperal Sepsis.

No. 1, female. There was abortion with delivery of twins. The patient did badly, and probably had puerperal sepsis. The report of the autopsy does not throw further light on the case.

No. 2, female. Following a miscarriage chylous ascites developed. More than 7 liters of chylous fluid were removed by tapping. The patient made an uninterrupted recovery.

No. 3, female. Following labor (with twins) a questionable abdominal tumor developed, which proved to be chylous ascites.

No. 4, 55 years, male. Following an unusually difficult labor there developed abdominal distension, which proved to depend on a chylous cyst. This cyst was evacuated by aspiration, and recovery followed.

No. 5, female. During the first week following delivery the mammary secretion lessened and became abnormal. Other evidences of puerperal sepsis appeared to be wanting. *The chylous effusion was* removed by aspiration and recovery followed.

No. 6, 24 years, female. Following puerperal sepsis there was abdominal distension due to chylous ascites. The abdominal cavity was drained through the vagina and five pints of chylous fluid recovered. Recovery followed.

No. 7, 33 years, female. Abortion at the third month followed by sepsis, with a temperature of 104 degrees, and a pulse of 140 per minute. Chylous fluid accumulated in the peritoneal cavity. Dr. George I. McKelway opened the peritoneal cavity through the posterior cul-de-sac, and one and one-half pints of chylous fluid escaped. Recovery.[1]

TABLE NO. 6.

Chylous Ascites the Result of Congenital Cysts.

No. 1, birth, female. A large congenital cyst ruptured, probably during birth. The chylous effusion into the peritoneal cavity is said to have been large. Fluid removed by tapping and the child made a perfect recovery.

No. 2, male. Laparotomy for removal of a large tumor which proved to be a chylous cyst. Patient made an uneventful recovery.

No. 3, 5 months, female. The patient was tapped and chylous fluid removed. Laparotomy showed the mesentery to contain several chylous cysts. The condition was probably congenital. Convalescence was soon established and recovery followed.

No. 4, 5 weeks, male. Reported as a case of lymphangioma of the peritoneum. The fluid was evacuated by aspiration, and for this reason it appears probable that this case should be considered as one of chylous ascites due to a congenital cyst. Recovery.

TABLE NO. 7.

Reference to Chylous Ascites.

No. 1, female. Obstruction of lymphatic glands and vessels. Medicine and tapping; died.

No. 2, 2 years, male. Compression of thoracic duct near subclavian vein by large tumor, producing rupture of lacteals. Tapping; died.

No. 3, 24 years, female. Childbed, rupture of chyle channels, five pints milky fluid escaped. Counter-opening; recovery.

No. 4, 39 years, male. Calculus in receptaculum chyli. Tapping; died.

No. 5, female. Effort to raise burden, with questionable rupture. Tapping.

No. 6, female. Abnormal mammary secretion during first week of puerperium. Medicine and tapping; recovery.

No. 7, female. Metrorrhagia, miscarriage, unusual exercise, 7.3 liters of chylous fluid were removed; s. g. 1022. Tapping; recovery.

No. 8, 29 years, female. Arrest of secretion of milk from mammary glands and derangement of intestinal canal. Tonics; recovery.

No. 9, female. Premature birth of twins, septic infection questionable. Found at autopsy.

No. 10, 8 years, female. Rupture of lacteal vessels; protracted illness. Tapping; recovery.

No. 11, male. Supposed to be liver disease with large chylous effusion into peritoneal cavity. Medicine; died.

No. 12, female. Abdominal tumor following pregnancy with twins. Rupture at navel; died.

No. 13, 20 years, male. Tumor of mesenteric glands, lacteals large and tortuous. Died.

No. 14, 59 years, male. Chronic bronchitis, asthma, tuberculosis. Questionable tuberculosis of peritoneum. Died.

No. 15, 59 years, male. Tuberculosis. Died.

No. 16, 28 years, female. Chronic peritonitis with fat in effusion. Fatty degeneration of liver and lipemia. Died.

No. 17, 8 years, female. Symptoms of tuberculous *peritonitis*, numerous tubercle in lungs. Died.

No. 18. Milky fluid obtained from abdomen, cause questionable.

No. 19, 62 years, female. Occlusion of thoracic duct with soapy peritoneal fluid; cause obscure.

No. 20, 19 years, male. Partial obstruction of duct near its termination due to adhesions and pressure. Died.

No. 21, 24 years, male. Left subclavian vein plugged with ragged clot. Tapping; died.

No. 22, *43 years, female.* Mitral and tricuspid insufficiency, thoracic duct plugged at outlet with pale and red fibrous coagula; walls thickened; lumen dilated with thrombi. Died.

No. 23. Rupture of chyle vessels from pressure of tumor. Died.

No. 24, 27 years, female. Scrofula, pulmonary tuberculosis, oily ascites, peritoneal adhesions, 3400 c.c. of fluid were recovered. Died.

No. 25, 2 months. Abdominal tumor, causing rupture of thoracic duct. Tapping; died.

No. 26, 30 years, female. Obstruction of thoracic duct due to infarction. Thickening of ureters, 13,500, c.c. of chylous fluid were recovered, probably by repeated tappings. Tapping; *died.*

No. 27, 50 years, male. Traumatic rupture of thoracic duct, effusion into peritoneal and pleural cavities, 20,000 c.c. of chylous fluid were recovered by a number of tappings. Tapping; died.

No. 28, 33 years, female. Primary peritonitis with hydrops adiposus and 8,000 c.c. of chylous fluid were removed. Tapping;

No. 29, 10 years, female. Tuberculous peritonitis, 5,000 c.c. of chylous fluid were recovered. Tapping; died.

No. 30, female. Chylous fluid vomited; also found in peritoneal and pleural cavities; cause obscure. *Tapping; recovery.*

No. 31, 39 years, female. Peritoneum studded with tubercles. Tapping; died.

No. 32, 39 years, female. Puncture of chyle vessels by parasites. Tapping.

No. 33, birth, female. Rupture of a congenital chylous cyst with large chylous effusion. Tapping; recovery.

No. 34, 11 years, male. Ascites following infectious diseases; cause obscure. Tapping. Died.

No. 35, 50 years, female. Rupture of mesenteric and lymphatic lacteals; cause questionable. Tapping.

No. 36, 25 years, male. Syphilis. Tapping; died.

No. 37, 12 years, female. Scrofula and miliary tuberculosis, milky fluid containing fat and the fatty acids. Died.

No. 38, 47 years, male. Cirrhosis of liver; abdominal fluid milky and contained fat. Died.

No. 39, 39 years, male. Alcoholism with cirrhosis of liver; fluid first two tappings ordinary, afterward milky and fatty. Tapping; died.

No. 40, 8 years, male. History of acute attacks of rheumatism, valvular heart disease. Tapping; died.

No. 41, 2 years 8 months, male. Syphilis. The patient had *diabetes, 13,000 c.c. of fluid* were removed. Four tappings; died.

No. 42, 55 years, male. Chylous cyst of abdomen when fluid was found following hard labor. Tapping; recovery.

No. 43, 3 months, male. Chronic peritonitis with congenital heart disease. Tapping; recovery.

No. 44, 13 years, male. Pulmonary tuberculosis with tuberculosis of the peritoneum and chylous peritoneal effusion. Tapping; died

No. 45, 61 years, male. Extensive peritoneal effusion of chylous fluid. Exciting cause undetermined. Tapping; died.

No. 46, 19 years, female. Violent exercise followed by an effusion of chylous fluid. Laparotomy; recovery.

No. 47, 39 years, male. Chylous cyst of the mesentery, which was evacuated. Laparotomy; recovery.

No. 48, 80 years, male. Stasis of the thoracic duct induced by pressure exerted from an accumulation of fatty tissue. Chylous exudate into the peritoneum recovered at postmortem. No autopsy; died.

No. 49, 47 year, male. Chylous effusion into the peritoneal cavity. *Exciting* cause questionable. History of alcoholism. Tapping.

No. 50, 38 years, male. Alcoholism, cirrhosis of liver with chylous effusion. Tapping.

No. 51, 11 years, child. Sarcoma of omentum. Died.

No. 52, 28 years, male. Traumatic rupture of receptaculum chyli. *Tapping*; died.

No. 53. Carcinoma of peritoneum with obliteration of thoracic duct as the result of pressure (?). Tapping; died.

No. 54, 39 years, female. Carcinoma of mesenteric glands, with pressure on the thoracic duct and receptaculum chyli. Tapping; died.

No. 55, 61 years, male. Chronic lymphangitis of the thoracic duct. Tapping; died.

No. 56, 39 years, female. Cancerous infiltration of the lymphatics of the stomach, intestine and mesentery. Lacteals were occluded Tapping; died.

No. 57. Hepatic cirrhosis and chronic peritonitis with obstruction of lacteals and stasis. Tapping; died.

No. 58, 52 years, female. Peritoneal carcinoma with involvement of the liver. There was obstruction of the lacteals of the mesentery. Tapping; died.

No. 59, 5 months, female. Numerous congenital (?) *cysts of the* mesentery which were excised and drained. Tapping and laparotomy; recovery.

No. 60, 42 years, female. Thought to have been either cancer or tuberculosis of the peritoneum. Tapping; died.

No. 61, 61 years, male. The renal and peritoneal lymph plexuses were *greatly* enlarged, as were *also those* of the intestine. These lymph vessels were tortuous in their course, constricted in places and displayed a varicose appearance. Tapping; died.

No. 62, 34 years, female. No autopsy, large peritoneal effusion of chylous fluid. Died.

No. 63, 54 years, male. Profuse peritoneal effusion of chylous fluid, which reappeared *rapidly after tapping.* Said to have been tapped 49 times; died.

No. 64, 31 years, female. Thought to have been a minute perforation of thoracic duct. There was also effusion *into the pleura* The *abdominal* effusion of *chylous* material was *removed and* soon reappeared after each removal. Five tappings; died.

No. 65, 61 years, female. Cause questionable, supposed *to be* rupture of lacteals as the result of traumatism, or *possibly* the condition depended *on infection through* the wound. Tapping; died

No. 66, 41, male. Exciting cause not known; fluid reappeared after tapping. Two tappings; died.

No. 67, 56 years, female. No lesion found in the *chyliferous* vessels. Gastric *cancer present and* sclerotic kidney. Two tappings; died.

No. 68, 53 years, female. Carcinoma involving the *thoracic* duct, but no sight of rupture could be detected. Laparotomy; died

No. 69, female. Cause doubtful; fluid reappeared after tapping Tapping; died.

No. 70, 57 years, female. Cancer of the stomach; thoracic duct could not be found, probably *involved in the growth.* Tapping; died.

No. 71, 21 years, female. No autopsy. Thought to *have been* caused by pressure on the thoracic duct. Tapping; died.

No. *72, 18 years, female. Angiosarcoma* of ovaries, fluid accumulated *rapidly after* removal. Three tappings and laparotomy; died.

No. 73, 46 years, male. Enlargement of the *abdomen* with obliteration of the thoracic duct. There was also chylous effusion into the pleural cavity. Tappings and medicines.

No. 74, 7 years, female. There was enlargement of the mesenteric glands, many of them showing degeneration and chalky deposits on section. Died.

No. 75, 21 years, female. Prolonged attack of chylorosis. The effusion of chylous liquid into the abdominal cavity *was thought* to be due to pressure on the lymph channels *by enlarged* spleen. Tappings and medicines; recovery.

No. 76, child. Abdominal cavity filled with milky fluid evidently derived from rupture of chyliferons vessels. No lesion of the vessels was found. Died.

No. 77, 7 years, male. Mesentery *cirrhosed* and showed many areas, which on sectioning were white and chalk-like—tubercles (?). Died.

---

[1] I am not aware that Dr. McKelway has reported this case and it should be credited to him. I was his resident physician at the time of this observation, and made a chemical and microscopic study of the chylons fluid.

No. 78, 19 years, male. Fibrinous vegetations attached to intima of subclavian vein; partial obliteration of thoracic duct near its outlet; rupture of receptaculum chyli. Died.

No. 79, 24 years, male. Left subclavian and its effluent branches plugged with a light colored and ragged blood clot. No lesion of abdomen found. Tapping; died.

No. 80, 9 years, male. General health fair, no cause discovered. Twenty-eight pints of fluid were recovered from the abdominal cavity during the period of 28 days. The fluid was chylous and had a specific gravity of 1015. Tapping; under observation when reported.

No. 81, 2 years, male. Previous health good, no cause discovered. Abdominal fluid milky and contained lymph cells. Tapping; under observation when reported.

No. 82, male. Chronic lymphangitis involving the peritoneal lymph channels. Died.

No. 83, 59 years, male. Pulmonary tuberculosis, with probable involvement of the peritoneum (?). Died.

No. 84. Lesion of the thoracic duct. (I was unable to ascertain the exact nature of this lesion from an abstract.) Died.

No. 85. Chronic peritonitis with obstruction of the lacteals of the mesentery, resulting in a questionable chylous effusion. Died.

No. 86, 43 years, female. Cancer of the pancreas with cancerous involvement of the peritoneum, 1400 c.c. of chylous fluid were removed at operation. Laparotomy; died.

No. 87, male. Rupture of the thoracic duct; there was also an embolus of the pulmonary artery. Died.

No. 88, female. Chylous effusion—valvular heart disease with stasis of the vena cava.

No. 89, male. Hepatic cirrhosis with chylous effusion into the peritoneum. Died.

No. 90, male. Chylous effusion following valvular heart disease. Died.

No. 91, 54 years, female. Lymphangitis involving peritoneal vessels. Died.

No. 92, male. Questionable chylous. Tapping; died.

No. 93, 10 years, male. Chronic tubercular peritonitis with chylous effusion of 6,350 c.c. of fluid. Tapping; died.

No. 94. Obstruction to the thoracic duct of questionable origin. died.

No. 95. Cancer of the mesentery with obstruction of lacteals. died.

No. 96, 56 years, male. Cause unknown; 28,700 c.c. of fluid were recovered. Five tappings; died.

No. 97, 58 years, female. Tubercular peritonitis, tuberculosis of liver and of the genitalia; 3,250 c.c. of fluid were removed. Four tappings; died.

No. 98, 58 years, male. Malignant lymphoma of peritoneum and pleura; 17,750 c.c. of milky fluid were removed from both serous cavities. Three tappings; died.

No. 99. Malignancy of the peritoneum with chylous effusion.

No. 100. Sarcoma of the mesentery with removal of 50,000 c.c. of chyliform fluid. The S. G. 1011-1014. Four tappings; died.

No. 101, 42 years, male. Carcinoma with metastasis to the peritoneum, mesenteric glands, etc., with pressure on the thoracic duct; 9,600 c.c. of chylous fluid were removed. S. G. 1015-1017. Two tappings; died.

No. 102, 59 years, male. Carcinoma with metastasis to the lymph glands, liver and peritoneum; 400 c.c. of chyliform fluid were removed. S. G. 1020. The fats averaged .31 per cent. Section; died.

No. 103, 24 years, female. Traumatism with rupture of the chyle vessels. Died.

No. 104, 35 years, female. Chronic peritonitis, uterine fibroid with chylous effusions. Tapping; recovery.

No. 105, 35 years, female. Cancerous peritonitis; 8,500 c.c. of chylous fluid removed. Four tappings; died.

No. 106, 67 years, female. Peritonitis and general carcinomatosis; 6,000 c.c. of fluid were removed. Three tappings; died.

No. 107, 67 years, female. Chronic peritonitis with distention of the thoracic duct and chyle receptacle. Three tappings; died.

No. 108, female. Chronic peritonitis with cirrhosis of the liver. Tapping; recovery.

No. 109, 15 months, female. Chronic peritonitis. Nineteen tappings; recovered.

No. 110, 10 years, female. Tuberculosis of the peritoneum with istention of the receptaculum chyli; one gallon of fluid was reovered. Laparotomy; recovered.

No. 111, 46 years, female. Valvular heart disease with parenhymatous nephritis; 1,200 c.c. of fluid were removed. Died.

No. 112, 47 years, female. Cancer of the ovary. S. G. of fluid 011-1015. Died.

No. 113, 44 years, female. Carcinoma with metastasis to the eritoneum and large chylous effusion; 17,000 c.c. of chyliform luid were removed. S. G. 1020, containing 3.98 per cent. of fat. hree tappings; died.

No. 114, 50 years, female. Cancer of the peritoneum and mesntery; 19,000 c.c. of milky fluid were removed antemortem. Taping; died.

No. 115, 45 years, female. Miliary tuberculosis of the peritonum, pleura and pericardium, with obstruction to the chyle vesels; 10,000 liters of milky fluid were removed. S. G. 1015. Three tappings; died.

No. 116, 59 years, female. Carcinoma of the gall bladder with ancerous involvement of the mesentery and liver. S. G. 1012; the t averaged 1.15 per cent. Three tappings; died.

No. 117, 10 years, male. Enlargements of retroperitoneal glands, with pressure on the thoracic duct and a large chylous effusion. Section; died.

No. 118, 67 years, female. Carcinoma of the peritoneum with 17,500 c.c. of chylous fluid. S. G. 1020. Four tappings; died.

No. 119, 39 years, female. Gastric carcinoma with involvement of the liver, peritoneum and infiltration causing obstruction to the thoracic duct; 4,500 c.c. of fluid were removed. S. G. 1012. Tapping; died.

No. 120, 36 years, male. Carcinoma with metastasis to the retroperitoneal gland and to the mesentery with pressure on the thoracic duct; 7,300 c.c. of chylous fluid were removed. S. G. 1012. Tapping; died.

No. 121, 53 years, male. Cancer of the mesentery due to metastasis, obstruction of the smaller chyle vessels; 600 c.c. of chylous fluid were removed. Section; died.

No. 122. Gastric carcinoma with thrombosis of the venous system and resulting in obstruction to the thoracic duct with an effusion of chylous fluid into the pleura. Died.

No. 123. Carcinoma involving the thoracic duct, which was probably compressed in the mass. There was a chylous effusion into both the peritoneal and pleural cavities. Died.

No. 124, 5 weeks, male. Lymphangioma of the peritoneum; 750 c.c. of chylous fluid were removed. The specific gravity of the fluid was 1007, and it contained 4.756 per cent. of fats. Tapping; recovery.

No. 125, 35 years, male. Chylous ascites with chyluria. The patient had lived in South America and filaria were found in blood, but not in the chylous fluid. Tapping; recovery.

No. 126, 16 years, female. Chronic nephritis, with marasmus and thrombosis of the innominate veins. There was a large chylous effusion into the peritoneum. Its specific gravity was 1005. Two tappings; died.

No. 127, 11 years, male. Tuberculosis of the peritoneum and obstruction of the lacteals. Thoracic duct patulous. The fluid was walled off in many small compartments by firm and plastic adhesions. Omentum shrunken and its lacteals tortuous. Chylous effusion *1,200 c.c. at autopsy. S. G. 1014.* Medicines; died.

No. 128, 33 years, female. Puerperal sepsis with pelvic peritonitis. One and one-half pints of chylous fluid were removed from the peritoneal cavity. Specific gravity of the fluid 1014. Puncture through the vaginal wall; recovery.

Radioactive Wool.—Cotton-wool which has been submitted to the action of radium emanation is convenient for easy distribution over the body; it may be packed in hermetically sealed jars, as it loses radioactivity very slowly, and can be sent to any distance desired. From a few milligrams of radium, according to the *Medical Age*, a large quantity of wool may be prepared, and thus widely extend the use of a small amount of radium, whose cost is so great as to interfere with its widespread use. The effects of the radium emanation and of the direct action of the radium are in all probability the same. Radioactive wool, therefore, may become a stock pharmaceutic preparation.

THE ENVIRONMENT AND VISUAL REQUIREMENTS OF RAILWAY ENGINEMEN AND FIREMEN.

PERSONAL OBSERVATIONS FROM AN ENGINE CAB.*

NELSON MILES BLACK, M.D.
MILWAUKEE, WIS.

Of the total railroad mileage of the United States (approximately 302,000 miles), nearly 13 per cent., or 39,263.9 miles,[1] are using a block system of signaling for the protection and spacing of trains. This system of controlling trains requires, in the daytime, the determination of the position of a semaphore arm, about 4 feet long by 6 inches wide, or distinguishing the color of a disc about 17 inches in diameter, displayed on a pole about 26 feet high. At night the color of a 6-inch lens, lighted by a kerosene lamp, must be observed. These must be determined by the enginemen at sufficient distance in which to control their trains. Mr. R. Quayle, superintendent of motive power of the Chicago & Northwestern Railway, kindly furnishes the following data, which are the result of some recent experiments in controlling fast trains:

> With the ordinary brake, 70 pounds train-line pressure, a six-car train running 70 miles an hour can be stopped inside of 2,000 feet, approximately 1,900 feet, and when the high-speed brake, 110 pounds train-line pressure, is used on the same train and running at the same speed, the train can be stopped in 1,450 feet.

It will be seen that a signal must be read at not much less than one-half mile (2,640 feet), as a few seconds are necessary for the engineman to shut off his steam and apply his air, and in each one of these seconds a train, traveling 70 miles an hour, is covering 88 feet.

There is no question that next to the necessary practical knowledge of his engine, the vision and color perception of enginemen is the most important.

The latest obtainable statistics of railroad accidents (June 30, 1902, from the report of the Interstate Commerce Committee),[2] gives the terrific number of 8,588 killed and 64,662 injured from June 30, 1901, to June 30, 1902. Collisions and a large percentage of derailments are the only class of accidents in which defective vision or color perception can be regarded as a causative factor. Collisions caused 617 deaths and 5,350 injuries, derailments caused 293 deaths and 2,504 injuries. There seems to be no classification of accidents up to date which gives those caused by defective vision or color perception.

During 1902, in Illinois, there were 138 derailments due to trains running against signals.

None of the writers on the visual requirements of trainmen have given the subject of their *environment* much, if any, consideration. Dr. H. B. Young's paper,[3] "The Visual Requirements of Trainmen, Based on Personal Observations from an Engine Cab," was the first to do this, and suggested to me that deductions from a large series of observations made in the same environment and under the same conditions as enginemen work, would be of material value. I was governed in these experiments by the standards required in the reports adopted by the American Medical Association, the American Ophthalmological Society, and the American Academy of Railway Surgeons. A careful examination of my eyes resulted in vision with either eye (without glasses) 6/V (20/15), perfect color vision and muscular balance, refraction O. D. +.50 cyl. ax. 85°, O. S. +.62 cyl. ax. 135°.

DAY SIGNALS.

Trainmen and enginemen on steam roads are governed in their manipulation or movement of trains very largely by signals.

Railway signaling is of two kinds, visible and audible. This paper will deal only with visible signals.

Visible signals are divided into two grand classes, fixed and moving. This division also applies to night as well as day signals. It is quite generally accepted that red designates danger, green or yellow caution, and white or green clear. This scheme usually applies to flags (Fig. 1), switch targets (Fig. 2), gates (Fig. 3) and bars, but color in block, interlocking and signal department work does not indicate much in day signaling, as practically all signals are position signals. This, however, makes the test for color vision none the less important.[4]

It is to be remembered that the function of all fixed signals, whether called block signals or by some other name, is to inform the engineman whether or not he may proceed beyond the signal, or on what conditions he may proceed, and to convey the information some seconds before it will have to be acted on. This last is a vital feature, for the essential difference between driving a horse in the street and driving a locomotive, the difference which makes costly signals necessary, is that the engine driver, controlling a heavy body moving at high speed, must have ample preliminary notice of any requirement to stop.

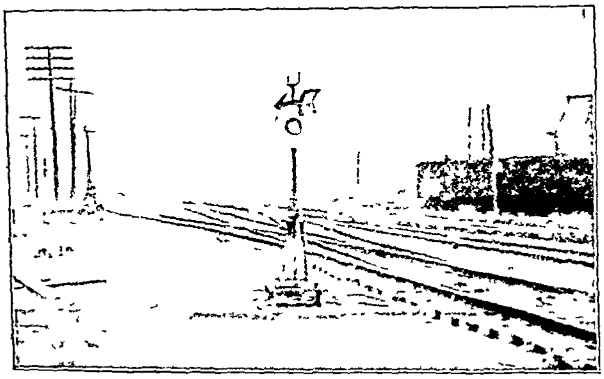

Fig. 2.—High switch target, Kansas City yards.

Day-fixed signals are whistling posts, road-crossing signs, flags, switch targets, train order signals, gates or bars, interlocking and block signals (Figs 4 and 5).

If the speed of the trains is much increased, as the experiments in Germany with the electrical road indicate, and a maximum of 100 to 120 miles an hour maintained, the semaphores will have to be much larger, to enable them to be seen at a sufficient distance to control the train, or some automatic arrangement used which will cut off the current for an obstruction signal.

NIGHT SIGNALS.

As the trainmen are almost entirely dependent on signals at night for information as to track obstructions, location, warnings and means of communication, this is the most important part of railway signaling—it should be the simplest, the surest, and should have the contrasts most marked. The colors used are red, white, green, and on some roads yellow.

The fixed night signals are white, red, yellow and green lamps or lanterns, with purple or dark blue in use for back lights at interlocking plants. Red and green fuzees are used for emergency signals and to indicate track conditions.

In all night signaling, while the color is the main indication, the location of the lights has something to do with determining the meaning of signals, i. e., a red above a white or green will indicate one thing, and a white or green above a red another; hence the necessity for perfect color perception. Yellow is used as a caution signal on roads where green is used for clear. Its usefulness is in case a glass should break in any signal, a white light would show when it should be yellow, red or green, and indicates that something is wrong.

The arrangement of night signals, green and red on the home signal and green and yellow on the distant, has been the practice on the New York, New Haven & Hartford for about two years, and is being adopted by a few other roads. The use of green for "Proceed" relieves the enginemen of the risk of taking a street or house light for an all-right signal. Yellow lights, to be always quickly distinguished from common "white" lights, must be so dark as to look a little like red, but this likeness is not found to cause any difficulty in practice. Even if a distant signal were to be taken for a stop signal, no harm would ensue.[4]

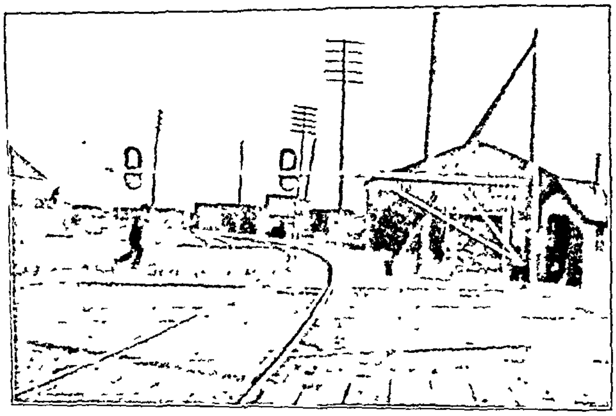

Fig. 3.—Crossing gate, C. & G. W. R. R.

Night-motion signals are made with white, red, yellow and green lanterns swung by hand.

There has been some effort made to get a position signal for night, but so far nothing satisfactory has been accomplished.

TRAIN ORDERS.

The fact that the time schedule of trains must be so closely followed and telegraphic permission must be obtained by enginemen and conductors to proceed if their train is late, also adds greatly to the safety of trains running under the block system.

Train orders written on different colored paper, which designates the class, is in use on some roads. For instance, the Baltimore & Ohio uses yellow for general, green for caution and white for clearance orders.

Some roads use signals which stand normally in the clear position, while others use those which are normally in the danger position. Both have their advantages and disadvantages; normally at danger position would seem the safest, however.

THE ENGINEER.

"A few years ago the profession of engine driver was one which did not require such an amount of skill as is necessary to-day. Men who entered the ranks were brought up from the brakemen and firemen class and were rather men of superior intelligence. To-day, however, all is changed, for the reason that a higher grade of ability is demanded and high speed locomotives are infinitely intricate and demand a higher grade of scientific knowledge."

CONDITIONS ABOUT ENGINE AND RAILROAD YARDS.

Conditions existing about an engine, such as the escape of steam when an injector is used, when the whistle is blown, from leaking valves or connections, from the poorly packed piston rods of air pumps, cylinders and steam chests, will often completely envelope the engine and cab (Fig. 13). Steam and soot from the smokestack is often blown back against the cab windows, covering them with steam and dirt and making it next to impossible to see through them, to say nothing of obtaining a view of anything through the condensed steam and smoke. This is especially true in passing under the viaducts or bridges entering the railroad yards of large cities, where there are many moving engines and trains, and signals must be closely watched for (Fig. 14). In freezing weather the escaping steam is especially bad, *as the windows are coated with ice, and vision* through them is out of the question. The escape of steam inside the cab in cold weather often coats the side windows with frost and ice, but rarely the front ones, as the rush of cold air against them while in motion keeps them clear. Double glass is also used, with an air space between, which prevents their freezing. The dust raised by passing trains often coats the windows, especially if they are damp from escaping steam; the engineman's position, being on the right side, escapes most of this, however, on roads which run their trains right-handed on double tracks. The cloud raised from ploughing through snow drifts shuts off all vision for the time. Some considerable complaint is made of the drivers throwing mud and dirt on the front windows in moist weather.

THE FIREMAN.

The glare from the furnace door when the engine is stoked makes the reading of signals much more difficult. There is an iron shield above the furnace door on the engineman's side, which protects him somewhat. Many enginemen have their seat curtained off to relieve them of this glare. After looking into this glow from the position of a fireman during the time required to shovel in five or six shovels of coal, it is an utter impossibility for a novice to read a signal. There was a black scotoma before my eyes, the size of the furnace door, for fully ten minutes, and I could distinguish nothing except eccentrically. Firemen have told me they could not even see their steam gauge for several minutes after a stoking, and when one takes into consideration that from three to ten tons of coal are handled in a two to five hours' run, there is not much let up from looking into the fire-box, and when this is done daily for five or six years, or even longer, before a fireman can expect to become an engineman, it must be a good pair of eyes that can stand it and pass the required standard examination for promotion, without a rest or change.

Again quoting from Mr. Quayle's letter:

> I think you are correct in this matter—that is, it is quite difficult for a new fireman to do this, *and it would affect* one's eyes who is not accustomed to it, but the firemen who are accustomed to this kind of work have a method of shielding their eyes by the manner in which they guard them with their eyelids, and closing the eyes. They can look into a fire and distinguish things you and I could not do. The same is true of a blacksmith. Take a blacksmith and let him have a piece of iron in the fire, and when it is pretty nearly up to the temperature *of the fire, the blacksmith,* with his trained eye, can see the difference there is between the color of the iron and the color of the surrounding body of fire, while the eyes of the novice would be so affected by the brightness of the light that he would not be able to see anything in the fire. This is true with a locomotive fireman. When he gets accustomed to it, he can use his eyes advantageously to the light conditions before him.

HEADLIGHTS.

The divergent rays from the headlight make it more difficult to read signals if there is fog, snow or mist in the air; with the electric headlights, while they are of the greatest advantage in all other ways, this is much more aggravated, an immense disc of reflecting and refracting particles is directly before one, and it is almost impossible to distinguish signals through it. If these headlights were built on the same principle as the searchlights of the Navy, so that they would throw parallel rays and could be deflected to strike the track at say 100 yards' distance in front of the engine, they would be greatly improved. This effect was obtained for Dr. Young and myself on the Burlington Road by Mr. J. A. Carney,[7] the master mechanic of the Burlington Division, by making an extension to cut off the divergent rays and stopping the light down with a diaphragm. An 18-inch extension with the light stopped down to a pencil about 9 inches in diameter made a perfect light.

Mr. Mark A. Ross,[8] general manager of the Pyle-National Electric Headlight Co., in discussing Mr. Carney's paper before the Western Railway Club, said:

> I have a great many letters, too, from engineers who are *running the electric headlights, who state that they* strain their eyes more in running an engine with an oil headlight in one night than they do with the electric headlight, for the reason that they are always gazing fixedly ahead, trying to *find or pick up something, and with the electric* headlight they can sit back in the cab; they do not have to put their heads outside of the cab, and they can see anything just as they can in the daytime.

It is impossible to estimate distances accurately behind an electric headlight, or to tell how far off an oncoming train lighted with one is.

The effect on the eyes of looking into an approaching electric headlight on double tracks is very much the same as looking into a searchlight, but it is unnecessary for enginemen to look directly into the source of light.

MOTION OF THE ENGINE.

The constant jarring, swaying and rolling of an engine traveling at a high rate of speed, is another factor in making signal reading difficult.

The constant supervision of an engine takes no small part of an engineman's time and attention, and his duties are far more than sitting on the seat and watching for signals. This is especially true when there is any trouble with the various mechanisms under his care

ATMOSPHERIC CONDITIONS.

Certain atmospheric conditions are not only a sourc of great annoyance in reading signals, but often com-

---

7. Carney, J. A.: The Electric Headlight, West. Railway Cl May 17, 1904.

8. Ross, Mark A.: The Electric Headlight, West. Railway Cl May 17, 1904.

pletely obscure them at a distance sufficient to control a train. Fog, snow, mist and rain take precedence in the order given, and when it is necessary for better vision to have the head out of the cab window, the impingement of the fine particles of snow, mist or rain against the eyes blinds one almost instantly. The force of the wind traveling at a high rate of speed causes the tears to flow and blurs the vision after a very short exposure.

Night signals are seen at a greater distance in these atmospheric conditions than day. The foreground and background of day signals make a great difference with their being easily seen. A sky background is the ideal (Fig. 15); the kind of day does not seem to make much difference. Signals displayed on roads running through mountainous country, and especially where there are many curves in valleys, are very hard to distinguish from the elevated positions on either side (Fig. 16). Woods stripped of their leaves or in full foliage, the proximity to buildings and bridges, all tend to make the position signals less distinct, while the cross-bars of telegraph poles are very confusing (Figs. 17, 18, 19, 20). Undoubtedly night signals are much easier read, as the contrast is so much greater, but as to their being seen any farther, or so far, atmospheric conditions being the same, is questionable.

The reflection from snow, from a body of water, from the solid green of foliage, running toward the sun when near the horizon, the shimmer in the atmosphere on hot summer days, all are features which add much to the difficulty of seeing signals.

Thus it will be seen from the factors enumerated above requiring good vision and those tending to interfere with it, the best known standard of binocular single vision and color perception is none too good, and not only must a man have this, but it must be "quick vision" (referred to by Dr. A. H. Andrews[9] and Dr. J. E. Minney[10]), for he may for an instant be able to see through some break in the interfering media, and must be able to read his signal in that instant.

There seems to be no means of overcoming the interference with vision by escaping steam. An engine may come from the roundhouse in perfect condition, but when partly through its run something occurs which allows a leak, and the enginemen have this to contend with.

EXPERIMENTS WITH LENSES.

Lenses of various colors were experimented with in looking into the fire-box from the fireman's position, and then trying to read day and night signals. The night signals were harder to see because of the glare being more intense in the surrounding darkness, the daylight relieving part of its intensity. Smoke lenses of the deeper shades allowed one to look into the fire-box without producing a scotoma before the eyes, but distinguishing signals with them and seeing the various mechanism about the cab distinctly, is out of the question; the color signals are made very indistinct. Green lenses are very good, but they blot out the red lights entirely, making one blind to red. Red lenses make the green appear dirty white, producing green blindness. Blue lenses do not cut out enough of the bright rays, and one is troubled with scotoma. A light amber lens, such as referred to in the German abstracts in the *Annals of Ophthalmology*[11] and by Dr. H. H. Seabrook,[12] as having been tried in the German army for target practice, gave a perfect result. I could look into the fire-box of the large type engines, see all parts distinctly, relieved of the blinding glare, see about the cab perfectly, climb on the seat with no spot before my eyes, and the signal lights maintain their clear definition of color, white being tinged a slight yellowish. The green light can not be seen at so great a distance as with the naked eye, but red and white can be seen an equal distance and with equal distinctness. The effect produced by watching the lights with green lenses before the eyes was rather weird, as red lights were practically blotted out, and on removing the lenses flash into view in a startling manner; the white and green lights were not affected. With red lenses the green lights were observed as white coming through dirty glass; the white lights were tinged with a faint red.

EFFECT OF THE FURNACE GLARE ON THE EYES.

As to the effect on the eyes of looking directly into the white heat of a furnace, various authorities disagree. Snell[13] says:

> There is, I think, no definite evidence that men exposed to the heat and glare of the furnaces or from the molten metal suffer materially in their eyesight, though some assert that disease of the background of the eye is occasioned in some instances.

Fuchs mentions retinitis due to a dazzling produced by gazing at sun and electric arc lights.

The following questions were sent to a number of ophthalmic surgeons who come more or less in contact with men working under these conditions:

> 1. Have you found among furnacemen, glassblowers, railroad firemen or iron mill workers ocular conditions the result of looking into the glare of furnaces, which have caused any reduction in vision? 2. If so, was the injury permanent?

Many answers were negative. A few replies from conservative men are quoted:

Dr. Ledbetter, Birmingham, Ala., reports two or three cases of chorioidal irritation among brass furnace workers.

Dr. Edward Jackson says:

> I have seen early opacity of the lens in a glassblower and several cases of inflammation and subsequent atrophy of the chorioid in blacksmiths and rolling mill workers which caused impairment of vision. In all cases the injury seemed to be permanent and directly connected with the exposure to heat.

Dr. de Schweinitz, after the examination of puddlers for incipient cataract, concluded that:

> These puddlers are apt to show a good deal of low-grade disturbance of the chorioid, the condition which is sometimes vaguely called congestion of the chorioid, the "ripe peach chorioid" of Risley's phraseology, and it seems possible to tell by ophthalmoscopic examination whether a man was a right-handed or a left-handed puddler; in other words, that eye which was more directly exposed to the glare from the furnace was the one more apt to show the condition to which I have referred.

Dr. Posey, after examination of several hundred glassblowers and men working about the furnaces in glass establishments, says:

> I am convinced that working over furnaces does produce cataracts, for I have found opacities of the lens at an age far earlier in men engaged in this work than could be accounted for by senility. In looking over my ophthalmoscopic findings

13. Snell, Simeon: Dangerous Trades.

of the cases, I noted that I thought the chorioids were congested and the optic nerves grayer than they should be in many instances. Whether the cataracts are due to the chorioidal changes or whether they are due to the heat or light emanating from the furnaces or from the action of some rays whose existence is unknown to us at present, I can not say.

Dr. Casey A. Wood reports a case from an electric welding furnace, and says:

> In answer to your circular note, I know that I have had a number of cases of injury to the eye from looking into furnaces without the protection of glasses. In one case the injury lasted at least a year, and, so far as my information goes, was permanent.

Dr. Charles A. Oliver said:

> I have had a number of cases; not only uveal tract and retinal disturbance, but with both associated and consequent lenticular swelling and opacification. The interesting point of my findings has been that the left eye was the one which was either primarily or alone affected in right-handed men, this eye, by reason of the right arm being the governing one, being that which was situated near the fire. The injury was permanent, but never absolute, as proved by studying the eyegrounds after extraction of cataract.

Dr. Minnehan, Topeka, reports many complaints from firemen, but no permanent trouble.

Dr. Chas. H. Williams has never seen a case, but remarks: "It is easy to believe such work would aggravate such existing conditions," and Dr. Burry's[14] recent paper, "Electrical Ophthalmias," mentions several from electric welding. The reports show no permanent injury resulting from electric flashing.

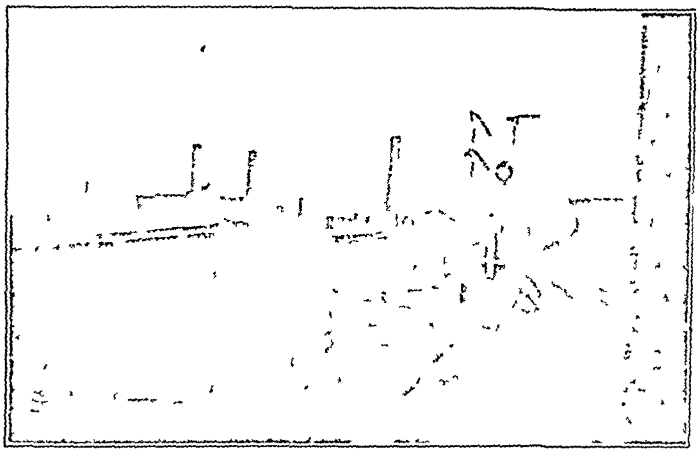

Fig. 4.—Combination disc and semaphore block, C. & N. W. R. R.

A number of firemen have volunteered the information that they had passed their entrance examination all right, but when they were re-examined after four or five years' service their left eye was not so good as the right, which is the one next to the fire-box in stoking.

MECHANICAL PROTECTION OF THE EYES.

Protection of some kind is the only method of overcoming the effect produced by the impact of snow, mist, rain and wind against the eye, and all sorts of devices are resorted to. Fully 90 per cent. of the men questioned admitted they carried some form of a protection glass for such an emergency. With lenses before my eyes I found no difficulty in facing the worst storms; the glasses did not become dimmed enough to prevent sufficient vision to read signals at any distance they could be made out with prevailing weather conditions, and the condition of the eyes was infinitely better. The larger the lenses the more perfect the protection The question of fogging, as Dr. Young[3] says, "may be dismissed if we only stop to consider that fogging only occurs when going from a cold air into a warm one," and within five seconds after contact with cold air the lenses are clear again. This point, however, is one small factor against the use of glasses by trainmen, as the engineer is unable to see distinctly about his cab for the few moments his glasses are fogged, after contact with cold, but he is equally unable to see for the same length of time as a result of coming in contact with snow, rain and wind with the naked eye. The lenses also protect the eyes from the flying coal dust in the cab.

The reflection from snow, from a body of water, the sun near the horizon and the shimmer on hot days was best overcome with the amber lenses.

CARE OF THE LAMPS IN NIGHT SIGNALING.

A very great deal depends, in night signaling, on the care taken of the lamps used, and the lenses in the spectacle frame of the semaphore arm must be kept clean. A lamp not properly trimmed or turned too high will smoke its lenses, and as a consequence the signal is dim or almost invisible. Under such conditions enginemen with defective color perception or a tendency toward color confusion can not distinguish between red, green or white; even with normal color perception the signal can not be seen at sufficient distance to control a train. The difference in the care taken of the lamps is very marked in going over 40 or 50 miles of road

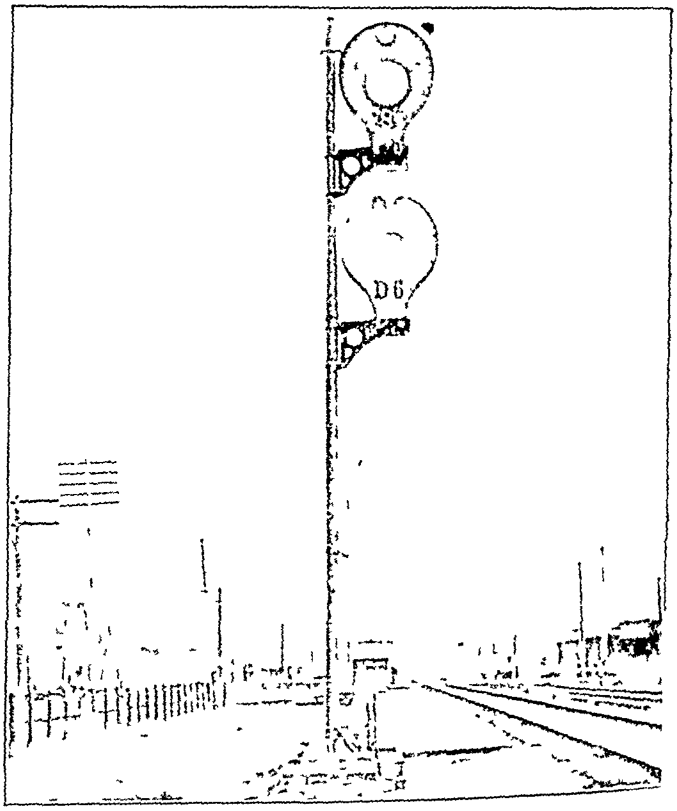

Fig 5—Disc block signal, C. & N. W. R. R.

With 20/20 (6/VI) V., under good atmospheric conditions, with good backgrounds (Fig. 14), semaphore could be distinguished at 2 to 3 miles. With night signals, under the same conditions, the white could be seen at 1 to 2 miles, the red at 1 to 1½ miles, and the green and yellow at ½ to 1 mile. When I became familiar with the location, position, and background of a signal, I could distinguish it at a greater distance, showing that the *enginemen*, knowing just where to look for the signals, can distinguish them much more quickly and at a greater distance than a novice with equally good vision.

---

14. Burry, Dr. James: Electrical Ophthalmia, Chicago Medical Recorder, March, 1904.

With +1.00 D. before each eye, my vision was reduced to 20/40 (6/XII) with the Snellen test type with which I could make out day-position signals at about 2,800 feet, night signals at about 3,000 feet. Plus 1.50 gave me 20/80 (6/XXIV) vision. With these I could not make out a signal until within 200 to 500 feet.

Dr. Young[3] states:

> The lamp signals stand out better with 20/40 than with 20/20. This is explained when one considers that with 20/20 the effulgent rays can be made out. These effulgent rays give a twinkling unsteady effect, which is still farther accentuated by the jolting of the engine. With 20/40 these effulgent rays are blotted out and the lamps stand out as illuminated discs.

This was also my experience. At the much-lessened distance I could make out the lights with 20/40 (6/XII) V.; but I could make them out much more clearly and at a much greater distance with 20/20 (6/VI) V., as cited above, and again, if there were a number of lights displayed, as are usually seen in railroad yards, the proximity of these illuminated discs were very confusing.

MEDICAL REPORTS REGARDING THE STANDARD OF VISION.

There are at present four reports as to the standard of vision and hearing required by trainmen, which have been adopted by four representative medical societies of the United States, i. e., Section on Ophthalmology of the American Medical Association, the House of Delegates of the American Medical Association, the American Ophthalmological Society, and the American Academy of Railway Surgeons. There is a fifth report, which I have been unable to obtain so far, adopted by the American Railway Association; the work of the committee has not been completed.

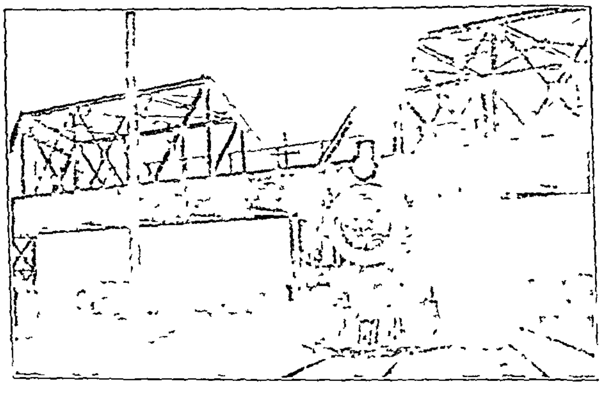

Fig 13.—Conditions about engine interfering with vision of signals.

These reports are all the result of careful and painstaking work, by men who have devoted a great deal of time to the subject. Dr William Thomson[15] was the first in the United States to inaugurate a system of practical examination of railway employes, and in 1881 this was adopted by the Pennsylvania Railroad Company. All here are familiar with the good work done by Dr. Frank Allport[16] and Dr. Chas. H. Williams.[17]

In 1901 the committee appointed three years previously by the Section on Ophthalmology[18] of the American Medical Association made their report, which was adopted by that Section. The following year the House of Delegates[19] adopted a somewhat modified report. The American Ophthalmological Society[20] report was adopted in 1901. The report of the American Academy of Railway Surgeons[21] was adopted in 1903.

EXAMINATION OF EMPLOYES.

Many roads are using a set of rules for the examination of their employes, modeled after some one of these reports, and it is my opinion that if what we wish to arrive at is uniformity in examinations among the various railroads, the medical organizations must have a uniform report. These reports vary but little in the essential features, and any one could well be adopted by all.

There is no reason why they can not be merged (as some railroads are trying to do at the present time) into one, and we could then have a uniform standard in practice as well as name; and it seems feasible that if four representative societies combine on one report the railroad officials will be much more willing to adopt the same. Then, as Dr. Chamberlain remarks: "We shall be working in harmony with others, and when a man comes off the C., B. & Q. to the Northern Pacific, he can not be employed if he has been discharged from the Q. road."

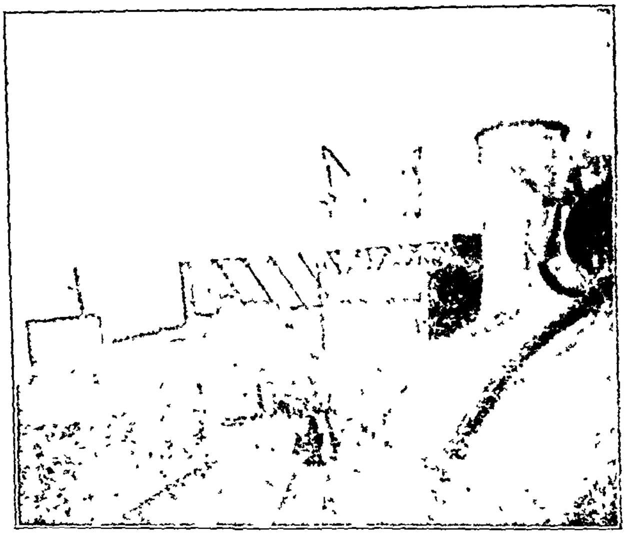

Fig 14.—Block signal with smoke background, C. & N. W. R. R.

Regarding the sections of the four reports, all agree as to the necessity of examination for vision and hearing.

In Section 2 there is a slight bone of contention, and while it must be admitted that examinations by ophthalmic surgeons would be more scientific and more nearly correct, it has been conclusively shown that examinations carried out under the instruction of an ophthalmic surgeon, by men selected by the company, who refer doubtful cases to such surgeon, have resulted in perfect satisfaction to all concerned.

[21] Report adopted by American Academy of Railway Surgeons, Uniform Standard for the Examination of Railway Employes, Transactions Amer. Acad. Railway Surgeons, 1903.

The reports all agree as to the standard of test types used. A word may be said here regarding uniformity of illumination of test type, inasmuch as uniformity is the watchword. We all know what a variation there is in the intensity of illumination of test charts, and this results in a very great difference in the grade of visual acuity obtained by different examiners. A transilluminated or self-luminous test cabinet is the only means of overcoming this difficulty. Such a one is described in the *Ophthalmic Record.*[22]

The section referring to the minimum requirements for acuteness of vision is the most important clause, and all the reports agree that 20/20 (6/VI) vision in each eye without glasses shall be required for entrance into service or promotion.

STANDARD OF REQUIREMENTS.

The standard of 20/20 (6/VI) V. for entrance into service for Class "A" is the least that should be required; but when it comes to promotion in service, there should be some concession made, for firemen who have stoked from five to eight years show, as a rule, some loss of vision, especially in the left eye, which improves, according to the records, after the change in environment. Dr. Williams[17] says:

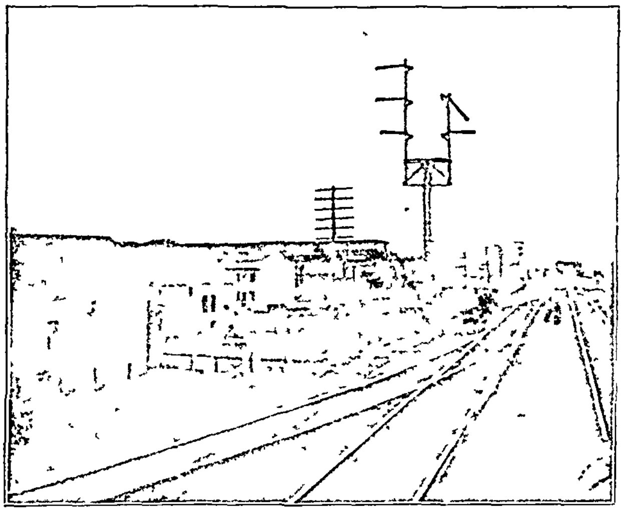

Fig. 15.—Bracket pole semaphore block, C., M. & St. P. R. R. Ideal background.

> A fireman who has worked for some six years satisfactorily as fireman comes up for promotion to engineer. He has only 20/30 vision; the rule requires 20/20, the object being that when a man first began his work as engineman or fireman you wanted to begin with a man who had normal vision. It seems to me that it is hardly fair as it works out. If he has 20/30 on re-examination you will allow him to continue to run as fireman, and if he has 20/30 on re-examination you will allow him to continue to work as engineman; then, why not allow him to be transferred from one side of the cab to the other with the same amount of vision, 20/30?

The House of Delegates' report and that of the American Ophthalmological Society require for re-examination of those in the service, "20/30 with both eyes open, without glasses," with the additional requirement that "each eye should be tested separately and the vision of each noted." Under this ruling a man with one blind eye could be retained in service, and Dr. Williams[17] brings the following argument forward in support of what he acknowledges to be a fact:

> This rule allows a man to continue running who has 20/30 of normal vision in one eye and little or none in the other. The fact of such defect is brought to the notice of the operating officer in the report of the examination, and a man with this defect would naturally be assigned to less trying runs than would be given to those with perfect sight. A standard has sometimes been recommended which provides that in this class a man must have vision of 20/30, or better, in one eye, and 20/40, or better, in the other in order to be passed as satisfactory. Suppose a man had 20/20, or normal vision, in one eye, and 20/50 in the other. This rule would reject him, which seems unfair. In such a case the man, for all practical purposes, uses only the visual impressions which he gets from his good eye, and it makes little difference to him in his work whether the poor eye has a vision of 20/50, or 20/70, or 20/40. The work he is able to do is measured by the capacity of the better eye, and he becomes so accustomed to the monocular vision that it gives him little inconvenience. It has been urged that if an engineman with only one good eye got a hot cinder in it he would be of little use. That is true; but it must be remembered that in the cab there is always a fireman with a second pair of good eyes, ready to take up the work in any such emergency until assistance can be obtained, and also, even if the engineman had two good eyes, the pain and flow of tears which would be caused by the hot cinder in one eye, would prevent a satisfactory use of the other.

In reply to this, in the first place, Dr. Williams admits that the man is not so safe a man and should be "assigned a less trying run." Further, I contend that with 20/30 in one eye, 20/40, 20/50 or even 20/70 in the other, helps the vision of the better eye. With my vision reduced to 20/40 I could read day signals perfectly at ½ mile, night signals at 4,000 feet, and with 20/80 at 500 feet and 800 feet, respectively. The fireman has about all he can attend to on a limited train without assuming an engineman's responsibility; further, there should be no excuse for using him in such an emergency, by simply changing the clause to read as it does in the other reports, or as it does in the reports from which it was evidently adopted, i. e., that of the Dutch State Railway.[23]

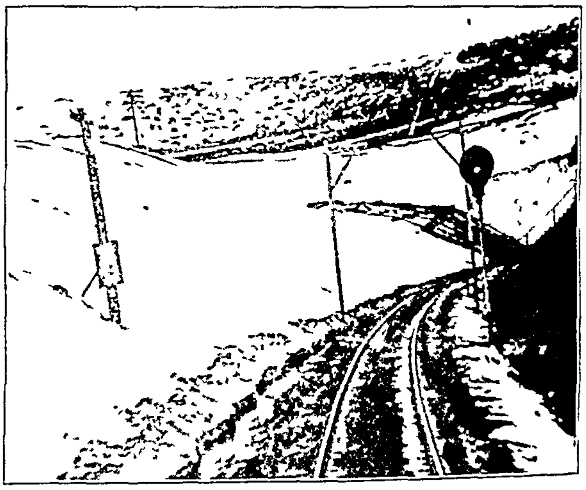

Fig. 16—Disc home signal for tunnel with bad background, U. P. R. R.

> For the post of engine driver or stoker, . . . on looking with both eyes open, visual acuteness of at least 3/4 (without glasses) . . . with each eye separately, the other eye being covered, visual acuteness of at least 1/3 (without glasses). . . .

This would fully cover the entire field of contention Dr. Allport's[24] stand against this clause is well taken:

---

[22] Black, Dr. Nelson M.: Luminous Test Cabinet, Ophth. Record, April, 1904.

[23] Transactions Amer. Ophth. Soc., 1902.

[24] Allport, Dr. Frank: Some Remarks Concerning the Ocular and Aural Requirements of Railway Employes, Railway Surgeon, December, 1903.

Under Section 5, House of Delegates' report, under the requirements for re-examinations of those in the service "belonging to Class A," it says: "The employe shall possess a vision of 20/30 with both eyes open, without glasses. Each eye should also be tested separately and the vision of each noted." This opens a wide avenue of discussion. The report of the Section on Ophthalmology concerning this same point says that "Employes enumerated in Class A shall not be retained in such positions if vision sinks below 20/30 in one eye and 20/40 in the other." In other words, a reasonable standard is required of each eye, and it seems as if this must appeal to the judgment of anyone at all familiar with such work. Would anyone in this society care to travel on a train at the rate of 50 or 60 miles an hour with an engineer wearing a glass eye? I think not; the idea is untenable, and yet this is exactly what the House of Delegates' report permits, for it says that vision must be 20/30 with both eyes open. To be sure, it also says: "Each eye should be tested separately, and the vision of each noted," but it goes no further. It does not inflict any penalty in case an engineer has one blind eye. While disposed to be most liberal with the old employes of a road, and while recognizing its advisability and almost necessity if good service and freedom from labor union complications are to be encouraged, I still can not indorse the idea of testing with both eyes open, and of ignoring the condition of a man's worst eye. The idea is evidently conceived from the action of the International Congress, which met in Amsterdam in 1879, and which in formulating rules for the ocular condition of transportation employes, under the guidance of Professor Donders, repeatedly speaks of testing with "both eyes open." This was evidently recommended, because it is well known that one eye assists the other to see, and the committee desired to treat all employes with all possible clemency, but they did not in their recommendations ignore the condition of either eye.

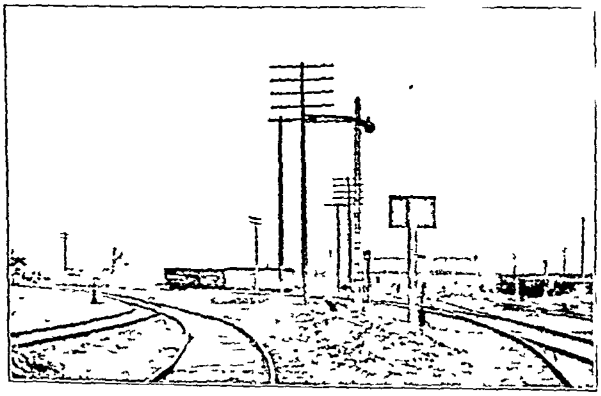

Fig 17.—Semaphores with bars of telegraph poles interfering, Kansas City yards.

Magnus and Würdemann[25] give as the minimum amount of vision for enginemen 75 per cent. of the scientific standard (6/VI), which is equal to 6/VIII, or approximately 20/XXX, "which is practically a perfect working or economic standard of vision"

Applicants for entrance into service possessing 1½ D. of hyperopia or over, should not be accepted, for the reason that they will need glasses to bring their vision up to the required standard at the age of 35 or 40.

At this point the subject of glasses must be considered, and from my experience I would heartily indorse a clause to the effect that if the vision of those examined for promotion after five years' service and those re-examined in service fell below the standard required, and such vision could be brought up to the required standard by glasses, they be promoted or retained in service. "Glasses must be worn if they are necessary to secure adequate vision." It is my unbiased opinion that protection to the eyes by lenses, more especially if needed to correct any refractive error, are of great benefit, and such opinion has been arrived at with a great deal of thought and careful study of the few objections to glasses for trainmen. The reports of Dr. J. de Lantshure[26] and Dr. J. A. Denney[27] as to the diminution of vision after long runs, I think can be easily explained. The men undoubtedly had more or less latent hyperopia, and the constant accommodative effort so tired the ciliary muscle that vision was somewhat reduced after a long run.

The color tests are of equal importance with visual acuity, and all reports agree in the use of the Holmgren wools.

The use of a lantern for a control test is a good idea, but why in the examination with the Holmgren wools is the following rule given: "No names should be mentioned in connection with any color in the above worsted tests; the tests should be based only on a comparison of colors," and with the lantern test, "have the person being examined call the names of the colors shown."

The value of the color test is to determine whether the person examined can distinguish between various shades and degrees of intensity of color, so they can be sure of a signal if its intensity is reduced by atmospheric conditions, smoky or dirty lenses, or improperly regulated illumination. It has been stated many times that men can distinguish without any hesitation between danger, caution or clear colors, displayed of varying degrees of intensity, but fall down at once if required to name the colors:

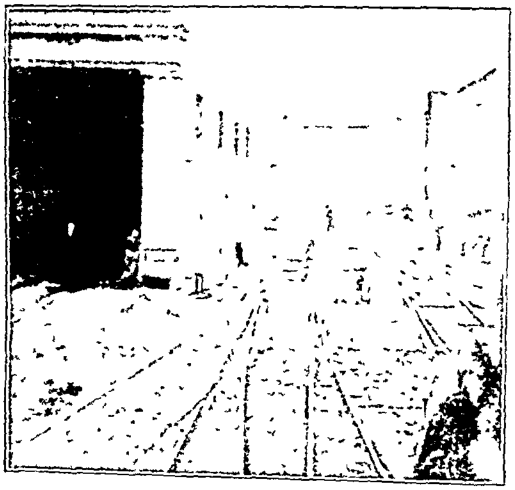

Fig. 18—Block signal with bad background, C., M. & St. P. R. R.

Again quoting Dr. Williams:[17]

> I have found personally in the last few years four cases of men who passed the worsted test without any difficulty, who picked out these colors quickly and accurately, but when they looked at a distant signal, or when they looked at the testing lantern, especially with small openings, they would often call a red light green, or a green light red; they were just as likely to mix up red and green as they were to get them right. This is due to a defect in the central portion of the retina. In such cases, when the colored object is large enough, or when it is placed near enough to the eyes, its image will extend beyond the affected parts of the retina, and its color can be at once recognized; but when the retinal image is small, as is the case with the light from a distant signal, which falls wholly within the affected area, it is easily mistaken. In order to get at the

---

[26] de Lantshure, J: Trans. Amer. Ophth. Soc, 1902.

[27] Denney, J. A.: Trans. Amer. Ophth. Soc., 1902.

fact as to whether a man is thoroughly able to recognize his signals you need both a worsted test and a lantern test, the lantern coming nearer to the actual condition of night signals, where the man has nothing except the color to guide him.

Replying to this, I do not think a person with scotoma of sufficient magnitude to pass the worsted test and fail on the lantern test would have sufficient vision to pass the required visual standard. There is no doubt the lantern test is more nearly a road test and will seem more fair to railroad men, but it should be used only as a control test, not as a substitute for the worsted test.

The sections relating to the time of re-examination are unanimous, as also are those regarding the use of liquor.

The report should be accompanied with instructions for making the various tests and the use of the apparatus required.

CONCLUSIONS.

The result of my observations has been, in brief:

1. The best known standard of visual acuity and color perception should be required of men concerned in the active operation of trains.

2. The signal systems now in vogue, while they are not perfect, are sufficiently adequate for the standard of vision required and the present speed of trains.

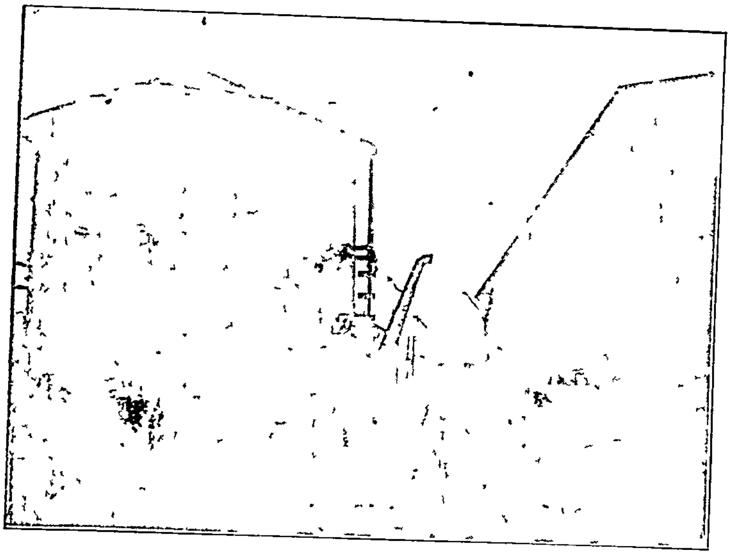

Fig. 19.—Block signal with bad foreground, C., M. & St. P. R. R.

3. Certain physical and accidental conditions about engines interfering with vision can not be overcome unless the position of the enginemen can be changed.

4. Certain atmospheric conditions interfering with vision can not be overcome; others can be mitigated or entirely relieved by the use of some form of protection to the eyes.

5. Glasses are not a hindrance to enginemen, and their use should be allowed when required to protect the eyes or to bring the vision up to required standard, but no person should be accepted into service requiring them or who will accept a plus lens of 1½ or 2 D.

6. With four reports emanating from four different sources of equal merit and standing, and all different in small details, the obtaining of perfect uniformity in examination of railway employes is out of the question, as it can not be expected that the officials of different roads will all decide on the same report.

7. Furthermore, state legislation on the subject of vision and color perception of railway employes is being seriously considered, two states, Massachusetts and Ohio, having statutes regulating this. As nearly all railroads pass through a number of states, it would be well for the societies from which these reports emanate to agree in all details, as the state laws will necessarily be based on them, and if different states have different standards, an engineman qualifying in one and not in another, with his run extending in both, would be in serious difficulty.

9,816. Sec. 1. Be it enacted by the general assent of the state of Ohio that no railroad company shall hereafter contract to employ any person in a position which requires him to distinguish form or color signals, unless such person within two years next preceding has been examined for color blindness in the distinct colors in actual use by such railroad company by some competent person employed and paid by the railroad company, and has received a certificate that he is not disqualified for such position by color blindness in the colors used by a railroad company. Every railroad company shall require such employe to be re-examined at least once within every two years at the expense of the railroad company, provided that nothing in this section shall prevent any railroad company from continuing in its employment any employe having defective sight in all cases where such defective sight can be fully remedied by the use of glasses or by other means satisfactory to the person making such examinations (As amended March 3, 1888.)

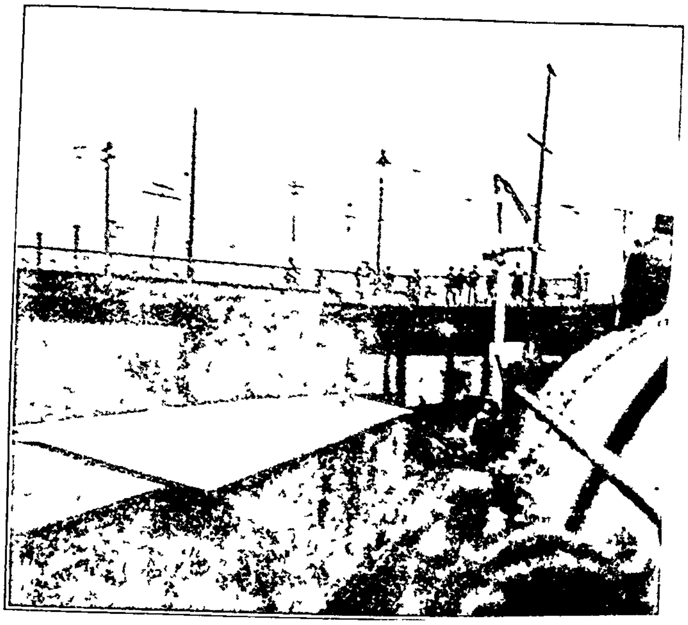

Fig. 20—Block signal with bad background, C. & N. W. R R

The law in Massachusetts is practically the same as the above.

I am greatly obliged to Dr. H. B. Young for a great many suggestions and for engine permit on a portion of the Chicago Burlington & Quincy Railway; to Dr. J. W. Chamberlain for engine permits on the Great Northern and Northern Pacific Railways; to Dr. Haldor Sneve for engine permit on the Chicago & Great Western; to Mr. A. J. Earling, president, Mr. J. N. Barr, assistant to president, Mr A. E. Manchester, superintendent motive power, and Mr. L. R. Clausen, signal engineer, of the Chicago, Milwaukee & St. Paul Railway, for engine permits and much information relating to engines and railway signaling; to Mr. W. A Gardner general manager, Mr. R. Quayle, superintendent motive power Mr. H. T. Bentley, assistant superintendent motive power, and Mr. W. E Dunham, Chicago & Northwestern Railway, for engine permit and information; to Mr. T. Lowry, president, and Mr F Pennington, general manager, the Soo Railway, for engine permit, and to Mr. A. J. Carney, master mechanic of the Chicago, Burlington & Quincy Railway, for suggestions; Mr. H L Hollister engineer Hall Signal Company, for pictures of signals and general information; Mr. Chas. Dunham, signal engineer Illinois Central Railway, for engine permit and suggestions; Mr. Mark A Ross general manager Pyle National Electric Headlight Company, for pictures and suggestions; Mr. Jos. W. Taylor, secretary Western Railway Club; Mr. F. P. Patenall, signal engineer, Mr. D D Carothers, chief engineer, and Mr. E J. Schwellenbach, train master Baltimore & Ohio Railway, for suggestions and engine permit.

DISCUSSION.

Dr. C. H. Williams, Boston—Dr. Black comes to very much the same conclusions as have been arrived at before In some of the smaller points he differs a little. As to the last thing he mentioned, in regard to legislation, it seems to me there is little use in trying to do anything in that way. The next legislature can repeal the laws made by the former one. That was done in Connecticut, and that is likely to be the fate of any legislation on the subject. In Massachusetts and Ohio the law practically amounts to nothing. In Alabama there is a little better law, but even that does not specify how the examination shall be made. In regard to the question of the lantern as a substitute for the worsted test, I have never advised it as a substitute, but simply as a supplementary test. I had a man who picked out the worsteds in the Thompson and Holmgren sets, but who in the lantern test called red green oftener than he called it red. He used tobacco to excess and had a small central scotoma for red and green, which was not large enough to cover all the retinal image of the worsteds, but the light from a distant signal came entirely within the scotoma. Men entering the service should come up to a high standard. If you have a lot of men coming into the service without any examination, and later require examinations, some of the men fail to pass, and there is trouble; but if a proper examination had been made of those men when they applied for work most of them would not have been accepted. For the post of engine driver or stoker, on looking with both eyes open, visual acuteness of at least three-fourths, without glasses; h each eye separately, the other being covered, visual acute- s of at least one-third, without glasses. This is the re- rement of the Dutch railways for re-examination. The re- rement for candidates entering the service is much more ere.

)r. J. H. Claiborne, New York City—I have never done any rk particularly along the line Dr. Black has outlined, but ny years ago there was a commission which met in Washing- ı to determine means for preventing disasters at sea, and on ıt occasion I suggested the idea of eliminating red and green tirely from the lighting of ships. I endeavored to find out ıen the system of red and green lights had been instituted. I ggested that on the starboard side a parallelogram of the ape of a star or diamond be placed, and on the other side a fferent figure, in white lights. That commission went out of ssion after having done nothing except to change the depth the water line. My paper was read and commented on and en laid aside. I have never suggested its use for railways. ıe difficulty lies in seeing the red and green colors under cer- in conditions. If we could use white light with geometrical gures, or blue, which is a rare color, it would simplify mat- rs to some extent. There should be three men on a cab— ıe to drive, one to stoke, and a third to be on watch all the me.

Dr. W. E. Lambert, New York City—There is one point not articularly emphasized, and that is the importance of having ll the employes examined by competent ophthalmologists. he method in use by most of the roads of having the man assed on by one of their own employes is not sufficient. There s no system perhaps more particular than the Pennsylvania, nd yet there came under my observation within the last year wo men who had been employed by that road who had been assed by their examiners, and who had left to go to another oad, in both of whom there was distinct color blindness. These nen should be examined by ophthalmologists. It is very diffi- ult to lay down a standard. The intelligent ophthalmologist hould be able to decide that point. There are many cases where men with 20/30 or even 20/40 vision, when due to a slight astigmatism, might be accepted. It is the cause of the poor vision which is of importance. As to the lantern, I have only found one case which showed any color blindness with it that had not been discovered by the wool tests, and that was where it was due to a central color scotoma, and in that respect the lantern test is of value.

Dr. John S. Kirkendall, Ithaca, N. Y.—There is one thing which has been omitted in this most interesting paper of Dr. Black—lack of education on the part of railroad employes as to colors. I have tried men with the wool test, and they could select the colors, but with the lantern test they failed. Failure to pass is a serious thing for these workingmen; very often a little instruction in the names of colors means a great deal. Recently I had three faithful employes fail with the lantern test. I sent them home to return in four weeks, and in the meantime told them to take some lessons. They all returned and passed a perfect examination.

Dr. H. V. Würdemann, Milwaukee—As to the points of difference between the committees, I am glad that Dr. Black and Dr. Williams have reconciled the differences that existed as to the examination of color vision. I defy any one to find a person defective so far as central scotomata and visual acuity are concerned where examination with both the woolens and Snellen tests will not reveal the defect. As Dr. Williams has allowed, I think the lantern should be a supplementary test. There are a few cases where I am convinced that the final test should be the use to which they are to put their eyes, i. e., as our final test in refraction is the experience of the patient with the glasses; so in some of our doubtful railroad cases it is necessary to examine the man on the train. Either the superintendent or one of the employes can perform that duty. If he can pass that test he is a safe man. As to legislation, I think we should have the same standard for all the states of the Union.

Dr. F. C. Todd, Minneapolis—There is one point which has not been mentioned, i. e., the possible presence of diplopia. I was consulted several years ago by an engineer who had been examined by one of the regular lay railway examiners, stating that he had discovered that at times he saw double, and that it was confusing, as he could not tell whether a signal was meant for his track or not, and could not tell on which track another train might be running. He had no fear of passing the examination, because he had perfect color vision and visual acuity of 20/20. Such cases, I presume, are rare, but it would seem that they would not be discovered by the ordinary tests made by the railway employes, and these men should certainly be retired or suspended until the diplopia is corrected.

Dr. C. F. Clark, Columbus, Ohio—These cases come to the oculist finally for examination. We have found it valuable on the Pennsylvania system to make a comparative light sense test. Dr. Rogers, I think, first instituted the plan. It is found that, irrespective of scotoma, some men have defective light sense, although with good visual acuity. Put them in a dark room at long distance, have an observer at the side of the patient to check the test, and allow them to count fingers. This method is of great value as bringing out a defective light sense that is often surprising. Such a defect is sometimes due to tobacco poisoning or to some nerve lesion.

Dr. Nelson M. Black—The question of legislation as to amount of vision and color perception required of trainmen was brought to my notice by railroad men and is something that is worrying them considerably. Regarding the lantern test for color perception, the men being examined should be required to tell whether the color shown indicates caution, danger or safety. This would be far better than naming the colors, as so many men are ignorant of the names of colors, especially the shades, and make all sorts of mistakes in attempting to name them. In examining men for the Army at the beginning of the Spanish-American War, all I had to use for color testing was paint samples, and pointing to well-defined shades, requested them to name the colors; many could not do so. When asked if there was anything a certain color resembled, as, for instance, green, they would answer readily that it was the color of grass, etc. Several superintendents have informed me that they have taken men over the roads who have failed to pass the color tests, particularly on re-examination, and found in every instance that, while the men could not pass the lantern color tests in the office, they made no mistake on the road as to what the color indicated. A high standard of vision for entrance must be required. The lessened standard for re-examination is made more for the old men, enginemen and trainmen, who came into the service without passing any examination or before examinations were required, and so the requirements must be made less than otherwise. The idea is to get men as nearly perfect as possible into service now, and later on the standard for re-examination may be raised.

Dr. Claiborne referred to the use of white lights; the majority of roads object to the use of white light in signaling entirely, as it is so easily mistaken for the lights illuminating the cities and towns the roads run through. They are now using yellow to some extent as a caution color, with green as clear. The use of blue lenses is out of the question with the kerosene lamps used to illuminate them, as they can not be distinguished at sufficient distance to be of use as a signal. With my vision reduced to one-half of normal, I could make out signals at one-half mile, and so I think enginemen with 20/40 vision should be retained in service, even if with but 20/40 in both eyes, and especially if a clause be inserted to take them from the more trying runs and give them service about the yards, where such a high standard of vision is not necessary.

THE SANATORIUM FOR INCIPIENT PULMONARY TUBERCULOSIS.

ITS AIMS, METHODS AND RESULTS.

FREDERICK L. HILLS, M.D.
First Assistant Physician New Hampshire State Hospital.
CONCORD, N. H.

HOME AND SANATORIUM TREATMENT.

The open-air treatment of tuberculosis is to-day an established fact. Its curative value is proven beyond cavil. It is not an experiment. It does not mean, however, that the patient is to be restored simply by a few weeks' or months' sojourn in a "lodge in some vast wilderness" or out-of-door life at a fashionable mountain resort or a tent life in his own back yard under the simple guidance of his own sweet will. It means rather a systematic regulated life under rigid discipline and routine. It means the constant watchfulness of every symptom, not by the patient himself, for this leads to introspection and consequent defeat, but by a well-trained nurse and a physician of experience. It means expense to the individual in time, in patience and in money. To the rich or the well-to-do this may be possible in his own house. For even the most favorably circumstanced, however, the proper régime at home is difficult if not well-nigh impossible. The family or friends of the patient can not give intelligent co-operation, and in laudable attempts to help will hinder advance by over-indulgence. Well-nourished, incipient cases with fair bodily strength do not impress their friends or themselves as invalids and are easily tempted to over-exercise, injurious amusements or other undue expenditure of energy, seriously handicapping the best efforts of even a thoroughly trained medical attendant.

Even when private grounds and houses can be adapted to the requirements of an out-of-door life the patient will often find himself unable to make full use of them because of the exaggerated impression such living makes on his neighbors and friends, much to his embarrassment, and it may be to the serious detriment to his present or future business interests. We live too close to the radiator in our northern homes to give intelligent appreciation to the man sitting on his veranda wrapped in rugs and reading his morning paper with the mercury at zero, even though later in the day we meet that man in office or store. Such things can not fail to provoke unwarranted remarks until we have been more liberally educated as to the value of oxygen and good red blood.

In such sanatoria as exist to-day the patient can find most congenial surroundings and agreeable companionship among persons of his own social class. He readily enters into the routine to the observation of which he is helped by the example of his fellows. He is stimulated by the spirit of hope which is everywhere manifest, and by the sight of others as ill or worse than himself steadily improving and returning to their work restored.

To be sure, all do not get well; some he sees slowly decline, occasionally some one dies, but these are exceptional cases and in spite of them the spirit of hopefulness is dominant and an inspiration to each to put forth his best efforts toward recovery. The medical supervision is here such as it is not possible to provide in the patient's home. A hospital with properly trained physicians and nurses, with the appliances and equipment for all details of treatment and all possible contingencies, is to-day recognized as the only rational method of treating the vast majority of diseases. Similarly equipped sanatoria are to-day recognized as indispensable to the curative treatment of tuberculosis.

STATE SANATORIA FOR CONSUMPTIVE POOR.

It is now everywhere conceded that it is the duty of the state to take a hand in this crusade against man's most insidious enemy by the education of the masses in hygiene, the enforcement of judicious sanitary laws and the provision of sanatoria for the treatment of the poorer people who form so large a percentage of her citizens, and for the protection and fostering care of whom she is responsible. Many countries abroad and several states in the United States and Canada have opened such sanatoria. That established at Rutland, Mass., has been in successful operation since 1898 and was the first institution of the kind supported by the state in America. New York has erected a state sanatorium at Raybrook in the Adirondacks and other states, among them Maine, Vermont, Rhode Island, Connecticut, New Jersey, Pennsylvania, Maryland, Louisiana, Minnesota and Ohio, have taken active measures for the erection and opening of similar institutions. The establishment of a state sanatorium for the treatment of tuberculosis in the state of New Hampshire, so ably discussed and warmly advocated by the commission of 1901, and subsequently endorsed by legislative action, let us hope, is soon to be accomplished.

The functions of such a sanatorium should be not only curative, but educational. It should aim to so instruct its patients that they may go from it as missionaries of hygiene, that they may instruct their families in the sanitary conduct of home life, and by their personal example help in bringing about much needed reform in the hygiene of the home. It should afford opportunity for health officers and physicians to study the sanitation of tuberculosis and should be equipped for the scientific study of the tuberculosis question in all its phases.

REQUIREMENTS FOR A STATE SANATORIUM.

Location.—The site selected for a sanatorium should be at an elevation of from 1,000 feet to 1,500 feet above sea level, and should contain from 200 to 500 acres, according to the number of patients it may be planned to accommodate, and should be on dry, porous soil. That part on which the buildings are to be located should be protected on the north from the prevailing winds, and should be open and gradually sloping toward the south, permitting exposure to the largest possible amount of sunshine. There should be sufficient tillable land to provide for the needs of the institution, and ample pasturage for cattle. The location should be near enough to a railroad to be readily reached by patients and to facilitate the handling of supplies. The building should be sufficiently remote from a public highway as to avoid contamination of the air by dust. Proper attention must be given to the presence of an abundant water supply from a source above suspicion and to efficient drainage.

Buildings.—These should consist of a central block, containing administrative building, store-house, kitchen, laundry and power-house. Grouped about this administrative block should be pavilions for the patients, including an infirmary for each sex, congregate dining-room and wards, accommodating from twelve to twenty patients each. The buildings should be connected by covered corridors, should be heated from a central plant, and lighted by electricity. The bathing and sanitary accommodations should be of the most approved pattern. The wards should be so built as to receive the greatest possible amount of direct sunlight, and there should be an allowance of 2,000 cubic feet of air space for each patient. Such ventilation should be provided as will change this air several times an hour. There should be ample accommodation of wide verandas with a southern exposure. The sexes should be separated by the administrative block. Inexpensive shacks opened on three sides, of sufficient size to hold ten beds, and furnished with a dressing-room containing lockers and bathing facilities should be provided for sleeping in the open air. There should be a nurses' home at a distance of several hundred feet from the other buildings. A disinfecting plant and crematory for sputum, etc., should be provided. Laboratories for chemical and research work should be provided in connection with the administrative group or in a separate structure.

The outlook from the infirmaries and wards should be unobstructed by buildings, and the site should be so chosen that the views may be pleasing and restful to the patient.

In addition to the usual farm buildings, especial attention should be given to the erection of sanitary cow barns, and every facility provided for the cleanly collection of the milk and for its proper cooling. Patients should not have access to the cow barns or pastures.

Grounds.—The grounds about the building should be laid out with carefully graded walks, that the earliest exercise may be graduated and readily adapted to the patient's strength. Frequent seats and resting places should be provided where the patient may rest sheltered from the wind or direct rays of the sun. There should be an abundance of shrubs and flowering plants, which will not only be a source of pleasure to the patients, but the care of which may be made a means of employment and interest to those who are sufficiently convalescent to be benefited by some light work. On the well-sodded lawns such out-of-door amusements may be allowed as do not call for too active exercise, and here such games as lawn-bowls, croquet, archery, tether-ball, quoits, etc., may be enjoyed when prescribed by the physician.

ADMISSION OF PATIENTS.

The sanatorium being designed for the treatment of incipient cases only, it is of vital importance to the success of the undertaking that none but suitable cases be received. There should be two or three examining physicians appointed in each county to whom applicants for admission should be sent for physical examination. The reports on such cases as are found suitable for admission should be sent to the superintendent of the sanatorium and placed on file. As rapidly as vacancies occur these patients should be admitted in the order in which the reports from the examining physicians have been received. No patient should be retained in the sanatorium who is found, on further observation, to be unsuitable for treatment. Those cases should be excluded which have intestinal, renal or joint complications; a temperature running above 103 F., active laryngeal tuberculosis; extensive consolidation in both lungs; cavities, with constitutional disturbances, excessive in proportion to the area of lung involved. The favorable cases are those with slight constitutional disturbance and fair nutrition; pleuritic cases; cases beginning with hemoptysis without constitutional impairment; incipient cases. These are the classes of patients received by Dr. Trudeau at the Adirondack Cottage Sanatorium.

CLASSIFICATION OF PATIENTS.

For best carrying out the treatment and for the regulation of routine the patients should be classified according to their physical condition as follows:

1. Infirmary cases, including those with active lesions, the new patient under preliminary observation, and those suffering from intercurrent affections and exacerbations of temperature, hemorrhage or other incident of the disease.
2. Patients not on exercise, but who may be allowed some association with other patients.
3. Patients on limited exercise.
4. Patients who are sufficiently convalescent to be allowed full exercise and who are capable of performing some light occupation.

So far as possible this classification should be observed in the housing of the patients. Too free intercourse between the patients whose activity is restricted and those in the free exercise class creates an unreasoning and unreasonable discontent among the former, disarranges the discipline of the sanatorium and is a bar to progress in treatment.

The lines on which classification are drawn and the rules governing each class should be made so far as possible with a view to the patient's comfort and happiness, and a spirit of kindliness should prevail in all our dealings with them, but the classification must be rigidly adhered to and the rules strictly enforced. The whole environment should be made cheerful and the patient brought to have an interest both in his own welfare and in the best interests of his neighbors, but with the mutual understanding that the ultimate good to all concerned can be attained only by a careful observance of the discipline by every individual.

GENERAL PLAN OF TREATMENT.

In the practical application of the treatment each case must be considered separately, and the methods followed be adapted in a large measure to the needs of the individual, as determined by a rigid physical examination and a careful observation for several days under the care of a trained nurse (one trained for this particular work). Every patient on admission should, then, be thoroughly observed and the details of his treatment carefully formulated that he may follow a carefully prescribed course from the beginning.

The following general plan of treatment is subject to such individual modifications as may be from time to time judged to be desirable.

1. *Rest.*—The recumbent or semi-recumbent position and bodily and mental repose must be insisted on so long as the rectal temperature remains above 100 degrees F. All things which have a tendency to raise the pulse rate above 100 must be forbidden. At times mental rest must be absolute. At others a little light

reading, a game of chess, of cards or other quiet pastime may be enjoyed. The effect of all these things must be watched, and everything denied which is followed by any undesirable result. We must guard against too long continued or exciting conversation, tiresome visiting with friends, etc. It is the careful, judicious regulation of these little things that make for success in our management of the case.

The patient may be in bed or in a reclining chair. His position should be changed at intervals of an hour. If his condition is such that he can be dressed and use a reclining or steamer chair, he should get up and walk eight or ten paces every hour.

2. *Open Air.*—The patient must be in the open air as many hours as possible. He should average eight hours out of doors every day; in summer ten hours may easily be thus spent, in winter often not more than six; but at all seasons his attempt must be to attain the maximum in this regard. When possible, he should sleep in the open air also, and if he sleeps indoors it must be with windows open wide and the bed screened from draughts. This he must do, no matter what the weather, always, of course, with proper protection from wind, rain and cold. The infirmary should be provided with such means of egress and covered verandas that bed patients may be taken out into the open air whenever there is not a positive contraindication to such a procedure, the bed being wheeled directly out on the veranda. (Fig. A.)

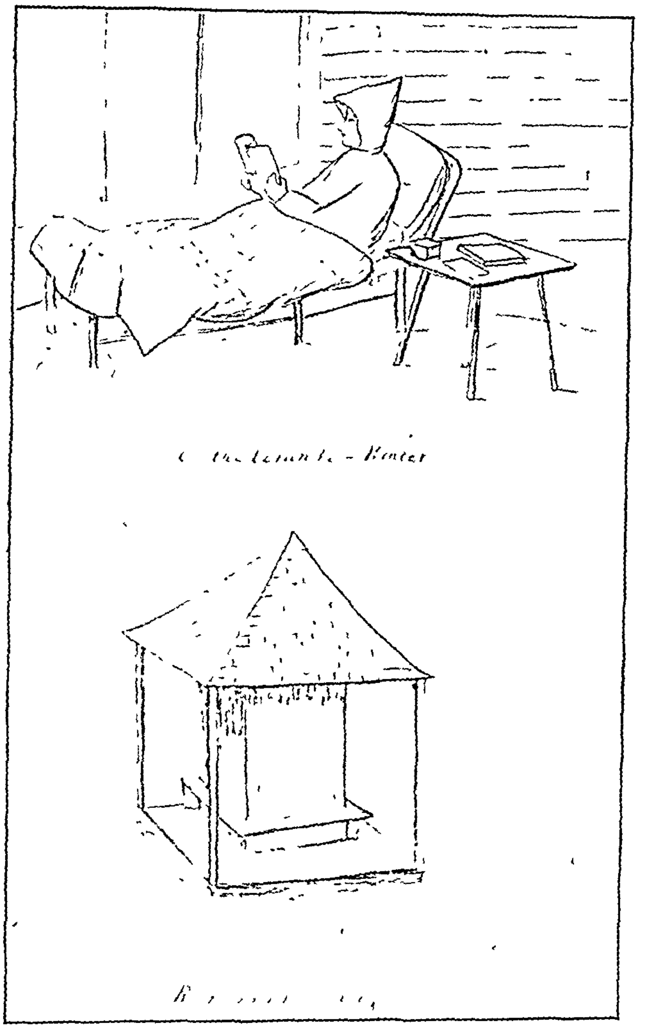

Figure A.

3. *Diet.*—The arrangement of the dietary and the preparation of the food should receive the careful personal attention of the physician. This is a matter of vital importance to the successful management of the tubercular patient. A person thoroughly trained in dietetics should be in immediate charge of the food preparation, giving attention not only to the quality of the food and its proper cooking, but also to the details of its service at proper temperature, and in a tempting, appetizing manner. As a rule, the appetite is poor without an actual digestive derangement, and the patient must be stimulated to eat by persistent persuasion, attractive service and sometimes catering to his fancy, before resorting to medication.

Fat and fat-forming foods must be administered freely, carbohydrates and proteids being given in due proportion. Milk, cream, butter, eggs and potatoes served in varied and pleasing ways offer the best means of attaining this end. Fresh meats, fish, vegetables, cereals and fruits should be freely supplied. The diet should be mixed and varied from day to day. The following dietary is given by Lucas to indicate the amount of the various forms of food necessary:

Breakfast.—Half a pint of porridge, with two ounces of sugar; two rashers of bacon, and two eggs (or chop, steak or fish), bread, four ounces; butter, two ounces; half pint of tea or coffee; milk, one pint.

Mid-day Meal.—Soup; fish, three ounces (or poultry), with butter, two ounces; two or three slices of meat, four ounces; potatoes, four ounces; cabbage and other vegetables, four ounces; pudding, six ounces; cheese, two ounces; bread, four ounces; butter, two ounces; milk, one pint.

Evening Meal.—Two eggs (or cold meat or fish), bread, six ounces; butter, two ounces; jam; half a pint of tea; milk, one pint.

The diet must be largely modified, according to individual needs. During febrile attacks a liquid diet must be prescribed and should consist of milk, raw eggs, meat broths, cocoa, meat juice and other concentrated liquid foods. At times the predigestion of food will be called for and sometimes lavage. Patients much reduced in flesh should be given milk with eggs between meals, and the feeding should be forced until the normal weight is gained. This being attained the diet should be but little in excess of the ordinary, as too much stuffing is liable to lead to digestive disturbance, with consequent loss of weight and a temporary relapse.

4. *Exercise.*—From the beginning of the treatment routine, systematic exercise should be practiced in order to increase the lung expansion and the volume of air habitually respired. A patient in bed may be taught to take eight or ten slow, deep inspirations, hold the breath a moment and then forcibly expire. He should breathe through his nose and take the exercise several times a day at stated intervals. The following respiratory exercise, given by Knopf,* is excellent for increasing the chest expansion, and can be practiced by nearly all class of patients.

Stand straight, with heels together, chest out and head erect.

1. Take a deep, slow inspiration, beginning with the abdominal muscles, and then expanding the chest to its fullest capacity, at the same time raising the arms from the sides to a horizontal position (Fig. 1). Hold the breath a moment and then lower the arms, at the same time making a somewhat forcible expiration.

2. A similar exercise, except that the upward movement of the arms is continued until the hands meet above the head (Fig. 2.)

3. Stretch the arms out as in swimming, the dorsal surfaces of the hands touching each other. During inspiration move the arms outward until they meet behind the back, bringing them forward again during expiration. (Fig. 3.) T

---

*S. A. Knopf: Prophylaxis and Treatment of *Pulmonary Tuberculosis*, P. Blakiston's Sons & Co. 1899.

exercise may be made more effective by the patient rising on his toes during inspiration, and descending during expiration.

4. Place the hands on the hips with the thumbs toward the front. Bend slowly backward as far as possible during inspiration. Hold the breath and remain in this position a few seconds, then rise somewhat rapidly during the expiration. (Fig. 4.)

Follow each respiratory act by a forcible secondary expiratory effort, pressing the thorax with the supinated arms to expel as much as possible of the supplemental air.

Massage and Swedish movements should be considered as forms of exercise and be brought into service during the first part of the treatment.

When the rectal temperature does not go above 100 F. in the afternoon the patient may be allowed limited walking exercise. At first a walk of a few rods may be taken and the rectal temperature determined one-half hour thereafter. If it is not elevated the exercise may be allowed regularly, and gradually increased, but must always be under careful regulation by the physician, and due regard paid to the effect on the temperature and other symptoms. No active muscular exertion must be indulged in until convalescence is established, but limited participation may be allowed in the various forms of less active lawn games, provision for which has been previously mentioned. Exercise may also be obtained by occupation of the patients in light gardening, the care of lawns and flowers, some of the farm work, and also, in the case of women, in the work of the household.

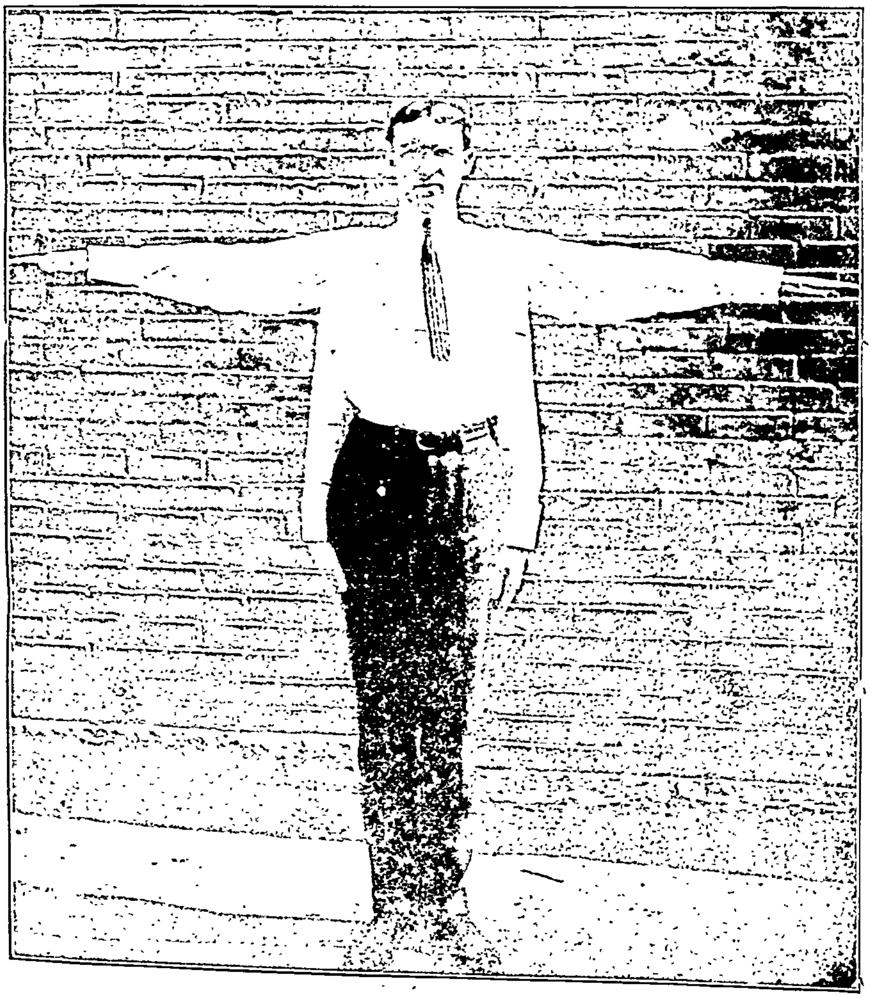

Figure 1.

5. *Bathing.*—On rising in the morning the patient should take a cold sponge bath or at least sponge the body to the waist with cold water. He should then rub himself briskly with a coarse towel until the skin is red and warm. If at first the cold water produces too much shock and there is no proper reaction, the use of a dry rub with a coarse towel should be substituted for the cold sponging. After a few days the dry rub should be preceded by sponging with lukewarm water, a few days later by alcohol and water, and then by water the temperature of which is reduced about 5 degrees each day until cold water at a temperature of 45 to 50 is used, or as it comes from the tap. The same method of bathing should be used for infirmary patients; the water and the friction being applied by the nurse. For cleansing purposes a moderately warm bath should be used twice a week and this should be followed by a cold affusion and friction of the skin of the whole body. Shower, spray and needle baths are excellent for stimulating nutrition and hardening the tissues or increasing the resistance to cold. The sanatorium should be equipped with hydrotherapeutic appliances for the administration of various forms of baths and douches in selected cases.

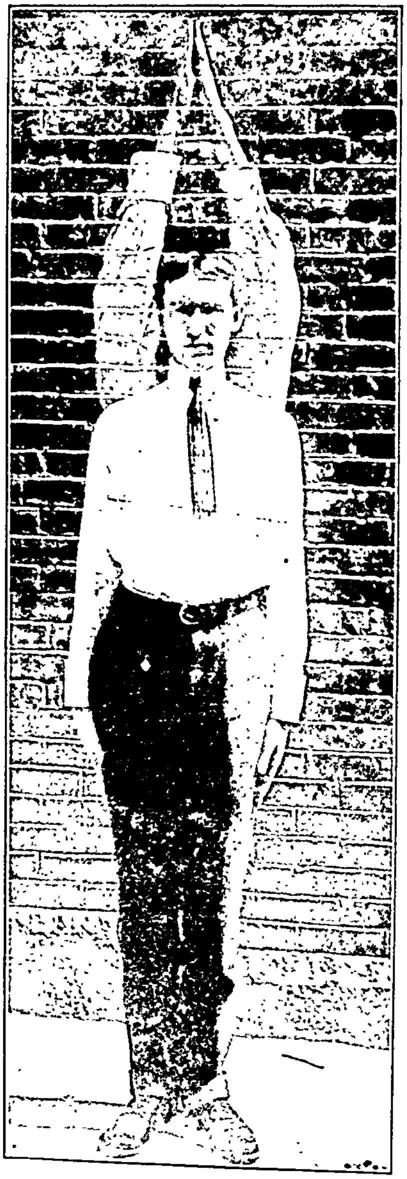

Figure 2.

6. *Sleep.*—The patient should retire at 9 o'clock and remain in bed until 6:30 a. m., between which hours absolute quiet should prevail in the sleeping quarter, thus allowing nine and one-half hours for sleep. Those who have suffered from insomnia generally rest well when taking the open-air treatment, particularly when sleeping out of doors. Being constantly in the open air during the day is conducive to sleep, and hypnotics will seldom be required. Gentle, cool sponging of the head and shoulders, or of the entire body, or cold compresses applied to the abdomen or extremities and covered with a flannel bandage are often efficient in inducing sleep. In more obstinate cases, wet packs, or massage, local or general, should be tried before resorting to hypnotic remedies.

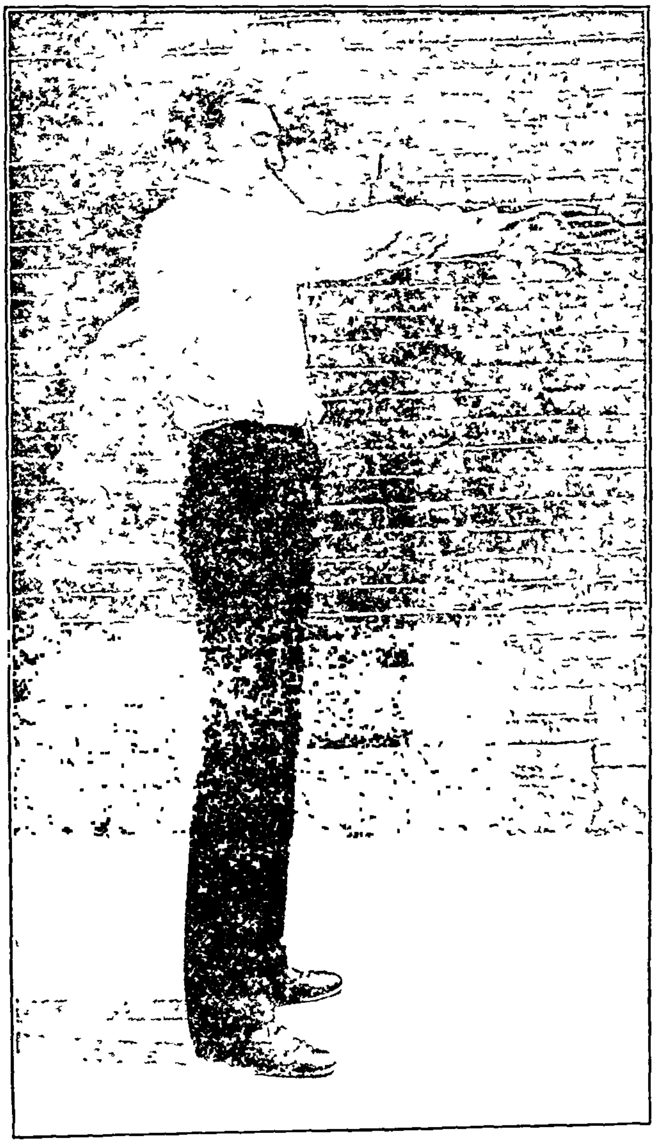

Figure 3.

7. *Symptomatic Treatment.*—In every case there is present, or constantly arising, some condition, anemia, malnutrition, digestive disorder, cough, hemorrhage, pleurisy, or other symptoms which require careful remedial treatment, but the discussion of which does not come within the scope of this paper. I would call attention, however, to the importance of maintaining the entire digestive tract in a healthy condition for the proper digestion of the increased amount of food taken and the thorough removal of waste. Constipation and consequent autointoxication must be guarded against. The teeth should be put and kept in good repair, and systematic attention given to the hygiene of the mouth.

DISPOSAL OF SPUTUM.

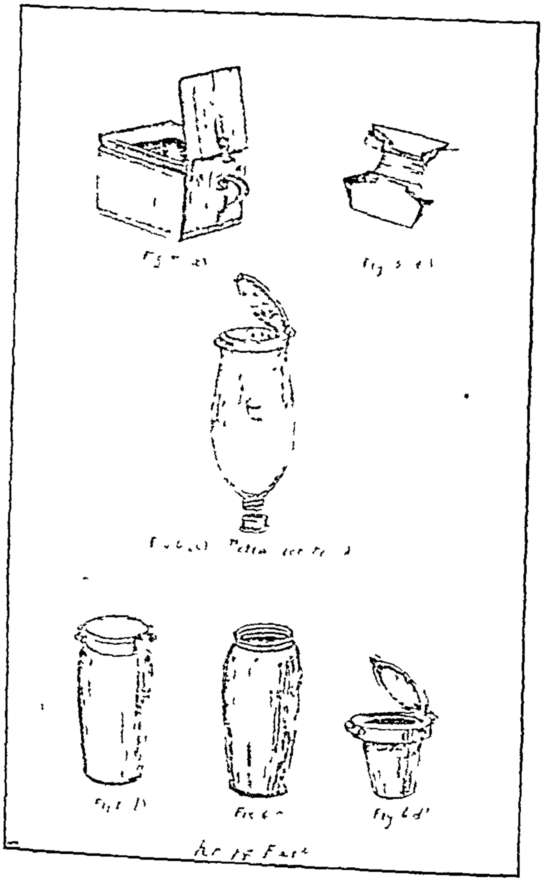
The thing of greatest importance in the sanitation of tuberculosis is the systematic and complete destruction of the tubercle bacilli. Since the bacilli are confined to the sputum in cases of incipient pulmonary tuberculosis, the thorough destruction of this excretion will effectually prevent the spread of the infection. Not only must great care be exercised in the collection of the sputum, but also the utmost cleanliness must be observed in the care of the utensils used and the cleansing of the hands, person and clothing, both of patients and nurses.

Every patient must be provided with a small sputum cup or flask, made of such material that it can be economically destroyed or thoroughly cleansed by antiseptics or by boiling. A useful form of cup is one ma of manila paper, which is supported in a metal fram with handle and cover. (Fig. 5). This cup is inexpensive and can be burned after use, and the frame well disinfected. When the patient is taking exercise and off on a walk a more convenient receptacle is a pocket flask like the Detweiler or the Knopf flask. (Fig. 6) These may be made of glass, but preferably of metal (aluminum) as the glass flasks are liable to be brok in the pocket, by dropping or otherwise, and are therefore less sanitary. A metal flask with tight joints and a properly fitting cover can be carried in the pocket, light, inconspicuous, cleanly and can be sterilized by boiling.

Figure 4.

The patient must be taught to always use his cup or flask for expectoration wherever he may be, and whether for the reception of sputum from the lungs or saliva from the mouth. He must never be without it. It must be at his bedside at night ready for immediate use; always by him during the day, at rest in his room, among his fellows on the veranda and in his pocket on his daily walks. The flask should be used only when away from the building, the cup at all other times.

Twice a day the paper cups should be emptied, their contents mixed with sawdust and burned in a furnace or sputum crematory. The paper cup should also be burned. The metal frames should be washed in a 10 per cent. solution of carbolic acid and refilled with fresh paper cups. The contents of the pocket flasks should be mixed likewise with sawdust and cremated, the flask being washed in a 10 per cent. carbolic acid solution, and boiled for one-half hour in a 1 per cent. solution of carbonate of soda. The nurse who has charge of this operation—and it should always be done by a completely trained person—must wear rubber gloves and a washable sleeved apron during the procedures.



Figures 5 and 6

The use of stationary cuspidors about the buildings and grounds is not to be commended. Although many individuals pride themselves on their ability always to expectorate in the cuspidor, many are they who fall wide of the mark and even miss the target altogether. In respect to the memory of these delinquents it is well to insist on the individual use of sputum cups on all occasions. An exception might be made on the use of a cuspidor in the toilet rooms. Here is a strong temptation, which is seldom resisted, to use the hopper for expectoration. This must be forbidden, and that the restriction may be well obeyed, it is well to have a cuspidor in a convenient location raised two and one-half or three feet from the floor. Cuspidors, if used at all, should be of iron, which can be sterilized by heat; should always contain a quantity of an antiseptic solution and should have well-fitted covers to prevent evaporation or the access of flies and other insects to the contents.

If the sputum cup is spilled or sputum is deposited in any way on the furniture, floor or about the grounds or on the clothing of patients, the nurse, being notified at once, should immediately remove the infectious material and properly disinfect the place before the sputum has time to dry.

If a patient is suffering from intestinal or bladder tuberculosis, or if there are any infectious discharges whatever, these should receive the same thorough antiseptic treatment as in a case of typhoid fever.

KITCHEN AND LAUNDRY STERILIZATION.

All knives, forks, spoons and dishes on which the patients are served must be disinfected after every meal. This can be accomplished by means of a sterilizer after the pattern of a dish washing machine, in which the dishes may be immersed, first in a strong, hot caustic lye and then in boiling water, on being removed from which they dry rapidly by evaporation.

At the table each patient should have his own napkin and rings or other device should be used so that these do not become mixed. The table linen and all bed and body linen should be sterilized by steam before going through the usual laundry operations. Clothing soiled with tubercular sputum, vomitus, etc., should be soaked in 10 per cent. solution of carbolic acid for an hour before being sent to the laundry. The patient's outer garments should be subjected to sterilization by formaldehyd gas at stated intervals, and on discharge from the sanatorium all his belongings and his wearing apparel should be similarly treated.

HOUSE DISINFECTION.

Experiment and careful observation have demonstrated that the wall and floors of properly conducted sanatoria are comparatively free from tubercle bacilli. Also that the walls seldom become infected above a distance of three feet from the floor. The floor should be gone over daily with a mop moistened with a 1 per cent. solution of chlorinated lime and the mop put into boiling water after use. Once a week the furniture and the walls, to a height of three or four feet, should be wiped with cloths moistened with 1 per cent. solution of chlorinated lime, and the cloths burned. The floors and walls to a height of six feet should receive a weekly scrubbing with soap and water. Once a month the rooms should be disinfected with formaldehyd gas. The various articles in the room should be left in place and books should be stood on end and opened so as to separate the leaves freely. Any one seeing a tubercular patient reading and coughing as he reads and noting in this act the spraying of the open page with fine droplets of mucus, will realize the danger which arises from the drying of these droplets containing, as many of them do, the tubercle bacilli. The frequent disinfecting of books used by patients, then, becomes a matter of importance. All rugs, mattresses and pillows should be exposed weekly to the bright sunlight for several hours.

In the construction of the building all corners should be made round for most efficient cleansing.

PERSONAL HYGIENE.

Mention has been made previously of the proper care of the skin and the hygiene of the mo The

1. Absence of symptoms and physical signs of active disease.
2. Absence of tubercle bacilli from the sputum in repeated examinations.
3. Return to normal strength and maintenance of body weight at or above normal.

The length of time necessary for the accomplishment of these results will depend on the progress made by the disease before admission and the zeal which the patient displays in carrying out the prescribed treatment. The more conscientious he is in living up to the spirit and the letter of the régime, the more immediate and certain will be the results. Except in the most incipient cases six months should be put down as the minimum time to be spent in the sanatorium. There are occasional patients whose symptoms become quiescent and who can be discharged after a residence of three months, continuing at home the routine which they have learned. Many cases will show signs of active disease after twelve months' residence. This, as a rule, should be the maximum duration of residence in a public sanatorium where there is constant great pressure for the admission of recent cases. After this length of time any person of ordinary intelligence should be able to carry out in practice at home the principles with which he has become familiar by association and teaching, and the way should be made for the reception of others who may be waiting and losing ground for want of proper guidance.

RESULTS OF SANATORIUM TREATMENT.

Some such classification as the following is usually observed on discharging patients from sanatorium treatment: Apparently cured. Lesion arrested. Improved. Not improved. Those patients are discharged as "arrested" in whom all active symptoms have disappeared, who have no cough, no bacilli, and whose temperature and weight are normal. The patients discharged as cured are those who have passed a considerable interval, usually from six to twelve months, in apparently good health.

The following figures are taken from the Seventh Annual Report of the Massachusetts Sanatorium for the year ending September 30, 1903:

of carbonate of soda. The nurse who has charge of this operation—and it should always be done by a completely trained person—must wear rubber gloves and a washable sleeved apron during the procedures.

The use of stationary cuspidors about the buildings and grounds is not to be commended. Although many individuals pride themselves on their ability always to expectorate in the cuspidor, many are they who fall wide of the mark and even miss the target altogether. In respect to the memory of these delinquents it is well to insist on the individual use of sputum cups on all occasions. An exception might be made on the use of a cuspidor in the toilet rooms. Here is a strong temptation, which is seldom resisted, to use the hopper for expectoration. This must be forbidden, and that the restriction may be well obeyed, it is well to have a cuspidor in a convenient location raised two and one-half leads to very favorable results, about 50 per cent. of such cases being very greatly benefited, and some cures resulting even in cases seeming most unpromising. Statistics drawn from resorts receiving all classes of cases, even the most far advanced, show an increase in weight and general health, and decrease in fever, cough and expectoration in 80 per cent. with a return in approximately normal health in over 30 per cent. Thus we see that while the sanatorium treatment is beneficial in all stages of tuberculosis it is the earliest incipient cases which derive the greatest benefit, and are returned with the least delay to their homes and occupation. Thus, the very great importance of an early diagnosis is emphasized, and there is no question but that with earlier recognition of the disease by the use of all diagnostic measures on the slightest suspicion, and the immediate resort to sanatorium treatment a very much larger proportion of cures will be effected, and much time, expense and many valuable lives saved.

FOLLOWING OF PATIENTS AFTER DISCHARGE.

It is important to keep track of patients after their discharge, and to ascertain from time to time their condition and the ultimate result. At intervals of three, six and twelve months after discharge the patient should be required to report to the sanatorium his present condition on a printed form mailed to him for the purpose; or to report in person to the nearest examining physician and a physical examination made, the findings of which should be sent to the sanatorium and put on file with the record of the patient. Thus there would be obtained a record covering a period of two years following his discharge. To supplement this, inquiry should be instituted as to the whereabouts and condition of discharged patients at intervals of two or three years. In this way there would be collected in time valuable statistics as to the ultimate results of sanatorium treatment showing the per cent. of permanent cures, the duration of arrests, the frequency of relapses, the length of life, the causes of death and other facts of importance in the guidance of future therapeutic work.

CONCLUSION.

In conclusion I would call attention to the importance of continuance by the patient of a hygienic life after he leaves the sanatorium. In his home and place of work there must be proper ventilation and cleanliness, the latter term including adequate disinfection. These things are necessary for his own safety, for the protection of his family and his business associates. His food
wall ıst be of the most nourishing, and his whole life well
scrul lered and lived after the manner his institution ex-
room rience has taught him. Not only should he practice
The se things himself, but he should be an apostle of the

PULSATING EXOPHTHALMOS; SUCCESSIVE LIGATION OF BOTH COMMON CAROTID ARTERIES; DEATH.*

HOWARD F. HANSELL, M.D.

PHILADELPHIA.

Patient.—S. C., a strong, healthy-looking girl, 22 years of age, applied at the eye dispensary of the Jefferson Medical College Hospital July 30, 1903. She complained of pain in the left eye and left side of the head, and of a constant subjective noise.

History.—On the evening of July 3 she was struck on the inner angle of the right orbit, between the internal canthus and the nasal bone, by the handle of a heavy butcher knife, thrown from a distance of about 15 feet. Both lids of the right eye were bruised and slightly cut, and the nose bled, but other than these insignificant injuries she suffered no immediate ill effects. On the following day she noticed a noise in the head, which she referred more particularly to the *left* side. Two weeks later the left eye became prominent.

Examination.—At the time of the first examination proptosis was marked, pulsation of the eyeball was present, and a bruit was distinctly heard by applying a stethoscope to any part of the head, or over the large vessels on both sides of the neck, and louder over the closed lid of the left eye. It was diminished by pressure on the vessels of the neck. A distinct thrill was communicated to the finger, laid on the termination of the nasal artery on the nasal bone. A superficial vein in the outer half of the left upper lid was greatly dilated and tortuous and the lid was discolored and swollen. The eye was dislocated outward and downward. Movements in all directions were limited, particularly inward and upward, and diplopia was noticed in all parts of the binocular field. The sclera was deeply injected, the media clear, the pupil dilated and slowly reacting and the interior of the eye healthy. Tension normal. The pain in the orbit was constant and severe and increased by the recumbent position. The eyeball could easily be replaced in the orbit, but the exophthalmos returned immediately after the compression was relaxed.

September 3. L., pupil measure, 5 mm.; R., 3 mm. The left reacts sluggishly to light and accommodation, V. = 6/6, with correction of + 3 D. There is no change in the appearance of the fundus; the optic papilla and the retinal and choroidal vessels remain perfectly normal. There was a slight systolic murmur over the apex of the heart.

Course of the Disease.—After observation in the out-patient department for several days, the symptoms increasing in severity, Miss C. was admitted to the hospital. She was put to bed, kept absolutely quiet, and free from all physical exertion, and given large doses of potassium iodid.

During this time Dr. W. W. Keen and Dr. S. S. Cohen confirmed my diagnosis of arteriovenous aneurism in the cavernous sinus. The eye became more prominent and less mobile, the veins of the lid more and more injected, the largest measuring 2-3 mm. in diameter, the noise and pain more unendurable in spite of treatment. Pulsation and bruit could be readily observed at the nasal side of the internal canthus, and with the stethoscope applied to the closed lids, a continuous pulsation with distinct increase in the sound with each contraction of the heart was heard. This bruit could be detected not only over the left eyeball and temple, but on the entire left neck, cheek and over the right eye and cheek, and at a point under the right jaw.

Urine.—Amber, 1,012, neutral, a trace of albumin. No sugar, urea 1.3 per cent., triple and amorphous phosphates, squamous and columnar epithelium, a few leucocytes and erythrocytes. No casts.

After a few days of rest and medical treatment she left the hospital, unimproved. She re-entered Sept. 24, 1903.

SURGICAL REPORT BY DR. KEEN.

I saw her again on September 25. I confirmed the observations made by Dr. Hansell, and agreed with him in the suggestion that the left carotid should be tied. Before this could be done, the exophthalmos had evidently increased and the vein in the upper lid was distinctly more pronounced and more tortuous. The thrill and bruit also were more marked than before.

Operation.—September 30. I ligated the carotid with silk on a level with the cricoid cartilage. I did not see the descendens noni nerve, the jugular vein, nor the pneumogastric nerve. Dr. Hansell examined the eye-ground by the ophthalmoscope as I tied the carotid. The instant that the ligature was tightened all the arteries faded so that they were invisible. Both he and I afterward examined for bruit and thrill and found both gone. At the time of the ligation of the artery also the blood pressure was observed, by the Riva Rocci apparatus. It rose 15 mm. and the rise was maintained after the operation.

Result.—Her temperature never rose above the normal and she made a perfect operative recovery in a few days. (The aneurismal bruit returned, so that it was perceived through the stethoscope as a faint continuous murmur at 4 p. m. on the day after the operation, 25 hours after the operation was concluded. The exophthalmos diminished greatly immediately after the operation, though the eyeball was still somewhat more prominent than the other, so that it was only moderately noticeable. She said she subjectively perceived the sound, but that it was very slight and far less annoying than it had been before the operation. She left the hospital Oct. 10, 1903.

She re-entered the hospital on November 8, on account of the recurrence of all her symptoms, especially the annoyance caused by the bruit. The exophthalmos, also was distinctly greater than when she left the hospital. Dr. Hansell observed for the first time, also, distinct retinal hemorrhages so that she was going from bad to worse, and the integrity of the eye was threatened. This forced us to a second operation immediately, though I had hoped not to tie the other carotid at all, or at least, to defer the ligature for several months, so as to allow of the establishment of the collateral circulation.

Second Operation.—November 11. In view of the retinal hemorrhages, increase of bruit and of the exophthalmos I ligated the right carotid, under local anesthesia, by a solution of adrenalin and eucain. The only time when she had the least pain was when I was separating the sternocleido from the tissues about it by blunt dissection, so as to expose the artery. The solution had not infiltrated so deeply as this. She expressed herself as much better satisfied with this method of anesthesia than with the ether. When I had sutured the wound, I was very much struck with the absolutely blanched appearance of the skin as a result of the adrenalin. It was a dead white over an area which extended above, below, and to a considerable distance both to right and left of the incision. At the moment of tightening the ligature, Dr. Hansell observed the eye ground of the right eye. The moment the ligature was tied, the arteries disappeared as before.

Result.—So far as the wound was concerned, it healed by primary union without any rise of temperature whatsoever. On the second day after the operation she showed a little drowsiness. This deepened and on the third day was very marked. That day, November 14, she had a series of convulsions during the afternoon and evening. On the 15th (the fourth day), she was paralyzed on the left side, and a number of convulsions occurred, becoming finally almost continuous. She died at 10:26 a. m., November 16. Dr. Hansell and I urgently requested a postmortem, and saw the family personally, but they absolutely refused it.

While there may be other causes for pulsating exophthalmos, rupture of the carotid artery in its passage through the cavernous sinus is stated by de Schweinitz to be the pathologic condition in about 60 per cent. of the 200 cases reported up to 1899. In the present ca it is impossible in the absence of a postmortem to be absolutely certain that this was the condition, but it is probable for the following reasons: First, the pulsating exophthalmos; second, the continuous throbbing bruit which was markedly increased during systole and diminished, but did not disappear during diastole of the heart; this would seem to be the most important reason; third, the thrill which accompanies an arteriovenous aneurism; fourth, the passive enlargement of the veins.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

I regretted extremely the necessity of ligating the opposite carotid so early as six weeks after the first ligature, for I greatly feared that the collateral intracranial circulation might not be well established, and that so early a ligation might prove fatal. The increasing retinal hemorrhages which threatened the integrity of the eye, however, compelled us to do the second operation.

Murray[1] reviews the subject of pulsating exophthalmos at some length. Seventy-one per cent. of the 197 cases reported up to 1898 followed traumatism, and 29 per cent. are due to existing chronic endarteritis of the internal carotid artery. In speaking of the therapeutics, he says that of 53 cases treated by digital compression, 15 were cured or improved; by ligature of the common carotid 51 per cent. were cured, 17 per cent. improved, 17 per cent. unimproved, 10 per cent. died. The mortality following the operation is only 10 per cent., while the death rate following the same operations for the cure of other conditions than pulsating exophthalmos is 25 per cent. (Wyeth gives 43 per cent. in 789 cases). He quotes Boden in reference to the frequency and mortality of double operation, who reported in 1899 that there had only been 6 cases of ligature of both common carotids, the interval between the two operations in 4 of the 6 cases being thirty days, fifty-four days, sixty days, thirty-two days. Five of the six patients were cured or improved, and none died.

The most recent compilation of the papers that have been published on the subject is that by Barnard and Rugby.[2] These writers report a case in which a bullet passed through the roof of the mouth to the base of the skull, which was perforated and smashed. The left side of the face was paralyzed and the left pupil was dilated and fixed. The lids were swollen and very prominent, all the external ocular muscles paralyzed, the cornea insensitive and the eye pulsated vigorously. A thrill was felt and a bruit heard over the closed lids. Ligature of the left common carotid artery was performed. The proptosis diminished and the pulsation disappeared for four days, recurred and disappeared again in ten days, but the eye was blind from opacity of the cornea. Two months later the patient complained of headache. The bullet, which was located by the x-rays above the petrous bone in the temperosphenoidal lobe, was probably surrounded by purulent degeneration of the cerebral matter. The postmortem showed the presence of a double sacculated aneurismal dilatation in the intracranial course of the internal carotid artery. There was no arteriovenous communication in the cavernous sinus. The interest in this case lies in the presence of all the typical signs of traumatic pulsating exophthalmos due to the unusual lesion of a sacculated aneurism of the carotid artery. The authors collate statistics both in favor of and against ligation of the common carotid. Rivington[3] in 44 cases, both idiopathic and traumatic claimed about 50 per cent. of cures. LeFort[4] claimed 61 per cent. successful, of which 54 per cent. were cured. The results of compression are much less favorable, according to LeFort, who gives 86 per cent. of failures.

This author says: "If the exophthalmos is double and ligation on one side has failed, and if pressure on the other side checks pulsation and bruit, one should not hesitate to tie the other carotid." C. S. Bull[5] says: "Ligation of the carotid is the oldest operation for the relief of pulsating exophthalmos, and has given the most satisfactory results. As a rule, the pulsation and bruit disappear immediately, any existing tumor collapses, the eye often sinks back into the orbit, and the tension and distension of the veins in the orbit diminish. Faint subjective sounds may return after a few hours, but the other symptoms soon entirely disappear. The swelling of the lids and the chemosis vanish, the exophthalmos lessens, the motility of the eyeball returns, and the vision is gradually restored. The swelling and cloudiness of the optic disc subside, the retinal veins become less engorged and tortuous and the hemorrhages are absorbed. Paresis of one or more of the ocular muscles sometimes remains for a long period unchanged. In most of the cases, the cure is complete in six weeks."

REMARKS.

The return of the affection after ligation may be due to deficient coagulation of blood, or the veins may close on the same side, but the blood finds its way to the other side through the circular sinus, or there may be a fresh aneurism, or the superior ophthalmic vein of the side first affected has been obliterated at its opening into the cavernous sinus by the thrombosis of the sinus produced by the ligation of the carotid. The cavernous sinus subsequently regains its permeability, and the still yielding cicatrix in the arterial wall yields and opens again. The arterial blood again enters the sinus, passes through the circular sinus into the cavernous sinus of the opposite side, and produces here the symptoms of pulsating exophthalmos.

As against ligation, it is urged that there are records of several cases in which the physical signs and symptoms had existed a long period with little marked effect on the well-being of the patient or little danger of death. Among them is a traumatic case by Williamson[6] that had persisted twenty-three years; one by Frost,[7] twenty-one years; one by Brown,[8] sixty-five years.

As a second argument is the recurrence of the signs and symptoms after ligation, and as a third is the possibility of a spontaneous cure.[9] Rivington's statements of postmortem findings in 12 cases are interesting. In no case was there simple traumatic aneurism; in 3 direct communication between the artery and vein in the cavernous sinus; in 1, aneurism of each ophthalmic artery; in 1 simple dilatation of the carotid artery; in 8, the ophthalmic veins enlarged and varicose. Up to 1898, 197 cases were published without settling the question of cause, course or treatment.

INTERMITTENT EXOPHTHALMUS, WITH REPORT OF A CASE.*

WM. CAMPBELL POSEY, M.D.,

PHILADELPHIA.

Patient.—C. McL., a drug clerk, 21 years of age, consulted me eighteen months ago at the Wills Eye Hospital, on account of a feeling of "looseness" in the left eye, and for the correction of a tendency which the eye had to drop forward when he inclined his head forward or made slight muscular exertion.

History.—The patient said that his mother had noticed when he was but 4 years old that when he stooped to tie his shoe laces the left eye became swollen, but recovered its natural appearance as soon as he regained the upright posture. This tendency to protrusion of the eyeball persisted until he was 12 years of age, when he had a severe fall, striking his head, after which it was thought that the eye fell forward oftener and to a greater degree than before the accident. Of late years he had remarked that the eye could be made to protrude by simply holding his breath. There had been no pain nor inflammatory symptoms in either eye at any time and vision was unaffected except for a slight blurring in the left eye at the time of the protrusion. It was elicited that the patient had had diphtheria when he was 3 years of age, but it could not be ascertained whether the peculiar behavior of his left eye antedated this affection or not. Other than this attack of diphtheria, his health had been good. His family history was also good and there was no record of an ocular affection similar to his own in any of his relatives or ancestors.

Examination.—With the patient sitting quietly in a chair (Fig. 1), with his muscles relaxed, both eyes presented a normal appearance, save for a slight dilatation of the palpebral fissure of the left eye; the moment, however, that the head was bowed forward, or the breath held for a time, or pressure made on the jugular vein, the left eye began slowly to protrude from the orbit, being driven straightforward in the axis of the orbit. As the globe was proptosed, the upper lid drooped slightly, covering about 2 mm. of the upper portion of the cornea, while the lower lid fell away from the globe, showing about 6 mm. of clear sclera. If the muscular strain was continued the proptosis became even more marked, the lids becoming blue and swollen, the inferior tarso-orbital sulcus bulged out and was obliterated, and the superficial veins about the orbit became much distended (Fig. 2). Finally, the degree of the exophthalmus became so marked that there appeared danger of the globe becoming dislocated in front of the lids. The moment the strain was removed, however, the eye sank rapidly back into its place and in a few moments had resumed its natural position in the orbit.

The position of the right eye was unaffected throughout. No bruit could be felt or heard over the left eye at the time of the proptosis, and it was noted that even light pressure on the globe was followed by a remarkably easy recedure of the globe, the eye seeming to drop back further into the orbit than is the case under normal conditions. In the quiescent state the excursions of both eyes were normal, the pupils were of slightly different size, that of the right eye being 2½ mm., that of the left 3 mm.; both reacted normally to light and convergent stimuli. The ophthalmoscope revealed slight hypermetropia in both eyes and normal and similar fundi with nothing unusual in the course or distribution of the retinal vessels. At the time of the proptosis, however, it was noted that the vessels in the left eye became rounder and fuller and more cordlike, this being particularly true of the veins. The vision in each eye equaled 5/5, but at the time of the proptosis the vision in the left eye fell to 5/7½. The patient was sent to the Polyclinic Hospital for further study, and, at my request, an examination was made of the general condition by Dr. Riesman, and of the throat and nose by Dr. Freeman. Dr. Riesman's report is as follows:

"The patient is somewhat undersized and of spare build. The forehead is low; there are dark rings under the eyes; the tongue is clean and moist. The neck is large and broad, especially at the level of the thyroid cartilage, becoming narrower above. In the quiescent state, this enlargement of the neck appears to be principally due to a bulging of the sternocleidomastoid muscles in their middle third. The thyroid is palpable but not enlarged. The chest is well formed; there is a delicate fringe of distended capillaries across its lower portion, in the hypochondriac region.

"The heart boundaries are: On the right, a little to the left of the right sternal border; above, the top of the fourth rib; on the left, a line one inch within the nipple-line; below, the fifth interspace. The apex-beat is indistinctly palpable in the fifth interspace, an inch and a half within the nipple-line. Auscultation shows slight accentuation of the second aortic sound. The pulse is 92, and distinctly dicrotic. The radial artery is a little thickened.

"The liver dullness extends from the fifth interspace in the right mammary line to the costal margin. The spleen is not enlarged.

"When the patient is asked to proptose the eye, he takes a deep inspiration and holds his breath. For a short time no movement is observed in the eye; then it is forced forward, the patient's face becoming, at the same time, red and congested. The pulse slows down during the bulging, and is eventually arrested. At that time the heart sounds can not be heard; on auscultation nothing is detected except a continuous, faint hum, produced by the chest muscles, which are in a state of high tension. The cardiac arrest lasts about fifteen seconds. Rather suddenly, the heart sounds again become audible, but they are feeble and show a marked increase in rate (144). The sounds gradually become stronger and slower, until they fall to the normal number. During the proptosis, the neck becomes greatly enlarged, and the patient looks as though he had a huge goiter of the lateral thyroid lobes. The neck measurements are as follows:

	During rest. cm.	During proptosis cm.
At the top	36	37
At the middle	36	38
At the base	38	30.5

"*During the respiratory arrest, the lung expands in all directions and the percussion note becomes more tympanitic. The boundary of the lung descends posteriorly* about 2 cm.; *anteriorly, in the right nipple-line, 3.5 cm.,* so that the upper border of the liver dullness is at the seventh rib. The heart dullness becomes diminished, the left border being 1 cm. within the line previously given. During the asphyxia *there is also a marked distension of the veins* on the backs of the hands, with increase in congestion. These veins are however, even during rest, abnormally conspicuous."

The examination of the throat and nose by Dr. Freeman was reported as follows:

"The neck is very large at the base, so that a fifteen-inch neck band is tight. Above the collar, the neck appears normal; it is even quite small. The neck band raises decidedly with each pulsation of the heart and there is considerable throbbing of the blood vessels of the neck, chiefly marked on the left side. Pressure on the jugular near the larynx causes the left eye to protrude. The eyes are rather sunken, especially the left. The left fossa is rather obstructed by full turbinals, and the mucous membrane on that side is abnormally hyperemic. This is most unusual, as active congestion of the superficial blood vessels is seldom seen limited to one side. The mouth, throat and rhinopharynx are practically normal. The transillumination test shows both antra perfectly clear and a faint glow is seen through the pupils. When, however, the effort is made to protrude the eyeball, as by pressure on the neck, or holding the breath, the light entirely disappears from the upper part of the face, this being more slowly *apparent on* the right side. The condition whether of a *varicose* nature or not, seems to affect both bits and the upper part of the nose, though it is much more pronounced in the left eye. I believe the enlarged condition of his neck exerts a marked influence on the return circulation from the head, bringing the veins directly under his muscular control."

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

The case which has just been described is an instance of that rare condition known as intermittent exophthalmus, the chief characteristic of which is an abnormal mobility of the eye in an antero-posterior direction, in consequence of changing volume in the contents of certain of the orbital veins. The name *"Exophthalmus a volonté"* has also been given to the condition, as subjects of this affection are able to change the position of the globe at will. Others designate it as "alternating enophthalmus and exophthalmus," as descriptive of the condition which exists in some cases. Of these three names, the one chosen as the title of this paper is to be preferred, for voluntary exophthalmus is a misnomer in those cases where the globe proptoses involuntarily, while the title can not be applied to all cases, since enophthalmus is not always found.

That the affection is a rare one is attested by the fact that I was able to collect but 39 other cases in all ophthalmic literature. It is probable, however, by reason of the greater number of cases reported in recent years, that the disease is not so rare after all, and that the infrequency with which one encounters reports of cases of intermittent exophthalmus in the literature is attributable to ignorance of its peculiar characteristics and to its being classed among the ordinary angioma of the orbit. Popular text-books in the English language make no mention of it, indeed, a rather careful search through German and French textbooks as well discovered references to the affection in but two of these. All the monographs have been written by German or French observers. Although cases which were undoubtedly instances of intermittent exophthalmus had appeared in the literature much earlier, Dupont was the first to give a satisfactory description of the affection, in a monograph which appeared in 1865. This author referred to four cases which had already appeared in the literature, and gave a full description of the symptomatology, course, diagnosis and etiology of the affection. The next article of importance was that of Sattlers[1] in 1880, and a year later Yvest[2] referred to the four cases already reported by Dupont[3] and added three others. In 1893, Sergent[4] collected most of the cases which had been already reported, wrote of their symptomatology in a comprehensive manner, and divided the cases into three groups. The next contribution of importance was in 1894, and appeared in Panas'[5] text-book. A year later, 1895, Van Duyse[6] reported a case and dwelt at length on the symptomatology of the affection. In the same year, April, 1895, Becker[7] published the most complete article which had appeared up to that time, citing nineteen cases from the literature, and reported two additional cases of his own. Two years later, 1897, Vossius gave another masterful exposition, but, being ignorant of Becker's article, repeated much of the contents of that author's paper. Vossius rejected the earlier cases referred to by Dupont and Sattler and included by Becker in his list, either on the ground of insufficient data or as manifestly of a different nature from typical cases of intermittent exophthalmus. In 1898 Scheffels[8] reported another case and rearranged the cases into groups differing somewhat from the previous authors.

In addition to these more or less elaborate monographs, reports of individual cases have appeared from time to time, without particular comment by their authors on the pathogenesis or symptomatology of the affection. But two cases, in addition to the one which I report, have been described by American authors, one by R. Sattler[9] and one by Grüning,[10] and only three by Englishmen, i. e., Collins,[11] Lang[12] and Bickerton, the remaining thirty-five having been seen in Europe.

The last article on the subject was by Hitschmann,[13] in July, 1900, and in conjunction with one by the same author which appeared six months earlier, is the most exhaustive treatise on intermittent exophthalmus which has yet appeared.

SYMPTOMOLOGY.

As already noted in the case which has been reported by me, and which may be regarded as a typical instance of intermittent exophthalmus, the characteristic symptoms of this affection consist in a more or less rapid, steadily forward movement of one eye when the body assumes a position which places the head in a dependent position, or when the flow of blood from the head to the trunk is impeded to any extent, either by voluntary act of the subject, as holding of the breath, or by pressure on the jugulars, coughing, sneezing, binding the neck with tight collars, etc.

The proptosis is either directly forwards or the globe may deviate to some extent from the anteroposterior axis of the orbit. The exophthalmus attains its maximum as a rule in about five seconds, and the eyeball rapidly recedes as soon as the conditions favoring it have been removed. Actual measurements show that the globe is driven forwards from 10 to 15 mm.; in one case the degree of the proptosis was so great that the globe was actually dislocated in front of the lids (Lacompte).[14] As in the case I reported, ptosis may appear when the exophthalmus is beginning to be marked, and may attain a degree sufficient to cover the upper part of the cornea.

[14] Lacompte: Exophthal. a volonté. La Belgique Méd., 1897, 28 Oktober; Revue Générale d'Ophth., 1898, No. 2; Nagel's Jahresberichte, 1897.

As was well shown in the case which has just been described, even when the exophthalmus had attained its greatest degree, there was little or no alteration visible either in the exterior or in the interior of the eyeball itself; the lids, however, became distended and a bluish tinge was imparted to them and to the skin surrounding the orbit. If there are any varicosities of the veins of the skin and conjunctiva, they become filled at the same time with the proptosis of the globe. Sometimes a venous tumor can be seen and felt, either behind or alongside of the globe; in most of the cases, however, no such tumor can be demonstrated. Bruit and pulsation over the eye are absent. The proptosis is usually unaccompanied by pain and in many cases the subjects themselves are unaware of the protrusion of the eye until their attention has been called to the fact by another. Usually, however, there is an unpleasant sensation of pressure and fullness in the orbit when the head is bowed forward, as though the eye were starting out of its socket. In some of the cases, especially those in which the exophthalmus is of extreme degree or persists unusually long, there is quite severe pain and tenderness in the orbital region, which may be accompanied by vertigo.

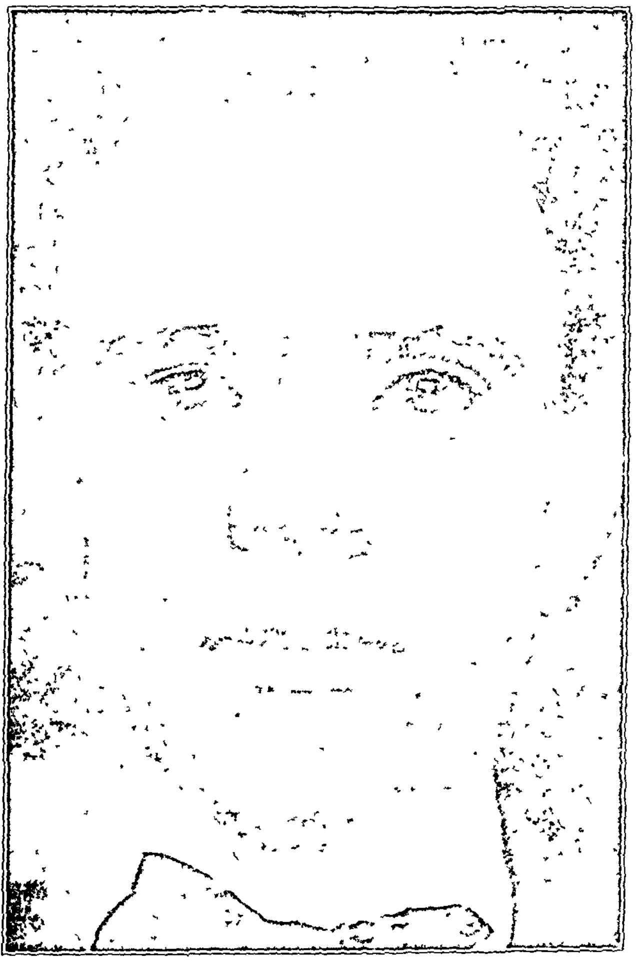

Figure 1.

When the head is held in the upright position and the conditions which favor exophthalmus are absent, the eye presents either a normal appearance or one of slight enophthalmus, so that it resembles an artificial eye. In some cases there is slight proptosis and the tarso-orbital fold is deeper. The size of the pupil is usually unaltered, though in several of the cases it was noted as being dilated and in others contracted. Vision may not be affected, even at the height of the exophthalmus; generally, however, it is lowered when the proptosis is extreme, but becomes normal with the return of the eyeball to its normal position in the orbit. In a few cases vision may be much affected permanently, or even absolutely lost; in all such there are complications of various kinds, such as retinal hemorrhages which occasion disease of the optic nerve. Vision may be disturbed by derangement of the balance of the extraocular muscles, and diplopia has been recorded in several instances.

In many of the cases no change could be noted in the fundus, either during the exophthalmus or in the interim; in others, on the other hand, there was a dilatation and tortuosity of the retinal veins, the retinal vessels became empty and much reduced in size and the head of the nerve veiled, the normal appearance quickly returning to the fundus, however, as soon as the globe regained its normal position. Phlebectasia of the retinal vessels and of the conjunctiva was observed in a case by Hitschmann, and retinal hemorrhages have been noted by several observers. The tension is normal Pressure on the eye, however, causes it to sink back deep into the orbit, and this occurs whether the eye is in its natural state or in that of exophthalmus.

Several cases have been reported where there was pulsation of the eyeball itself, synchronous with the beat of the heart. In other cases retrobulbar hemorrhages came on suddenly with marked constitutional symptoms, such as nausea, vomiting, dizziness, and at times coma. The exophthalmus in these cases was attended by great pain; movements of the globe were restricted; the eyeball did not recede when the patient stood upright, and ecchymosis appeared in the lower lid, after a few days, and the globe went back into its normal position, either with normal or restricted vision Such hemorrhages are ascribed to sudden changes in the circulation in the venous system, and to a certain thinning and weakening of the orbital veins and their branches. Neustätter[15] recorded a case in which the exophthalmus, which had been intermittent, became permanent, due to thrombosis of the dilated orbital veins from typhoid fever.

The exophthalmus is limited to one eye, and in the cases reported in the literature, each eye was affected about an equal number of times.

As already mentioned, at the time of the protrusion of the eyeball, in a number of cases, a tumor appears in the orbit, which attains its maximum size when the proptosis is at its height and disappears with the exophthalmus when the conditions which occasion the protrusion of the eye are removed. This tumor varies in size from a pea to a large bean and may occupy any portion of the orbit.

In addition to this class of cases, there is also another, where a tumor appears in some part of the orbit or lid, under the conditions which favor an intermittent exophthalmus and disappears when these conditions are removed. Some of the authors have grouped all three types of cases, i. e., those with exophthalmus without visible tumor, those with exophthalmus and an associated tumor of the orbit, and finally vascular tumors of the orbit without exophthalmus, under the one heading of intermittent exophthalmus; while others have arranged the cases according to the site of the varicose veins in the orbit.

As the genesis of the three classes of cases is the same, and as the presence or absence of exophthalmus or orbital tumor is accidental in any given case, depending

15. Neustätter, O.: Disskuss zu Vosius am. 26 [illegible] Zwei seltene Fälle von orbitaler Krankungen. [illegible] Monatsbl. f. Augenheilkunde, vol. xix, p. 72-75.

on the position of the dilated veins in the orbit, it is impossible to disassociate these groups in describing the disease, though for purposes of classification and description it may be well to do so. Scheffel's classification is as follows:

1. Cases in which the varix is posterior to the globe and there is a simple exophthalmus, either directly forward or with slight lateral deviations.
2. Cases in which the varix is more anterior and may become visible and palpable alongside the eyeball, which has also been proptosed.
3. Cases in which the varix is still more anterior, and where no exophthalmus manifests itself, only the varix appearing.

PATHOLOGY.

As no autopsy has been made on a case of intermittent exophthalmus, it is impossible to assert definitely the pathologic lesion which occasions it, but the clinical symptoms are so striking and so manifestly due to a change in the volume of the veins of the orbit that almost all writers on the subject assign this as the cause of the disease. The structure of the superior ophthalmic vein favors the formation of a varix, for it is without valves and contains a great many constrictions in its course and especially where it empties into the cavernous sinus.

In addition to this, there are certain local conditions which favor a stoppage of the circulation of the blood in the orbit; these have been summarized by Sergent[4] as follows:

1. Anomalies in the bony configuration of the orbit (narrowness of the supraorbital fissure at the point of passage of the veins).
2. Anomalies in the muscles, ligaments and fat bolster of the orbit.
3. Anomalies in the resisting power of the vein walls.

Finally, most authors agree with Sattler that there is an individual predisposition to venous dilatation in many of the cases, as is further evidenced by the varicosities which appear on the face and in other parts of the body in many of them. It has been asserted by a number that a dilatation of the veins alone could not explain the conditions, and they believe that there is in addition a relaxation of the fascia, which holds the globe in the anterior position of the orbit. Van Duyse,[6] Bribos and Terson[16] explain the condition as a trophoneurosis of the orbit as a result of an affection of the sympathetic of the head, and Trombetter,[17] who called particular attention to the facial asymmetry, considers the affection as a commencing and a typical form of hemiatrophia facialis progressiva. Vieussen[18] explained his case by a congenital connection between the arachnoid space and Tenon's capsule, through the medium of the supraorbital fissure. While, as has been stated, in the absence of autopsy it is impossible to do more than hypothesize concerning the origin of the affection, from the clinical manifestations it seems proper to assign the varicosities of the orbit as the primary change and regard the absorption of the fat of the orbit and the looseness of the fascia which occasions, as secondary.

ETIOLOGY AND PATHOGENESIS.

Intermittent exophthalmus may be congenital, or it may develop in childhood; in the great majority of cases, however, it manifests itself at an age when violent physical force is expended and an impediment offered to the ready escape of the blood from the head, with consequent dilatation of the orbital veins. It is probably by reason of the greater physical strain to which men are subjected that the condition occurs more frequently among them than among women; thus, of the 40 cases recorded, about 65 per cent. occurred among men. When women are affected, the period of the appearance of the menses seems to have had a causal connection in a number of instances.

It is often possible to elicit the history of a fall or of a blow on the head, and many authors mention such incidents as etiologic factors, though the length of time which elapses in some of them before the exophthalmus appeared would render such a connection doubtful.

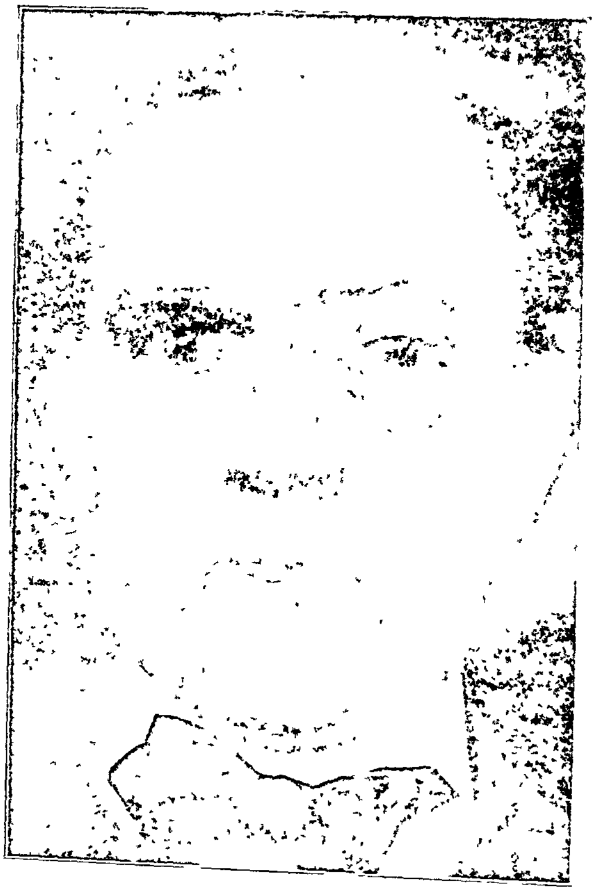

Figure 2.

DIAGNOSIS.

The diagnosis is not difficult, there being no other affection where the exophthalmus appears and disappears so rapidly and under such conditions. Thus intermittent exophthalmus can readily be differentiated from true cavernous tumors of the orbit by the exophthalmus in the latter class of cases persisting when the head is in an upright position, by the occurrence of angiomatous tumors elsewhere in the orbit, by the presence of pulsations and of bruit, and by the slow appearance of the exophthalmus.

The diagnosis, however, from retrobulbar cavernous angioma is not always so readily made, and a number of cases in the literature which have been described as cases of intermittent exophthalmus really belong to this group. Although the exophthalmus may in certain cases of intermittent exophthalmus become permanent (Grüning,[10] Dolgenkow,[19] Van Duyse[6] and Moyart,[20] Hitschmann[13] and Ostrowitski[21]), this is the rule in cavernous tumors; pulsation and bruit are also usually present. Finally, while compression of the jugular in cavernous tumors exerts some influence on the degree of the exophthalmus, it is but slight in comparison with that which follows interference with its circulation in the class of cases under discussion. Intermittent exophthalmus may be differentiated from hemorrhages of the orbit by the history, by the discoloration of the globe and lids, and by the rapid disappearance of the exophthalmus; from emphysema of the orbit after fracture, by crepitation and the relatively rapid healing; from exophthalmic goiter by the other cardinal symptoms of that disease, and by the permanent character of the exophthalmus.

[18] Vieussen: Communication entre le carté arachnoidienne et la capsule de Tenon. Recueil d'Ophthalmol., 1878, p. 314; ref. in Hirschberg's Centralbl. f. Augenheilkunde, 1878, p. 512, und in Nagel's Jahresbericht, 1879, p. 437.

PROGNOSIS.

The prognosis may be stated in general terms to be good, for though the tendency to protrusion of the eyeball may grow more and more marked with advancing years, as the result of a greater dilation of the veins and an increased laxity of the fascia, vision, as a rule. remains unimpaired, no inflammatory symptoms set in and the fellow eye is never affected. As monocular blindness may result from hemorrhage into the orbit or from pressure of the varicosities on the optic nerve, or from hemorrhage into the retina itself, the prognosis, however, should not be too favorable and the possibility of such serious complications should always be borne in mind.

TREATMENT.

The patient should avoid the conditions which cause the eye to proptose and all severe muscular strain should be prohibited; rest in the recumbent or sitting posture should be enjoined, and a bandage should be applied over the affected eye for several hours daily. Though Nélaton obtained a cure by injecting a few drops of the perchlorid of iron into the veins. this procedure can hardly be advised, on account of the danger to provoking thrombosis of the cavernous sinus. The radical healing by extirpation of the mass of veins, as proposed by Chelius, is not without danger, and electropuncture should be first essayed.

In cases uncomplicated by orbital hemorrhage or by visual disturbance, non-operative interference, in our present state of ignorance regarding the pathology of the affection, should be advised, but in cases where hemorrhage has occurred and where the loss of vision is threatened in the affected eye, then. perhaps. Hitschmann's counsel of laying bare and resecting the affected veins should be followed. Krönlein's operation being resorted to if necessary.

A LIST OF ALL TRUE CASES OF INTERMITTENT EXOPHTHALMUS IN THE LITERATURE.

All the authors of whom mention was made in the earlier part of this paper referred to the cases in the literature, and compiled lists of all cases which had appeared up to the time of the publication of their articles, but owing to some difficulty in classification or to a failure to consult the entire literature of this comparatively unknown form of disease, none of the lists is complete. In his final paper Hitschmann gives the most complete list of all. and very properly does not include the cases of varicose veins of the lids or conjunctiva which appear without exophthalmus on stooping, etc., which have been included by Becker[7] and Vossius in their lists. Of the cases cited by him, however, two should be excluded, namely, that of Axenfeld[22] and that of Vossius; that of the former, as it had already been reported by O. Meyers,[23] and that of the latter, as it, too, had already been described. Five additional cases should be added, namely, those reported by Bickerton, Leitner, Lesshoft, Mackenzie, P. Smith, as they are all true instances of intermittent exophthalmus. With these corrections, the list would comprise 39 cases in all, and with the addition of the one I record, 40. After a careful study of all the cases in the literature, I believe the following is a complete list of those who have reported cases of exophthalmus:

1. Becker.[7]
2. Bickerton.
3. *Böhm.*[24]
4. Collins.[11]
5. DeVincentiis.[25]
6. Dolgenkow.[19]
7. Dunkel.[26]
8. *Elschnig.*[27]
9. Gersner.[28]
10. Grüning.[10]
11. *Hitschmann.*[13]
12. Lacompte.[14]
13. Lang.[12]
14. Leitner.
15. Lesshaft.[29]
16. Magnus.[30]
17. L. Mayer.[31]
18. Mackenzie.
19. O. Meyer.[23]
20. Mulder.
21. Neustatter.[15]
22. Ostrowitski.[2]
23. Panas.[5]
24. Posey.
25. Radzwitzky.[32]
26. P. V. Richter.[33]
27. R. Sattler.[9]
28. Scheffel.[8]
29. Schmidt.[34]
30. Schwarzschild.[35]
31. Sergent.[4]
32. Siebold.[36]
33. Terson.[16]
34. Trombetta.[17]
35. Van Duyse and Bribosia[6]
36. *Van Duyse and Moyart.*[20]
37. Van Zanten.
38. Vieusse,[18] and
39. Vossius.

To these 40 typical cases should be added 11 case of venous tumors of the orbit, which behaved like intermittent exophthalmus, but where there was no exophthalmus.[37] These were reported by:

Andræ.[38]
Foucher and Nélaton.[39]
Magel and Bonfon.[40]
Richet.
Chisolm.[41]
Becker.[7]
Denig
Graefe.[42]
Parrish.
Velpeau.
Morgagni.[43]

DISCUSSION

ON PAPERS OF DRS. HANSELL AND POSEY.

Dr. C. R. Holmes, Cincinnati, stated that Mr. Horner, aged 35, in 1892 was treated by him for a chronic catarrhal conjunctivitis. One day Mr. Horner volunteered to give a demonstration, which Dr. Holmes afterwards had him repeat a number of times. Patient stated that this condition had existed for many years and came without any known cause. The eye is rapidly protruded when he holds his breath, stoops forward, or attempts to lift any object from the floor; the ocular conjunctiva becomes congested and the veins of the lids prominent. There is no bruit nor pulsation present, nor could any varix be detected at any point around the globe. Maximum protrusion was about 10 mm. On resuming the erect posture and relaxing the muscles the eye rapidly receded, and there was then, as in nearly all these cases, enophthalmos. The patient stated that he had never suffered any pain, but that when the eye was protruding he experienced a feeling of pressure about the orbit. Ophthalmic examination was negative. Vision equaled 20/20. Dr. Holmes said that the majority of these cases have developed without any known cause, without pain, or any untoward symptom. Some developed in the act of performing labor not at all different from that which they had undertaken hundreds and perhaps thousands of times before and under exactly the same conditions. In Dr. Gruening's case, a man of 45, it came on suddenly, while he was laying a carpet, with a sensation of weight and falling of the eye. On returning to the erect posture the eye returned to normal. In Dr. Elsching's case, a soldier, aged 23, sudden proptosis occurred, with severe pain in the right eye while cleaning his horse. The eye receded on assuming the erect posture. In Dr. Van Santen's case, a woman, 30 years of age, sudden and enormous exophthalmos occurred with hemorrhage into the orbit. The patient had, however, noticed for a year and a half a slight prominence upon stooping. Dr. Holmes stated that the amount of protrusion varies from a very slight prominence to almost complete dislocation of the globe. In Dr. Robert Sattler's case and in Lacompt's case, actual dislocation of the globe took place. That the disease is rare is manifest, as only 40 cases have been reported. Dr. Holmes considers that it is due to a weakening of the coats, and resulting dilatation of the veins, and perhaps of the lymphatics of the orbit, and in the majority of cases causes no serious circulatory disturbances of the globe. It may also be due to a local anatomic defect in the veins and possibly in the muscles, fascia and ligaments of the orbit. Dr. Holmes considers Hugo Sattler's view that there is a predisposition to a general venous dilatation as doubtful, and agrees with Dr. Posey that there must be congenital predisposition of the orbital veins on the affected side favored by the size of the supra-orbital fissure, variations in the valves of the veins and the over or under development of the fascia, muscles, etc. Dr. Holmes considers that it may be readily understood how in some of these cases there is sudden violent attacks of pain with partial immobility of the eye, and at times very severe cerebral symptoms, followed later by hemorrhage and discoloration of the lids—all of which tells very plainly that there is a rupture of the veins with resulting hemorrhage into the orbit, which may or may not lead to choked disc with temporary interference with vision, or permanent atrophy, as in Dr. Meyer's case. The enophthalmos is explained by the atrophy of the orbital contents from pressure.

Dr. J. L. Borsch, Philadelphia, mentioned a case of this kind. The patient, a young woman, consulted him for an exophthalmos, which she said resulted from a severe muscular effort. She had been trying to lift a bureau in her room and immediately experienced a sensation of fullness in her left eye. On looking in the mirror she observed that the eye protruded more than its fellow. At the end of the day the eye assumed its normal position, but would immediately protrude on muscular effort. Dr. Borsch found a venous pulsation in the affected eye—otherwise it was normal; there was no bruit, and vision was normal in both eyes. The patient was quite nervous. Dr. Borsch prescribed tincture of gelsemium and advised prolonged rest in the country. After eight months the condition entirely disappeared.

Dr. G. E. Seaman, Milwaukee, Wis., stated that he has come in contact with four cases of pulsating exophthalmos from injury, fractures of the skull. All four were operated on by ligation of the common carotid, and in three a good result was obtained. In the fourth case, which he saw only incidentally, there was an enormous exophthalmos, the symptoms were very pressing and the eye was removed and the orbit packed, but the hemorrhage immediately following was so severe that an immediate operation, ligation of the common carotid, was done. Almost immediately following this there was a complete hemiplegia of the opposite side, which has persisted to this day, although the operation was several years ago.

Dr. W. H. Wilder, Chicago, referred to three cases of pulsating exophthalmos. One of these was particularly interesting, because the only cause that could be assigned for it was syphilis—fifteen years previously; the pulsating exophthalmos came on suddenly without any traumatism. It was suspected that there was an arteriovenous aneurism as a result of

group. Although the exophthalmus may in certain cases of intermittent exophthalmus become permanent (Grüning,[10] Dolgenkow,[19] Van Duyse[6] and Moyart,[20] Hitschmann[13] and Ostrowitski[21]), this is the rule in cavernous tumors; pulsation and bruit are also usually present. Finally, while compression of the jugular in cavernous tumors exerts some influence on the degree of the exophthalmus, it is but slight in comparison with that which follows interference with its circulation in the class of cases under discussion. Intermittent exophthalmus may be differentiated from hemorrhages of the orbit by the history, by the discoloration of the globe and lids, and by the rapid disappearance of the exophthalmus; from emphysema of the orbit after fracture, by crepitation and the relatively rapid healing; from exophthalmic goiter by the other cardinal symptoms of that disease, and by the permanent character of the exophthalmus.

PROGNOSIS.

The prognosis may be stated in general terms to be good, for though the tendency to protrusion of the eyeball may grow more and more marked with advancing years, as the result of a greater dilation of the veins and an increased laxity of the fascia, vision, as a rule, remains unimpaired, no inflammatory symptoms set in and the fellow eye is never affected. As monocular blindness may result from hemorrhage into the orbit or from pressure of the varicosities *on the optic* nerve, or from hemorrhage into the retina itself, the prognosis, however, should not be too favorable and the possibility of such serious complications should always be borne in mind.

TREATMENT.

The patient should avoid the conditions which cause the eye to proptose and all severe muscular strain should be prohibited; rest in the recumbent or sitting posture should be enjoined, and a bandage should be applied over the affected eye for several hours daily. Though Nélaton obtained a cure by injecting a few drops of the perchlorid of iron into the veins, this procedure can hardly be advised, on account of the danger to provoking thrombosis of the cavernous sinus. The radical healing by extirpation of the mass of veins, as proposed by Chelius, is not without danger, and electropuncture should be first essayed.

In cases uncomplicated by orbital hemorrhage or by visual disturbance, non-operative interference, in our present state of ignorance regarding the pathology of the affection, should be advised, but in cases where hemorrhage has occurred and where the loss of vision is threatened in the affected eye, then, perhaps, Hitschmann's counsel of laying bare and resecting the affected veins should be followed. Krönlein's operation being resorted to if necessary.

A LIST OF ALL TRUE CASES OF INTERMITTENT EXOPHTHALMUS IN THE LITERATURE.

All the authors of whom mention was made in the earlier part of this paper referred to the cases in the literature, and compiled lists of all cases which had appeared up to the time of the publication of their articles, but owing to some difficulty in classification or to a failure to consult the entire literature of this comparatively unknown form of disease, none of the lists is complete. In his final paper Hitschmann gives the most complete list of all, and very properly does not include the cases of varicose veins of the lids or conjunctiva which appear without exophthalmus on stooping, etc., which have been included by Becker[7] and Vossius in their lists. Of the cases cited by him, however, two should be excluded, namely, that of Axenfeld[22] and that of Vossius; that of the former, as it had already been reported by O. Meyers,[23] and that of the latter, as it, too, had already been described. Five additional cases should be added, namely, those reported by Bickerton, Leitner, Lesshoft, Mackenzie, P. Smith, as they are all true instances of intermittent exophthalmus. With these corrections, the list would comprise 39 cases in all, and with the addition of the one I record, 40. After a careful study of all the cases in the literature, I believe the following is a complete list of those who have reported cases of exophthalmus:

1. Becker.[7]
2. Bickerton.
3. Böhm.[24]
4. Collins.[11]
5. DeVincentiis.[25]
6. Dolgenkow.[19]
7. Dunkel.[26]
8. Elschnig.[27]
9. Gersner.[28]
10. Grüning.[10]
11. Hitschmann.[13]
12. *Lacompte.*[14]
13. Lang.[12]
14. Leitner.
15. *Lesshaft.*[29]
16. Magnus.[30]
17. L. Mayer.[31]
18. Mackenzie.
19. O. Meyer.[23]
20. Mulder.
21. Neustatter.[15]
22. Ostrowitski.[3]
23. Panas.[5]
24. Posey.
25. *Radzwitzky.*[32]
26. P. V. Richter.[33]
27. R. Sattler.[9]
28. Scheffel.[8]
29. Schmidt.[34]
30. Schwarzschild.[35]
31. Sergent.[4]
32. Siebold.[36]
33. Terson.[16]
34. Trombetta.[17]
35. Van Duyse and Bribosia[4]
36. Van Duyse and Moyart.[20]
37. Van Zanten.
38. Vieusse,[18] and
39. Vossius.

To these 40 typical cases should be added 11 cases of venous tumors of the orbit, which behaved like intermittent exophthalmus, but where there was no exophthalmus.[37] These were reported by:

Andræ.[38]
Foucher and Nélaton.[39]
Magel and Bonfon.[40]
Richet.
Chisolm.[41]
Becker.[7]
Denig
Graefe.[42]
Parrish.
Velpeau.
Morgagni.[43]

The medical treatment was chiefly nitrate of silver and extract of belladonna; five drops of the saturated solution of potassium iodid was administered at various times, but was badly borne, and after two or three days' trial had to be given up. Extract of opium and antipyrin were used to relieve the pain.

Subsequent History.—After nearly three years of usefulness he returned to Philadelphia with similar symptoms and was put to bed as before under my care in the Presbyterian Hospital. The gastric crises were very distressing and he was reduced to 104 pounds. Under treatment he again improved, and at the end of nine weeks he had risen in weight from 104 to 150 pounds. The same inability to take iodids was noted and the same improvement under nitrate of silver and belladonna was observed in connection with the treatment. Mercuric chlorid, 1/20 gr. twice daily, was administered hypodermically for 5 weeks.

There were no febrile crises in this case. The object in citing so typical a case is to emphasize the great advantage in carrying out the rest treatment in these cases. They should be taken off their feet before they weary themselves by wandering around the streets unconscious of the ordinary sense of muscular fatigue. Massage and electricity supply all the needs of exercise. The faradic or the sinusoidal form of faradic electricity is probably the best for these cases. As they gain flesh and strength, graduated educational exercises should be employed and are very easily carried out. In this case faradism was applied by a rectal electrode for a few minutes daily to relieve the atony and anesthesia of the rectum and anus. This was a trying symptom and gas escaped when it was impossible for the patient to control it. It was not considered necessary in this case to use lavage. The vomiting ceased under the use of a pepsin preparation, with phenacetin and deodorized tincture of opium. How long an interval may be expected before the patient reverts to the unfortunate condition in which I found him, it is impossible to tell. A quiescent period of two or three years is, of course, a great gain, and I have ventured to cite his history to encourage others to confidently treat these cases along similar lines, even in the face of such frightful symptoms as this man presented.

IMMUNITY.

CHAPTER IV—Concluded.

Micro-organisms.

The belief that invisible "animalcules" were able to cause morbid processes in man is a very old one. A passage from Varro (116-27 B. C.) reads as follows: "There are swampy places in which grow animals never so small which may not be recognized by the naked eye, and through the air gain access to the body and bring about severe diseases."

The Microscope.

The discovery and use of the compound microscope in the seventeenth century disclosed the reality of the minute living forms which had been so often suspected. Kircher, with his first crude microscope (1646), examined the tissues of various diseases, and was the prolific author of many theories as to their etiology. It is now believed that the magnification of Kircher's microscope was so small that many of the "worms" which he saw were really larger fungus cells and in some instances the as yet undiscovered blood and pus cells.

Leeuwenhoek, with his compound microscope, magnifying 1,000 diameters, described accurately many microscopic forms, but made no application of his discoveries to medical problems. Such application was by no means wanting, however, and the succeeding century and a half saw such voluminous descriptions of microbes, so many contradictory theories and statements, that the "infinitesimally small" fell into disfavor in many quarters as the cause of diseases. The attractions and reasonableness of the theory, however, were such that it continued to gain exponents, and in the early part of the nineteenth century reached a degree of definiteness. In 1855, the great French physician, Brétonneau, affirmed that a specific germ was the cause of every contagious disease. "An epidemic disease can originate and extend only through the agency of the germ producing it." Yet at this time no infection had been proved to be of microbic origin.

Anthrax.

In 1850 Rayer and Devaine made an observation, which probably would have fallen into the oblivion of many preceding ones had it not been confirmed by later observations of importance. They found "small filiform bodies" in the blood of sheep which had died of anthrax, and were naturally inclined to believe that these forms caused the disease. Other students, especially Pasteur and Koch, soon took up the study its [illegible] disease with the result that the small rods of Devaine cular eff[illegible]entifically proved to be its cause.

eye—other [illegible]t minds dominated medical research at this time was normal [illegible]nd Koch. Pasteur, in his early career as a Borsch prescrib chemist, had had his attention called to the rest in the cou. processes of fermentation. He recurred to disappeared. this subject at a time when the theory of

Dr. G. E. Sous generation of small living forms was widely in contact [illegible]d in 1857-1861 proved beyond any possibility injury, fract[illegible] lactic acid, alcoholic and butyric acid fermenligation of t[illegible] due to the action of minute living cells; and, obtained. [illegible], that each particular kind of fermentation had its there was a[illegible] microbe as the cause. This was an example very press[illegible]ve term to-day microbic specificity. Pasteur then but the [illegible]hat he had learned about fermentations to the that an i study of the diseases of wines and beers. was done. He found their causes, and devised a preplete henry. ventive measure, which consisted merely in day, alth the application of the proper degree of heat

Dr. W[illegible]ine before it was stored. At the instance of the sating e[illegible]government, he then studied certain diseases of silking, beca His success in discovering their causes and prevensyphilis-[illegible]t always remain for us one of the landmarks of the came on progress. It was at this time that he took up the that th[illegible] anthrax. The specific microbe having been discovered, and the methods of transmission of the malady made clear, he turned his attention to methods of prevention and, if possible, of cure.

Vaccination.

Anthrax.

Hydrophobia.

Pasteur pondered the question of smallpox vaccination. He came to believe that varioloid was smallpox, the virus of which had been attenuated by its passage through the cow, and that consequently when man was vaccinated he was inoculated with a benign form of the disease. Might not this be an example of a law which would be general in its application? The protective inoculation (active immunization) against the pleuropneumonia of cattle which had long been practiced gave encouragement to this hope. Some work by Toussaint was important in the answer to this question. It was evident that a weakening or attenuation of the bacteria or virus must first be obtained before it could be safely injected into animals for the purpose of producing immunity. Accordingly, Toussaint heated virulent anthrax blood to a temperature of 55 degrees C. for ten minutes and injected the product into a number of sheep. Some animals died of anthrax, while others suffered only a mild attack from which they recovered; the latter were found to be immune to a subsequent inoculation with virulent blood. Inasmuch, however, as some of Toussaint's animals had died of anthrax, Pasteur concluded that there was some grave error in technic. He considered that Toussaint's method probably killed or attenuated the fully-developed bacilli, but did not injure the spores of the parasite (Koch had previously shown the existence of anthrax spores). After much experimentation, Pasteur hit on the plan of growing the bacillus at a temperature of 42 degrees C., obtaining in this way a culture of the fully developed organism which had a low virulence, but which did not form the dangerous spores. When sheep were inoculated with the proper amount of this culture, which became known as anthrax vaccine, they had a mild attack of the disease, which rendered them immune to virulent inoculations. With the possibility of protective inoculation with a known virus actually demonstrated, similar procedures were tried with other animal diseases of known bacterial etiology, with the result that successful vaccines against chicken cholera and swine plague were developed. Pasteur and his co-workers having failed to discover the microbes of plague and cholera, soon turned to the study of another disease which not only destroys many domestic animals, but is at the same time one of the most dreaded diseases which attack man, hydrophobia. All efforts to cultivate the virus from the spinal cord of rabid dogs, which surely is its seat in the affected animal, failed. The unique idea then occurred to consider the infected spinal cord as a fully developed culture of the virus. It remained to subject such a culture to the proper attenuating conditions to weaken or actually to destroy its virulence in order to make it fit for protective injections. This was accomplished by drying the cords in a closed vessel over a hygroscopic substance (solid potassium hydroxid), the final virulence of the cord depending on the length of time it had been subjected to the drying process. The technic of the protective injections, the success of which is household knowledge, will be the subject of later consideration.

Two Important Principles.

By no means of secondary importance, during this period, was the work of Koch on the specific bacteria of tuberculosis, cholera, typhoid and the pyogenic diseases; and not least his improved methods of obtaining pure cultures through the use of solid media (gelatin) on plates. Through his work and that of Pasteur two great principles had been set in motion: the microbic specificity of infectious diseases, and protective inoculation in its generalized form, through the use of attenuated virus.

Theories of the Cause of Immunity.

Exhaustion Theory.

The scientific mind turned at once to the inquiry, What changes take place in an animal's body as the result of the protective inoculation, which render it immune to an infection to which it was formerly susceptible (acquired immunity)? And again, what properties of the tissues or body fluids render one type of animal immune to an infection while another species is subject to attacks of this disease (natural immunity)? Pasteur had observed that if he grew the microbe of chicken cholera in a liquid medium for some time, then removed the bacteria by filtration, the fluid became unfit for the further growth of the organism on subsequent reinoculation. That is, the nutrient material had been used up; and he suggested that this is the case in the animal body. Having undergone the infection, suitable nutrient material for the microbe is used up, and the patient recovers. The disappearance of the proper nutritious substances is assumed to be more or less permanent and consequently renders the animals immune to further attacks. This conception, the exhaustion theory, at one time shared by Koch and Klebs, is still represented in an altered form by Baumgarten, who speaks of an unfavorable culture medium as representing the condition of the immune body, which, of course, is broadly true.

Noxious Retention Theory.

Chauveau was the author of another historic theory of acquired immunity (the noxious retention theory), which was to the effect that during the course of a disease the bacteria produced substances in the presence of which they could not develop further; consequently recovery took place, and the continued presence of these noxious substances made another attack of the disease impossible. Although it is true that bacteria do not grow well in their own metabolic products, theories of immunity on this and similar bases are not in accord with the fact that immunity may be of great duration, and that it may be conferred by the injection of the killed bacteria, or, in some cases, of their non-living soluble products.

Phagocytosis.

Metchnikoff may be credited with having first offered a plausible explanation of natural resistance, founded on observation. As a zoologist he had studied the subject of intracellular digestion in the lower animals, and it was while working on this problem that he observed the fate of a yeast fungus (*Monospora*), which caused epidemics among the daphnia, small, transparent animals with which he was working. In the alimentary tract, which was the infection atrium, some large mesoblastic cells, which are perhaps analogous to the white blood cells, were seen to ingest the parasites and dissolve them. If this took place to a sufficient extent the animals recovered; if, however, the infecting organisms were too numerous or the reaction on the part of the animal insufficient, the body became overwhelmed with parasites and death resulted. Since that time Metchnikoff has evolved his well known theory of phagocytosis as the essential factor in both natural and acquired immunity, a theory which Pasteur, in his later years, looked on with favor. We may speak of this as the cellular theory of immunity; a theory which has had to undergo important modifications in order to bring it into accord with new facts.

Investigations of the Properties of Serums.

Bactericidal Power.

Considering that natural or acquired immunity must exist because of certain qualities of the body cells, or of the body fluids, or possibly of both, investigators began to make analyses of the tissues; and of all the analyses, that which we may term the biologic has been the most fruitful. In this case biologic analysis means the determination of reactions which may occur when bacteria or their products are placed in contact with tissue cells or fluids. The chief of these are the determination of the ability of the serum of an animal to kill bacteria or to neutralize bacterial toxins. These important investigations, still in their infancy, were inaugurated by the findings of Fodor, Nuttall, Nissen, v. Behring and Buchner.

showed that fresh defibrinated blood, and the blood serum of various animals, were able to kill bacteria in the reagent glass. In contrast to the action of ordinary antiseptics, this power is often selective, killing one variety of bacterium and leaving another unharmed. This is of enormous importance, as it would seem to identify the factor on which natural immunity depends. Then followed the discovery of Nissen and v. Behring (*Vibrio metchnikovi*) and of Bouchard (*B. pyocyaneus*), that if an animal is systematically injected, i. e., immunized, with a micro-organism, the power of its serum to kill the bacterium used in the immunization is greatly increased; from which it would seem that acquired immunity depends on the increase of powers which are normally present to a certain degree. These phenomena have to do with the antibacterial or bactericidal power of serum.

Toxins and Antitoxins.

It was a most important step when it was found that the tetanus bacillus (Brieger and Fränkel) and the diphtheria bacillus (Roux and Yersin) secrete each a powerful, specific, soluble toxin, which may be separated from the bacteria by filtration. Immunization with these bacterium-free toxins was undertaken (Behring and Kitasato) with the familiar result of the production of the specific antitoxins.

With these facts in hand, the vigor with which investigations have been pushed may be readily imagined. The hope naturally prevailed that physicians might become the masters of all infectious diseases, through the possession of specific antibacterial and antitoxic serums. But failures, with which we are only too familiar, met the attempts to produce adequate antitoxins for many diseases. Nevertheless, these failures have stimulated investigators to a closer study of various aspects of immunity and the methods by which bacteria cause disease. This has resulted in the acquiring of much knowledge concerning the properties of bacteria, toxins and the immune serums, out of which has grown a new theory of immunity, the "side-chain" theory of Ehrlich.

(*To be continued.*)

Clinical Report.

EXTENSIVE INJURY TO THE SKULL AND BRAIN, PATIENT LIVING NINE DAYS.

EVERETT MINGUS, M.D.
MARSHFIELD, ORE.

I am indebted to Walter Culin, M.D., Coquille, Ore., in whose practice it occurred, for the report of the following case.

I was called August 26 to see a man five miles in the country who had been struck on the head, while working in a logging camp, by an iron hook attached to a heavy chain, the whole weighing about 75 pounds. The accident was occasioned by the hook suddenly giving way while strong traction was being made on it in the direction of the injured person, by a steam engine.

Examination.—On reaching the patient I found an extensive laceration of the scalp covering the left frontal region and brain matter oozing from the wound. A considerable piece of the frontal bone was gone from over the eye. This piece of bone measured 1¼ by 1¾ inches and was lying on the ground some ten feet away from the place where the man was injured. There was also a compound depressed fracture over the anterior superior angle of the left parietal bone. The condition of the patient was that of impending death. Pulse 180, small and thready; Cheyne-Stokes respiration; cold extremities; subnormal temperature and clammy skin. There was injury to the teeth and tongue and escape of blood from the mouth and nose. The scalp wound over the eye extended downward across the inner canthus and involved the lower lid of the left eye. The eyeball was intact but cloudy, and there were signs of interocular hemorrhage. The right eye was unimpaired; the pupil was normal and responded to light. No paralysis of extremities. He passed urine voluntarily and controlled rectal evacuations. Hearing in both ears was normal. Patient was somewhat restless, but obeyed orders from attendants.

Treatment.—In view of the hourly expectation of his death, the extensive nature of his injury, and unfavorable surroundings, nothing was done to the wound with the exception of inserting a few provisional stitches and applying a light dressing.

Subsequent History.—Toward morning of the next day the patient's condition showed improvement, and by 2 p. m., 21 hours after receiving the injury, his pulse fell to 85; temperature, 98.5; respiration, 26, and regular. He responded "yes" and "no" to questions promptly. No vomiting. August 28: Pulse, 85, full and regular; temperature, 100; respiration, 26, and regular. Mental condition unchanged. Tongue swollen and protruding slightly between the teeth. No vomiting. No paralysis of face or of other groups of muscles. No twitching; sensation normal; reflexes intact. August 29: Pulse, 85, full and regular; respiration, 20 and regular; temperature, 100. The wound over the orbit was opened and a considerable mass of protruding brain substance in a necrotic condition was removed by gentle irrigation and sponging. During these manipulations a large blood clot plugging the superior longitudinal sinus became loose, which prohibited further work in that neighborhood. Irritation of the brain substance over the injured area did *not* elicit *any* response, while the same degree of irritation applied to the membranes or skin would cause him to wince his face and raise his hand for protection. He complained of headache. He took 12 ounces of liquid nourishment at one feeding. *August 30:* No change. He took nourishment freely and attempted to explain his feelings, but articulated with difficulty, which was apparently due to injury to his tongue. Edema about right eye and wound is disappearing. He recognizes his friends and calls them by name indistinctly. Says he feels very good with the exception of headache. August 31: No change from previous day. Scalp wounds uniting and swelling about left eye going down. September 1: Pulse, 85; temperature, 100; respiration, 20. He took a newspaper in his hand, read for a half-hour with apparent interest. September 2: Pulse, 120; temperature, 98; respiration, 20. No other change from previous day. September 3: Pulse, 140 and regular; temperature, 100; respiration, 26. September 4: Pulse, 144, irregular and dicrotic; temperature, 99; respiration, 30. Died at 2 p. m. without manifesting any cerebral symptoms.

Autopsy.—An irregular wound of the skin beginning on lower eyelid on left side, thence across inner canthus to the root of the nose, thence upward and outward over the frontal bone to a point corresponding to the beginning of the temporal ridge. A second wound on the left side four inches in length, just behind and parallel to the coronal suture.

Cranium: Two compound comminuted depressed fractures united by a linear fracture. The first and most serious involved the vertical portion of the frontal, orbital ridge, anterior three-fourths of the orbital roof, great wing of the sphenoid, nasal bones, horizontal plate and crista galli of the ethmoid; the second was situated just behind the coronal suture, of irregular outline and one inch square. From it extended a linear fracture into the first one and also one passing over the top of the skull into the right parietal bone for a distance of one and a half inches. The spiculæ of bone from this fracture were driven well into the brain substance.

Brain: Complete destruction of the left frontal lobe. The posterior line of injury passed through the precentral fissure downward and forward, skirting over the ascending and horizontal branches of the anterior limb of the Sylvian fissure. On the basal surface the destruction extended as far back as the middle of the olfactory bulb and on the mesial surface as far as the genu. The superior longitudinal sinus was torn across and thrombosed to a point opposite the coronal suture. The substance of the brain in the injured area was pulpified to such a degree that it could be removed by gentle sponging. The peculiar interest in this case is the survival of the initial shock and the complete absence of sensory, motor and psychical symptoms.

BREWER'S YEAST FOR PYOGENIC INFECTIONS.

It is stated that the workers in some breweries in France have for many years made use of brewer's yeast in the treatment of acne, furunculosis and malignant pustules. The first mention of this remedy in medical literature is by Mosse, in 1852. Brocq claims that he used yeast on himself in the treatment of recurrent malignant pustules, and was entirely cured, although he had tried many other remedies without obtaining relief. He reports in detail one other case of malignant pustules, three cases of furunculosis and one case of acne, all of which it is alleged were cured with brewer's yeast. Lassar used it in the treatment of furunculosis complicating diabetes, and reports equally satisfactory results. Many other reports may be found in the recent literature, nearly all of which speak highly of this simple remedy. The best results are obtained with fresh brewer's yeast (*Saccharomyces cerevisiæ*), although baker's yeast has also been used. It is taken internally in doses of from a teaspoonful to a dessertspoonful dissolved in a glass of water. This may be drunk during or at the beginning of each meal, three times a day. It is important that the yeast should be fresh, because slight digestive disturbances, and occasionally diarrhea, are produced even by perfectly fresh yeast.

Recently yeast has been locally applied in the treatment of gonorrheal affections in women. It has been used in the form of balls which are introduced into the vagina and also in the form of suppositories which are introduced into the cervix. Some very satisfactory results have been reported from this treatment by Abraham[1] and others. Cronbach,[2] however, does not think that it has any great advantage over the older treatment with antiseptics.

The exact mode of action of this remedy is not clearly understood, although several attempts have been made to throw light on this question by test-tube and animal experiments. Sergent inoculated rabbits with staphylococcus aureus by rubbing the cultures into the shaved skin. This inoculation produced many small furuncles, which healed rapidly under the administration of yeast. The controls always required from four to five days longer for recovery. When large doses of staphylococcus were injected under the skin the rabbits invariably died from the infection. McNair Scott could not notice any difference in favor of the treated rabbits when observing a large number of animals that had been inoculated with staphylococcus. Turro, Tarruella and Presta[3] inoculated six rabbits under the skin of the ear with several drops of a virulent streptococcus. Four of these rabbits were treated with yeast by subcutaneous injections, and the other two got no treatment. All of the animals developed erysipelas of the ear, but those that were treated soon improved and were practically well on the seventh day, while both controls were still becoming worse. One of the controls showed signs of improvement on the tenth day, and made a slow recovery, but the other died of a generalized infection on the eleventh day. Somewhat similar results were obtained from inoculation with *Staphylococcus pyogenes aureus* and *albus*. These investigators, as well as Sergent, were able to produce a fair degree of immunity in rabbits to the pyogenic micrococci, by treating the animals with yeast for a number of days before the inoculation. This immunity, however, was soon lost after discontinuation of the treatment. The serum of animals thus treated acquired high agglutinative properties for streptococci and staphylococci, but was not bactericidal. Extract of yeast cells has not given as satisfactory results as the whole yeast. It would seem from these reports that the administration of yeast has a favorable influence over many mild forms of pyogenic infection, and as it is a very simple and harmless remedy its use can be safely recommended.

WATER DRINKING INDICATIONS AND CONTRA-INDICATIONS.

It is well known that artificial, dry heat causes evaporation of moisture from the bindings of books and from joints of furniture, etc. That it should also cause increased surface evaporation in human beings is not surprising. Hence the necessity for drinking water at intervals during the day, especially for those in whom a certain amount of constipation with a tendency to hard stools shows that there is a diminished amount of water in the system, and that nature is only with difficulty able to carry on certain of her functions requiring water.

As the result of the successful employment of water to relieve many ordinary symptoms, it has become the custom to recommend water very generally and sometimes without sufficient deliberation. For the comparatively well, who need only to supply an equivalent for the moisture that is being lost—particularly through the skin and the lungs—the simple advice to drink plentifully of water is almost sure to be good. In many diseases, moreover, the ingestion of water is an efficient aid to other treatment. For example, in bronchitis, especially if the accompanying cough be hard and ineffective, the taking of large amounts of fluid is usually productive of good results. In fact, it is on this therapeutic principle that the reputation acquired by many of the old home remedies depends. A warm drink taken just before going to bed will often keep a patient from being annoyed by a cough during the night.

[3] Centralbl. f. Bakt., 1903, vol. xxxiv, p. 22.

On the other hand, to recommend abundant drinking of water may be, for patients suffering with some diseases, decidedly poor advice. For example, in the case of cardiac affections with failing compensation, the necessity for an already weakened heart to overcome the resistance of a large amount of fluid in the circulation is certain to invite further deterioration of the heart muscle. One of the well-known and very serious forms of heart disease is the degenerative type which occurs in connection with the drinking of large quantities of such liquors as beer; the result is degeneration of the heart muscle and an extensive dilatation of the heart on account of overwork. It is easy to understand that a large amount of even so innocuous a fluid as water would tend to produce similar results. Whenever, then, there is loss of compensation in a heart that is laboring under some valvular defect, or under some degenerative process, the advice to drink plenty of water should be given with caution.

There is one class of cases, however, in which the unfortunately common custom of recommending the liberal drinking of water is likely to prove even more harmful than in heart disease. The first recommendation that too many physicians make to a patient suffering from almost any form of nephritis, unless there is marked ascites present, is to drink water abundantly. The idea is that in this way the system will be thoroughly "flushed out" and that the toxins in the circulation which may injure the kidneys will be diluted and made less harmful. The exclusive milk diet so often suggested for nephritis is really one expression of this old tradition. It must be remembered, however, that the value of this old-time advice lacks confirmation. Professor von Noorden, in his monograph on nephritis, has particularly insisted on the fact that this advice is often fruitful of more harm than good. In the American edition of his work on nephritis he says that water is always very badly excreted by the kidneys when they are *acutely* diseased, and frequently also in subacute and in subchronic forms of nephritis, though individual cases differ greatly in this respect. He insists that the only possible way to determine whether water, which is in many cases one of the best diuretics we have, is indicated or not, is to determine whether the output of water bears a definite relation to the amount ingested. He adds: "A condition of hydremia must be regarded as a *constant* source of irritation of the kidneys, and the problem that confronts us is to prevent excessive stimulation of these organs as much as possible."

It is evident, therefore, that water drinking, usually a physiologic, a hygienic and a remedial procedure of great value, in special cases may be attended with harm, and that the physician's advice to individuals should be given with reference to the particular case under consideration.

TUMORS OF THE CAROTID GLAND.

For complete obscurity of purpose there is no organ in the body that surpasses, in our present state of knowledge, the carotid gland. The sum total of information concerning its function may be considered as zero. Concerning its structure we are much better informed, thanks particularly to Marchand. Situated in or a trifle behind the bifurcation of the carotid, its greatest dimensions usually are between two and four millimeters, or about the size and shape of a kernel of rice, but it may be much smaller, and, according to some writers, it may be impossible to find it on one or both sides. It is most intimately connected with the sheath of the carotid artery, from which it appears to be developed, appearing rather early and reaching its maximum size in the sixth month of fetal life. Structurally, it is quite vascular, consisting largely of glomerular tufts of small vessels, surrounded by considerable numbers of cells of a distinctly endothelial type derived from the perivascular endothelial structures of the carotid. Such a structure hardly seems to indicate any considerable secretory activity, for the amount of cellular protoplasm is not such as we usually associate with glandular action, although the large number of vessels might lead to a different conclusion. Probably on account of their extremely small size, and a location that renders them practically unavailable for experimental studies, little seems to have been learned about them by the physiologists.

Pathologically, however, they are of interest as the possible starting point for tumor growth, and these tumors present particularly interesting problems to the surgeon. Although the literature contains only about a score of reported cases, yet there is every reason to believe that they are much more frequent than has been generally appreciated. During the past two years, since the special features of these growths have become a little more known, more cases have been reported than can be found in the entire literature before this period. In 1888, Jonathan Hutchinson described them well under the name of "Potato Tumors of the Neck," because of their shape, and brought out their chief characteristics: the location under the sterno-mastoid, the solitary nature, the potato- or kidney-like shape with frequent nodosities, the entirely local nature of the growth, occurrence particularly in men past middle life, and fatal termination usually in from one year to eighteen months. He mentions having seen at least eight cases up to that time. It is only within a very recent time that we have had any general understanding of the characteristics of endothelial tumors, to which these tumors of the carotid gland belong, and this fact accounts for many of the failures to recognize the nature of the growths when they have been removed by surgeons; they can easily be mistaken for hyperplastic or lymphomatous glands in some cases, for sarcomatous glands in others, and even for carcinoma arising in branchial remains. Whenever a surgeon meets a solitary growth arising in close relation with the bifurcation of the carotid, in which it often lies, "like a meal sack," he should consider the possibility of a tumor of the carotid gland. In common with endothelial growths of different origin, these tumors seem to vary greatly in their degree of malignancy. Hutchinson speaks of a fatal occurrence as usual in from twelve to eighteen months, but, on the other hand, many of the reported cases seem to pursue a comparatively benign course; recently, indeed, certain French writers, after a review of the literature, questioned the advisability of operation in view of this apparent benignancy. Because of the intimate relation of the growth with the carotids, it is often impossible to remove it without ligation and resection of the common carotid, a procedure of no inconsiderable danger at the advanced age at which it usually occurs. Even where resection without ligation of the carotid is possible, its advisability is questionable in view of the possibility of recurrence in the carotid sheath within which the tumor originates. Gilford and Davis[1] report three typical and instructive cases which they have observed. In one, the common carotid was ligated and resected with the tumor; hemiplegia resulted and death from pneumonia followed in seven days. In the second case, the tumor was dissected away from the arteries, but in six weeks recurrence in the scar was observed, the growth developing rapidly, ulcerating, and causing death in five months. The third was inoperable, and was unique in being bilateral and in producing metastases in the liver; the patient, a man of 74, died from exhaustion eighteen months after the first appearance of the growth. Here we have illustrated three possible courses for the surgeon, but all failed to save the patient.

It is evidently, in view of these facts, extremely difficult to decide on the proper course of procedure in these cases. Operation is evidently hazardous; non-interference in some cases may be preferable, but in which cases will the growth be malignant and in which benign? Hence it is of the utmost importance that these peculiar tumors should be recognized as entirely different from all other growths arising in the neck, and that every case should be carefully studied and reported until the proper course of management can be determined; a thing now impossible because of our scanty information.

TRUTH AND POETRY CONCERNING URIC ACID.

VI.

Slowly but surely, as we have seen, the truth concerning the formation of uric acid in the body was being found out. An origin from the metabolism of the nuclein of the body cells had been established; the possibility of the formation of uric acid directly from the nucleins or xanthin bases of the foods had been definitely demonstrated; and, as was hinted in the concluding paragraph of our last article, the possibility of a third mode of formation, namely, through synthesis of simpler chemical compounds, began to be considered.

Efforts to solve the problem as to whether or not synthetic formation of uric acid occurs in the body were made in various ways. Some tried to increase uric-acid excretion by feeding substances from which uric acid can be manufactured synthetically outside the body; others by feeding substances which are known to be derived from the decomposition of uric acid within the organism. The earlier experiments of this sort were negative. Horbaczewski, in 1882, tried feeding experiments with glycocoll, but got no marked increase in uric-acid excretion; a similar experiment by Weiss, in 1899, yielded negative results. Minkowski, in 1898, fed lactic acid and urea to dogs in the hope that these bodies might be synthesized to uric acid, but without obvious success. He was led to try the experiment by the fact that in birds from which the liver has been extirpated, the uric acid of the urine is replaced by lactate of ammonia, and, beside, Horbaczewski had synthesized uric acid *in vitro* from trichlorlactic acid and urea. Nor were experiments in which men were fed with these substances more successful (Hermann, 1888; Weiss, 1898).

Despite the discouraging influence of these early attempts at intracorporeal synthesis of uric acid, investigators continued to hope that the proof of the synthetic formation might yet be shown. This hope was fostered by a group of facts which made it seem improbable that the total formation of uric acid in the body can be accounted for without synthesis. Thus it had been shown that the feeding of glycerin increases the amount of uric acid excreted, and some feeding experiments made with fats and carbohydrates pointed to the probable synthetic formation of uric acid, under certain circumstances. The studies of Hopkins and Hope, in 1898, indicated that the excretion of uric acid after meat-eating occurs earlier and ceases sooner than that of other nitrogen compounds. The increase occurs too quickly to be accounted for by the absorption of nuclein, and, further, is not due to sudden excretion dependent on removal of preformed uric acid rendered more soluble. They thought, therefore, that some substance in meat, which can increase the excretion of uric acid, is absorbed by the stomach. Again, in 1899, Wiener showed the capacity of isolated organs to synthesize uric acid. Thus the isolated liver of animals is capable of manufacturing uric acid from an alcoholic extract of various organs, even when this extract is free from nuclein and xanthin bases.

---

[1] The Practitioner, 1904, p. 729.

It was to comparative physiology, however, that investigators had to turn for help, in connection with the synthesis of uric acid in the animal body. It had long been known that certain animals, like birds and reptiles, excrete most of their nitrogen not as urea, as in mammals, but as uric acid. In these animals the amount of uric acid excreted varies with the amount of food ingested. It sinks in inanition; it is increased in all conditions which augment proteid metabolism. Substances which, when fed to mammals, are oxidized to urea are excreted in birds as uric acid. All these facts indicated that in birds and reptiles synthesis plays an important rôle in uric-acid formation.

A very important publication was made on this subject in 1886 by Minkowski.[1] This investigator, on extirpating the livers of birds, found that the nitrogen of the urine was present as ammonia, not as uric acid. And since ammonium lactate was present in the urine, he thought it probable that ammonia and lactic acid are important forestages in uric-acid synthesis, and that this synthesis is effected in the liver in birds. The idea soon gained ground that in the synthesis of uric acid two molecules of urea unite with some atom complex containing three carbon atoms, but no nitrogen. Minkowski thought that this non-nitrogenous atom complex is furnished by lactic acid, and his view received some support through the facts that the feeding of lactic acid to birds increases uric-acid excretion (Wiener, 1902), and that when lactic acid is passed through the isolated bird's liver uric acid is formed from it (Kowalewski and Salaskin, 1901).

In view of the high degree of probability that lactic acid takes part in the synthesis of uric acid in birds, it became important that the process should be more closely examined with special reference to its exact nature. Wiener,[2] in 1902, démonstrated that the administration of glycerin of various oxyacids, and especially of dibasic acids (of the aliphatic series) containing three carbon atoms, along with urea, increases markedly the formation of uric acid. Laboratory experiments had shown that urea can unite with dibasic acids containing three carbon atoms to form compounds called ureids, and that certain of these ureids can combine with another molecule of urea to form uric acid. While the feeding of any dibasic acid containing three carbon atoms to birds increases the uric-acid formation, Wiener found that when he used isolated organs only one dibasic acid, namely, tartronic acid (or its ureid) was effectual. He concluded, therefore, that other dibasic acids or their ureids are transformed into the ureid of tartronic acid in the process of uric-acid synthesis. Thus lactic acid (CH_3-CHOH-COOH), he thinks, is first transformed to tartronic acid (COOH-CHOH-COOH), and later unites with urea to form a ureid (dialuric acid), after which the addition of another urea molecule gives rise to uric acid. When the liver of the bird is removed, not only is the synthesis of uric acid itself prevented, but, in addition, the oxidation of lactic acid to tartronic acid is interfered with and ammonium lactate appears in the urine.

The principal mode of formation of uric acid in birds, then, is by the method of synthesis. Birds, however, do form some uric acid in the way in which it is chiefly formed in mammals, namely, through nuclein metabolism and through the transformation of the nucleins and xanthin bases of the food. We feel confident of this, because even after the removal of the liver in birds a little uric acid is excreted, and the feeding of hypoxanthin to birds deprived of their livers increases the amount of uric acid excreted (von Mach, 1888).

The question of a synthetic formation of uric acid in mammals and man now grew more interesting. If there are two modes of formation of the substance in birds, it would seem very probable that there are also two modes in mammals. On feeding lactic acid or dialuric acid (the ureid of tartronic acid) to human beings, Wiener, in 1902, found a slight but distinct increase in the uric-acid output. Now, since lactic acid is known to be one of the intermediary products of metabolism, he concluded that uric acid, under normal conditions, is synthesized, to a certain extent at least, even in man.

Another possible mode of formation of uric acid by the chemical union of simpler bodies is conceivable. It had been known since Strecker's work (1868) that uric acid can be broken up into glycocoll, carbon dioxid and ammonia. Maly suggested, as early as 1872, the possibility of a synthetic production of uric acid in the body from glycocoll, and ten years later Horbaczewski showed that, at any rate *in vitro*, glycocoll and urea can be synthesized to uric acid.

A beautiful experiment in physiologic chemistry, the synthesis by the kidney of benzoic acid and glycocoll with formation of hippuric acid, has for some time been known; it stimulated the imagination of investigators, and the relative excretion of hippuric acid and uric acid began to be watched. Weiss,[3] in 1898, asserted that after eating fruit the uric acid of the urine is decreased and the hippuric acid increased. He sought an explanation in the presence of China acid (tetraoxyhexahydrobenzoic acid) in the fruit, and assumed that the China acid in the body becoming changed into benzoic acid, unites with the available glycocoll to form hippuric acid, and so prevents the synthesis of uric acid from glycocoll. If this idea of Weiss were correct, then, as Wiener points out, all acids which can unite with glycocoll in the body should have the same effect, and benzoic acid itself should act even more definitely than China acid. On administration of benzoic acid, however, though the hippuric acid is increased, there is no decrease in uric-acid excretion (Weiss, Lewandowsky); moreover, salicylic acid, which pairs easily with glycocoll and, according to Weiss' theory, should diminish uric-acid excretion, is held by a whole series of observers to be one of the few drugs which increases it. It has also been shown that hippuric-acid formation goes on entirely independently of uric-acid formation (Weintraud, 1900), so that the doctrine of a competition for the available glycocoll can scarcely longer be held.

---

[1] Minkowski, O.: Ueber den Einfluss der Leberextirpation auf den Stoffwechsel, Arch. f. exper. Path. u. Pharmakol., Leipz., vol. xxi, 1886, pp. 41-87.

[2] Wiener, H.: Ueber synthetische Bildung der Harnsäure im Thierkörper, Beitr. z. chem. Physiol. u. Path., vol. ii, 1902, p. 42.

[3] Weiss, J.: Beiträge zur Erforschung der Bedingungen der Harnsäurebildung, Ztschr. f. physiol. chem., vol. xxv, 1898, p. 393.

The question of the synthesis of uric acid from glycocoll in the body, for the present, must be left open. That uric acid is formed, however, to a certain extent synthetically in man and mammals, we think, must be regarded as proved, even though the details of the combining processes are not yet fully understood. Minkowski's and Wiener's ideas have much in their favor, and we should not be surprised if the proof were ultimately brought that the synthesis of uric acid in the liver results from the union of tartronic acid, successively, with two molecules of urea. We are irresistibly led to the conclusion, therefore. that uric acid in the vertebrate animal body is formed both by an analytic and a synthetic process, the former predominating in man and mammals, the latter in birds and reptiles.

THE SMALL DEATH RATE FROM DISEASE IN THE JAPANESE ARMY.

If the facts reported in the newspapers are correct, the present war in Manchuria, especially as regards the Japanese losses, stands alone among the conflicts of modern times. It is said, on the authority of the chief surgeon of General Oku's army, that, out of presumably 100,000 combatants, only 40 died of disease during the seven months' active campaigning ending December 1. Out of 24,642 cases of disease treated, 18,578 recovered in field hospitals or while on duty; 5,609 were sent home for treatment, leaving only a little over 300 still on the army sick list at date of report. Allowing for considerable mortality among the cases sent to base hospitals in Japan these figures are almost if not absolutely record breaking. The fact is still more remarkable when we notice the record of typhoid fever and dysentery, ordinarily two of the most serious disorders of armies in the field. The Japanese figures are given as only 193 cases of the former and 342 of the latter. The medical department of the Japanese army must certainly have the secret of army sanitation. How much is due to racial peculiarities of the Japanese. whom we know to be a specially hardy and reasonably temperate people, is also an interesting question, but one that can not be satisfactorily answered. Of course, due allowance must be made for the fact that the figures on which we comment are by no means official, but it is quite evident that Japan has not had to contend with any very serious illness in the army in the field.

EFFECTIVE LOCAL ORGANIZATION.

Cleveland offered some of the earliest examples of progressive methods in medical organization, and proof of development in this line has been offered in a little brochure, just issued, entitled "The Academy of Medicine of Cleveland—Reports of Officers and Committees—1904." This pamphlet is an inspiration to hearty co-operative work, and should be read especially by those connected with similar societies. The reports can not adequately be summarized, but a few points may be noted to show the range of the work done. A special committee interviewed the newspaper editors regarding the protection of the members of the society from objectionable publicity. The regulation of ambulance service was considered, unethical medical institutions were investigated by a committee, and a city ordinance was secured that reduced the casualties of the Fourth of July celebration. The project for the academy and library to own a permanent home that would conveniently house all the medical activities also was considered. Remarkably good results were attained by a systematic canvass for new members, and the financial report is excellent. The report of the legislative committee is peculiarly interesting and instructive. The work of the committee on public health continues to be a model of efficiency. It holds regular weekly meetings, to which the president of the board of health and the health officer have a standing invitation. Thus the society has kept in close touch with the civic health, and it has exerted great influence in this direction on the city officials and citizens generally. The work of the academy, as a whole, has been crowned with success, and this success should stimulate like efforts in other towns and cities.

ERRORS IN OBSERVATION.

The physician is thoroughly conversant with the fact that observation is apt to be erroneous, and that the patient's story must often be liberally interpreted in accordance with other facts observed. Some interesting experiments are reported in the Berlin *Blätter für Volksgesundheitspflege.* Dr. L. W. Stern of Breslau examined twenty-four pupils concerning the details of an assembly room in which the class had met eight days before. The questions concerned the number of windows and doors, whether or not the windows were barred, etc. The results showed that every fifth statement was positively false; but that statements under oath were slightly more accurate. For example, the percentage of error was from 18 to 27 per cent. in ordinary statements, and from 8 to 10 per cent. under oath. In another experiment, a man entered the room, spoke to the instructor, handed him a manuscript, asked permission to consult a case of books in the room; took from this case a book which he read for five minutes, left the room with the book in his possession, etc. Eight days later, the spectators were asked to describe the whole proceeding. The positive statements were one-fourth false; statements as to what was said, one-third false. Dr. Stern says that the reports together formed "such a chaos of contradictory statements that if a judge had merely these statements to form an opinion by he could not possibly reach any conclusion." These experiments are interesting. We have before referred to a similar experiment in which a quarrel took place in a clinical amphitheater, and the students were examined concerning the details some days afterward. These results lend emphasis to the necessity for careful consideration of all facts in diagnosis, and the danger of placing too great dependence on any one statement by the patient which may be the crucial point of any decision.

THE DEPENDENT EPILEPTIC

While it is gratifying to note the increased interest shown in late years in the public care of epileptics, the care of these patients still lacks much of being what it should be. To Ohio belongs the credit of taking the lead in this matter, when she established, in 1890, the Ohio Hospital for Epileptics at Gallipolis, where 1,000 patients are now being cared for. According to recent reports, the capacity of the Ohio Hospital should be increased, for on Feb. 1, 1905, there were 250 patients awaiting admission, while the total epileptic population of the state, most of whom will probably become public charges sooner or later, is estimated at 2,750. New York State followed next in order, by founding, in 1894, the Craig Colony at Sonyea in Livingston County, which is still the only institution in the United States strictly along colony lines. At the Sonyea institution there are 1,006 patients, and nearly as many more are on the waiting list. The estimated epileptic population in New York State is 14,000. Sonyea is about to make provision for 250 additional patients, and it expects ultimately to care for 1,800 or 2,000 on its extensive area of 1,895 acres. Almost coincidently with New York, Massachusetts took up the question, and the Hospital for Epileptics at Palmer reflects the practical interest shown in that state. The number of patients at Palmer has reached 500, and there are 200 awaiting admission. The estimated epileptic population of Massachusetts is 10,000. The New Jersey Village for Epileptics at Skillman, near Princeton, was the fourth state institution to be founded. It now has 150 patients with 450 on the waiting list. The estimated number of epileptics in New Jersey is computed at not less than 2,500. Texas and Kansas are the most recent recruits among the states in this work. On a tract of 640 acres at Abilene, Texas, there has recently been established an epileptic colony that now has 220 patients, with a waiting list of 300, while it is estimated that there are 1,000 other dependent epileptics in the "Lone Star State." The State Hospital for Epileptics at Parsons, Kans., was opened a short time ago. It already has 200 patients, and, like the other institutions mentioned, it has a large waiting list. Indiana is now in line, for the higher branch of its legislature has appropriated $150,000 with which to begin the building of a colony for epileptics in that state. The Indiana bill provides a tract of not less than 1,000 acres of land at the outset. Most public institutions of this kind start with too small an acreage, and it is gratifying to learn that Indiana intends to avoid this particular mistake.

THE EARLY PUBLICATION OF THE RESULTS OF ORIGINAL RESEARCH.

Of all the various kinds of articles published in medical journals, the most important, all things considered, is the article embodying results of real investigative work, whatever the field occupied may be, in which a real effort has been made to enlarge the bounds of knowledge concerning the problems studied. This is the kind of article that the great American medical public as yet appreciates the least, and we fear that sometimes even medical editors are a little slow in grasping its value. In this country, in particular, medicine needs work of this kind, because we have been so much occupied with organization and with the necessary teaching of old knowledge that there has not been energy and opportunity enough to furnish what would seem to be a creditable share of new knowledge. Consequently, we have become good compilers and facile writers, which at times may be detrimental to critical penetration. It may be taken for granted that no well-educated physician will ever doubt the ultimate practical value of "the knowledge that ripens on the tree of medical science." It takes so long before the new fact, the new point of view, become part and parcel of general medical knowledge that no time should be lost in starting the new fact, or the new idea, on its career of increasing the usefulness of the medical profession. In many quarters doubt, uncertainty and opposition may be aroused by the publication of new work, and this may result in quickening of the investigative activities in many laboratories and clinics. Almost without exception, good new work is sure to prove of direct benefit to other workers in the same and in related fields. A large share of excellent, often epoch-making, investigative work in medicine has been done, and no doubt will continue to be done by comparatively young investigators. To many of them, the satisfaction incident to publicity may be the sole, immediate reward for many hours of patient toil in some obscure corner. Consequently, there is no good reason for unnecessary delay in the publication of the results of investigative work carried to a proper and natural finish. Everything speaks in favor of prompt publication, and in the case of general medical journals, articles of this kind, especially when it concerns problems in preventive and practical medicine, should have the right of way over those that do not present original work at first hand.

Medical News.

DELAWARE.

Voodoo Doctor Sentenced.—Daniel Hector, a colored voodoo doctor, pleaded guilty of witchcraft and fortune telling. He was sentenced, February 10, to be imprisoned for nine months and to stand in the pillory for one hour.

Personal.—Dr. Charles P. White, Wilmington, has been appointed assistant medical examiner for the Pennsylvania system at Pittsburg.——Dr. Samuel G. Elberts was thrown from his carriage, February 7, and broke his arm.——Dr. Joseph M. Martin, Lewes, was operated on for appendicitis, January 28.——Dr. John C. Fahey, former mayor of Wilmington, was operated on for abscess of the throat, February 3.

ILLINOIS.

Measles is reported to be epidemic at Curran.

Epidemic Disease at Lacon.—For the second time within three months, Lacon is suffering from an epidemic of scarlet fever, and now diphtheria also has appeared. The public schools have been ordered closed.

Board Increases Scope.—The scope of the work of the laboratory of the State Board of Health is to be so increased that it will become of greater benefit to the physicians of the state. With this end in view, container stations will be established in every county of the state where containers for bacteriologic specimens and blank forms for transmission may be secured in the shortest possible time. It is probable that these containers will be placed in the hands of the secretaries of county medical societies for distribution.

Chicago.

President Harper Ill.—President William R. Harper of the University of Chicago, who was operated on for appendicitis in March last, and who has been ill since September, is suffering from a tumor of the cecum. Dr. Harper's condition is causing his medical advisers great concern, and it is possible that operative interference may be necessary.

Smallpox is Marching On.—During the week 27 cases of smallpox were sent to the Isolation Hospital. Four had old scars said to be from vaccinations made in childhood, but had never been revaccinated; 23 never had been vaccinated at all; 7 were unvaccinated children under the school age of 6 years. Twelve of the patients came from the downtown lodging-houses.

Deaths of the Week.—During the week ended February 11 there were 554 deaths reported, equivalent to an annual mortality of 14.50 per 1,000. The rate for the previous week was 13.88, and for the corresponding week of 1904, 17.88. Pneumonia, as usual, leads, with 118 deaths; then follow consumption, with 68; bronchitis with 40; heart disease [illegible]7; Bright's disease with 32, and violence with 30. Smallp [illegible]

are two librarians and the collection is open to readers from 9 a. m. to 5 p. m. daily. The library is a circulating one, and all the privileges of it can be secured by any physician by the payment of $2 a year. The collection has had a continuous existence since 1813, and is, therefore, one of the oldest medical libraries in America. It is also one of the best and best conducted, having a very complete card catalogue. Recent additions have been the library of the late Dr. A. H. Powell, and a large part of that of the late Dr. Julian J. Chisolm. At present it occupies a suite of rooms in the main university building, but it will be moved in the spring to larger and better quarters. The collection is especially rich in rare works of the sixteenth and seventeenth centuries, the original nucleus purchased on the death of Dr. John Crawford.

MASSACHUSETTS.

Hospital Improvements at Waltham.—Several improvements are to be made in the Waltham Hospital. About $75,000 will be expended in remodeling the interior of the administration building and the addition of an engineer's room.

Died Outside Hospital Gate.—Newspapers have been criticizing the management of the Massachusetts General Hospital because of the refusal of the office attendant to do anything for a man who had fallen unconscious just outside their gate When the police were summoned and he was carried in by them he was found to be dead.

Health Appropriations.—Mayor Collins of Boston recommends the following appropriations: Bath Department, $160,000; Health Department, $200,000; Hospital Department, $485,000; Children's Institution Department, $188,000; Insane Hospital De[illegible]ent, $169,000; Pauper Institutions Department, $20[illegible] Water Department, $904,309. This is an increa[illegible]0 to [illegible] Bath Department and of $4,000 to the [illegible]rtm[illegible]le the Hospital Department remains [illegible] and [illegible] a net decrease in the Insane Hosp[illegible]000, owing to the assumption of the [illegible]e of this [illegible]s of patients.

before this body, and have dwarfed every other issue now before the legislature. The whole subject of water supply, as it affects New York City, will be thrashed out before the several committees or joint hearings next week.——A bill has been introduced to regulate the practice of osteopathy along the lines prescribed for regular medicine. It provides for the appointment by the regents of a board of five examiners from a list to be submitted each year by the New York Osteopathic Society. It specifies in what subjects candidates shall be examined, and provides that such candidates must be graduates of a twenty-seven months' course at a regular school of osteopathy. The maximum penalty for practicing osteopathy without a license is fixed at $250 fine or six months' imprisonment for the first offense, and twice that amount for subsequent offenses. A similar bill was defeated two years ago in committee.——The Senate Cities Committee has reported favorably on the Elsberg bill abolishing the coroners in New York City. The bill will probably pass the senate next week. ——A bill has been introduced in the legislature which abolishes the boards of visitation and creates local boards of seven members each, to be appointed by the governor and removed by him, to serve without compensation. Control of expenditures and the general supervision are still to rest in the State Commission in Lunacy.

Buffalo.

Measles in Asylum.—There are 62 cases of measles at the Buffalo Orphan Asylum.

Appointments.—Mayor Knight has appointed Drs. Lawrence G. Hanley and George H. McMichael civil service commissioners.

Cigar Makers Have Phthisis.—It is stated that 50 per cent. of all workers in cigar factories in Buffalo ultimately die of consumption.

Consumptive Domiciles.—A list of all houses showing more than one death from consumption has been submitted to the health department by the charity organization committee on tenements, there being 146 houses of the kind. Much work has been done in fumigating such places. The committee has a card index of all such cases.

Milk Inspection.—According to investigations made by Health Commissioner Greene there are about 800 milk dealers outside of the city who send their milk to Buffalo. The aggregate amount of milk thus obtained is 9,000.000 gallons per year. He desires the ordinance changed so that five additional milk inspectors and one assistant bacteriologist may be appointed for Buffalo.

New York City.

New Health Officer for Brooklyn.—Dr. Thomas L. Fogarty has been appointed assistant sanitary superintendent for the Borough of Brooklyn.

Cerebrospinal Meningitis.—This disease has gained such prevalence during the past month among the children that physicians fear a return of the epidemic of a year ago.

City Raises Salaries.— The salaries of many employes in city departments have been materially increased. The health department has received $15,494 for this purpose; Bellevue and the allied hospitals $6,868, and the department of charities $11,000.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended February 4, 343 cases of tuberculosis, with 180 deaths; 311 cases of diphtheria, with 49 deaths; 233 cases of scarlet fever, with 15 deaths; 185 cases of measles, with 8 deaths; 135 cases of chickenpox; 32 cases of typhoid fever, with 10 deaths; 1 case of smallpox, with 1 death; and 33 deaths from cerebrospinal meningitis. This is a total of 1.240 cases and 296 deaths.

War Against Spitters.—The health department has begun work against the spitters in earnest. Twenty-five sanitary squad policemen have been detailed to look after this class of offenders during the evenings in the streets of the city. A large number of arrests were made during the first evening, among them two in the lobby of the Metropolitan Opera House. Hitherto offenders have been warned and only arrested when they failed to obey, but henceforth no warning will be given.

Food Adulteration.—At a meeting of the New York Health Protective Association, February 8, Dr. R. E. Doolittle of the United States Department of Agriculture showed samples of various adulterated articles of food. He said that most of the jellies sold by grocers came from the refuse of dried apple factories and consisted of starch paste, sweetened with glucose, colored with coal-tar dyes, flavored with chemicals and preserved with salicylic acid. Coffee was adulterated with chicory, pea hulls and wheat middlings, many flavorings are about 90 per cent. wood alcohol, cream of tartar is plaster and phosphate of lime, etc. The members of the association thought that as we were protected against adulterated imported articles, it would be better to use imported products of this class, and thus bring our home manufacturers to see that it would be to their advantage to furnish a pure article. The influence of the Health Protective Association was sought for the purpose of urging the passage of the food bill now before congress.

OHIO.

Hospital Notes.—Elyria Hospital was formally opened January 23, with a public reception. The institution has accommodation for twenty patients.——Columbus Children's Hospital will receive more than a quarter of a million dollars by the will of the late William W. Franklin.

Library Association Meeting.—At the second annual meeting of the Cincinnati Medical Library Association, Dr. Henry W. Bettmann was elected president; Dr. Joseph Eichberg, vice-president; Dr. Alfred Friedlander, secretary; Dr. William H. Crane, treasurer, and Dr. Arch I. Carson, librarian.

State Board Will Aid in Diagnosis.—To aid physicians in making a diagnosis in suspected or doubtful cases of certain of the infectious diseases, and thereby to enable the health authorities better to control them, the State Board of Health offers to make examinations free of charge, on the request of any physician, of specimens from suspected cases of pulmonary tuberculosis, diphtheria or typhoid fever.

Academy Election.—At the annual meeting of the Academy of Medicine of Toledo and Lucas County, January 18, the following officers were elected: Dr. Thomas Hubbard, president; Dr. William G. Dice, vice-president; Dr. Louis A. Levison, secretary; Dr. John G. Keller, treasurer; Dr. James A. Duncan, financial secretary, and Drs. William J. Gillette, Oscar Hasencamp, Herbert E. Smead and William H. Fisher, censors, all of Toledo.

Personal.—Dr. Joel B. Taylor has been appointed a member of the Marion Board of Health, vice Dr. Elmer O. Richardson, resigned.——Dr. William C. Heintz, Columbus, is ill with typhoid fever at Grant Hospital in that city.——Dr. John C. Reeve, Dayton, was the guest of honor at a banquet, February 9.——Dr. Kent B. Waite, Cleveland, has been adjudged insane and committed to the State Hospital for the Insane.——Dr. Robert C. Chamberlain, Tiffin, has been elected physician to the Seneca County Infirmary.——Dr. Harry E. Welch, Youngstown, has been made local surgeon for the Erie Railway, between Girard and Hubbard.——Dr. George C. Altmeier, Cincinnati, has been appointed district physician of the twenty-second ward, vice Dr. Augustus J. Hofling, deceased.——Dr. Edward S. Johnston, Cincinnati, who was recently operated on for appendicitis, is making satisfactory progress toward recovery.

PENNSYLVANIA.

Personal.—Dr. J. C. Biddle, superintendent of the State Miners' Hospital at Ashland, was thrown from his sleigh on January 30, and severely injured.

Norristown's Vital Statistics.—The annual report of the bureau of vital statistics shows that there were 402 deaths last year, an increase of 68 over the preceding year, and 350 births, an increase of 50 over 1903.

Smallpox at Portage.—Smallpox threatens to become epidemic at Portage, Cambria County. Several new cases have been reported, and it is asserted that more than a score of patients are afflicted. The State Board of Health has ordered the town authorities to provide an isolation hospital, and unless this order is complied with, the town may be quarantined.

Chicken-pox at Gettysburg.—The cases of supposed smallpox reported in Gettysburg College have been pronounced by Dr. William M. Welch, of the Municipal Hospital, Philadelphia, to be typical cases of chicken-pox. Dr. Welch made the investigation for the board of health at the request of the college faculty. The cases were first reported in the lay press to be smallpox.

Philadelphia.

Personal.—Dr. Frank C. Parker was elected assistant surgeon at the Wills Eye Hospital, vice Dr. Archibald G. Thomson, resigned.

Lectures on Care of Teeth.—On Fridays in March the public school children and their parents are to be enlightened on the care of the teeth by a series of talks, to be given in the school buildings throughout the city by Dr. J. Ashley Faught.

Spring Will Soon Be Here.—As a result of the persistent complaints of the patrons of the city trolley cars as to their unheated and insanitary condition, the president of the traction company has promised that in a short time all cars of the city shall be properly heated.

Bequests.—By the will of Mary C. Dulles, a contingent bequest of $10,000 is made for the maintenance of the Margaret Welch Dulles Memorial ward in the Presbyterian Hospital. The will also bequeathes $2,000 for improvements to the Presbyterian Hospital; the Childrens' Seashore Home receives $1,000, and Day Nursery $1,000, and the Presbyterian Orphanage, $2,500.

Explosion at Samaritan Hospital.—An explosion of ether occurred in the operating room in the Samaritan Hospital, February 10, during a tracheotomy. Oxygen used in the operation blew the ether into the gas flame, resulting in its explosion. Dr. H. C. Cunningham, the resident physician and anesthetizer, and Dr. H. A. Duncan were rather severely burned. Two medical students were also slightly burned. The patient was uninjured.

Hospital Reports.—Report of the hospitals for January are as follows: The Polyclinic Hospital admitted 124 patients to the wards, and treated 1,280 new cases in the dispensary; a total of 6,103 patients were treated in the different dispensaries, and 593 accident cases were received.——The Medico-Chirurgical Hospital treated a total of 5,438 patients.——One hundred and eighty-three patients were admitted to the wards of St. Agnes Hospital, and the total number treated in the different dispensaries aggregated 2,366.

Health Report.—The total number of deaths from all causes for the week ended February 4 aggregated 538. This is an increase of 39 over those of last week and a decrease of 85 as compared with those of the corresponding period of last year. About one-third of the deaths resulted from lung affections. Of these, 100 deaths resulted from pneumonia and 56 from pulmonary tuberculosis. There were 22 deaths from cancer, 25 from apoplexy, 61 from heart disease, 47 from Bright's disease, 20 from enteritis, and 7 from typhoid fever. There were 188 cases of contagious disease reported, with 20 deaths, as compared with 207 cases and 23 deaths for the preceding 7 days. The total number of deaths reported for last week was 612. This is an increase of 74 over those of last week, and an increase of 44 over the corresponding period of last year. One hundred and seventeen deaths resulted from pneumonia alone, which is an increase of 35 over those of last week. The deaths from tuberculosis were also unusually high, numbering 67. Influenza caused 13 deaths. Several other deaths resulted from acute inflammation of the respiratory tract, which also should probably be classified with the deaths resulting from pneumonia; 15 of these were reported as congestion of the lung, and 19 from acute bronchitis. The deaths from disease of the respiratory tract aggregate more than one-fourth of the entire number of deaths from all causes. The principal causes of death were as follows: typhoid fever, 8; diphtheria, 11; influenza, 13: tuberculosis, 67: cancer, 13: apoplexy, 26; heart disease, 71; inflammation of respiratory tract, 152; Bright's disease, 50; senility, 24. The contagious disease cases reported number 199, with 23 deaths, as compared with 208 cases and 20 deaths for the preceding week. There were 19 cases of typhoid fever reported.

Jewish Hospital Staff.—The following physicians have been appointed for the ensuing year to the staff of the Jewish Hospital by the president, William B. Hackenburg: Consulting surgeons—Drs. William W. Keen, J. William White, John B. Roberts, Edward E. Montgomery, Orville Horwitz, John M. Baldy, and Charles P. Noble. Surgeons—Drs. Benjamin B. Wilson, Lewis W. Steinbach, William H. Teller, William L. Rodman, Max J. Stern, and Melvin M. Franklin. Orthopedic surgeon—Dr. DeForest Willard. Ophthalmologists—Drs. Isaac Leopold and Jay C. Knipe. Neurologists—Drs. Francis X. Dercum and Max H. Bochroch. Otologists—Drs. S. MacCuen Smith and Eli L. Klopp. Laryngologists—Drs. Arthur W. Watson and Louis Jurist. Obstetrician—Dr. William H. Randle. Pediatrists—Drs. Thompson S. Wescott, Ludwig Loeb and Joseph B. Potsdamer. Pathologist—Dr. Courtland Y. White. Dermatologist—Dr. Jay F. Schamberg. Radiologist—Dr. Sydney L. Feldstein. Consulting physicians—Drs. John H. Musser, James Tyson, James C. Wilson, Roland G. Curtin, Alfred Stengel, James M. Anders, and Lawrence F. Flick. Consulting pediatrist—Dr. J. P. Crozer Griffith. Physicians—Drs. Adolph Feldstein, Thomas Betts, Solomon Solis-Cohen, William A. Cross, Francis X. Dercum, David Riesman and Courtland Y. White. Assistant physicians—Drs. Moses H. Behrend, Bernard Kohn, William A. Rocap, Edwin I. Becker, Victor A. Loeb, Maurice J. Karpeles, Harry F. Webster, Myer Solis-Cohen, George P. Katzenstein, Louis H. Jacobs, Milton K. Myers, William Shields, George W. Cook, Samuel Leopold, Mortimer Herzberg and Robert F. Ridpath. Chief resident physician—Dr. Edwin A. Jarecki.

Bills Before the Legislature.—A bill suggested by Coroner Dugan, as a result of several recent sensational murder trials, will be introduced into the legislature asking the prohibition of the use of embalming fluids containing arsenic, mercury or carbolic acid, and asking that these agents shall not be used in the preservation of dead bodies and shall not be used in embalming fluids. Among other bills introduced is one making vaccination compulsory on all persons who have not been successfully vaccinated within 5 years, and providing for arrest and fine for violation of the law. Another health bill requires the examination and licensing of midwives. A bill relating to vital statistics has been presented, making failure of midwives or physicians to report births, clergymen or magistrates to report marriages, or physicians to report deaths a misdemeanor. The most important bill introduced is one giving absolute power to the boards of health of all cities, counties, townships and boroughs, in dealing with cases of contagious disease. There are included in the list of contagious disease, beside smallpox, diphtheria and scarlet fever, such maladies as chicken-pox, measles, mumps, whooping cough, influenza and pneumonia. In all cases the boards are to have power to make rules and regulations governing reports to be made by persons attending the sick, the quarantining and disinfecting of persons and premises, the placarding of notices, and the placing of guards to enforce the same; the total destruction of infected bedding, clothing or other articles; the care and burial of persons who may have died from these diseases; fixing the limit of time for burial; methods to be used in advertising the funeral; the disinfection of all conveyances used in the burial; the attendance of persons at public and private schools, and the compulsory vaccination of all persons employed therein.

Tuberculosis Decreasing.—According to the statement made in the first annual report of the Henry Phipps Institute, tuberculosis is on the decrease in this city. This statement is based on the results of investigation of the official records from 1861 to 1903, inclusive. The report shows a rapid decrease from 1887 to 1897, inclusive, a slight decrease prior to 1887 and a slight increase after 1897. In 1870 the mortality from the disease was the highest, the death rate being 3.78 for 1,000. The report attributes this to the influence of the Civil War, which had just closed. From 1871 to 1874 there was a steady decline, but from 1874 to 1876 there was an increase of 0.37 per 1,000. This may have been accounted for, they claim, by the large number of persons visiting the city during the exposition and by the epidemic of smallpox in 1872. The apparent decrease from 1876 to 1880 is not a true one. It was estimated on the figures published by the board of health, which were disproved by the census of 1880. The mortality in 1880 was 3.27 per 1,000. From that time to 1902 there has been a continual decrease, but in 1903 there was an increase of 0.12 per 1,000. This slight increase may be due in part to a great increase in emigration from Russia and Poland, it having been double that of the ten previous years. The principal cause, however, they believe, is the accuracy in diagnosis through the bacteriologic department of the board of health. The report further shows that in 1903, 2,030 patients were received and treated in the Henry Phipps Institute; of these 1,130 were native born, 769 were foreign born, and 140 had no nativity record. Many of the foreign-born had been in this country so short a time that it was assumed they had the disease when they landed here. The number of negroes admitted was about 6½ per cent. of the whole number, but the proportion of negro admissions to white admissions was greater than is the proportion of the negro to the white population of the city. The longest stay of any patient in the hospital was 286 days, and although this was an advanced case the patient improved steadily. The results of treatment show that 537 cases were reported improved, 583 unimproved, 881 not recorded, and 153 died. The report also contains a paper on "The History of the Tuberculosis Work at Saranac Lake," by

Dr. Edward L. Trudeau; one on the "Home and Its Relation to the Tuberculosis Problem," by Dr. William Osler; "Pulmonary Tuberculosis," by Dr. G. Sims Woodhead of London, Eng.; "The Administrative Control of Tuberculosis," by Dr. Herman M. Biggs, and "Specific Therapy of Tuberculosis," and "Vaccination Against the Disease," by Dr. Edward Maragliano of Italy. The first report is very complete, and shows that the work of the year has been most thorough.

RHODE ISLAND.

Accidental Asphyxiation.—Dr. Elmer B. Eddy, Olneyville, Providence, was found unconscious in his office, January 30, from gas asphyxiation. After an hour's work Dr. Austin H. Longfellow pronounced Dr. Eddy out of danger.

Election at Newport.—The Newport Medical Society, at its annual meeting, elected the following officers: Dr. Christopher F. Barker, president; Dr. V. Mott Francis, vice-president; Dr. Mary E. Baldwin, secretary; Dr. Douglas P. A. Jacoby, treasurer; Dr. Harry J. Knapp, curator; Dr. William A. Sherman, bacteriologist; Drs. V. Mott Francis, William S. Sherman, and Samuel P. Cottrell, executive committee, and Drs. William S. Sherman, Douglas P. A. Jacoby, and Stephen C. Powell, censors.

TENNESSEE.

Hospital To Be Built.—A permit has been issued for the building of a hospital for the Tennessee Medical College, Knoxville, to cost $30,000.

Personal.—Dr. J. Sinclair Dye has been appointed to succeed himself as city physician of Chattanooga.——F. Emmett Downey, a member of the senior class of the medical department of Grant University, Chattanooga, died recently at the Erlanger Hospital in that city, after an illness of two weeks, aged 22.

Trouble at Knoxville General Hospital.—In consideration of the open antagonism of W. P. Chamberlain, chairman of the board of governors of the Knoxville General Hospital, Drs. Charles P. McNabb, Samuel M. Miller, Benjamin B. Cates, Ernest R. Zemp, Walter S. Nash, Samuel L. Jones, Benjamin F. Young, and A. G. Kern have resigned from the staff of the institution.

Hospital Staff Enlarged.—The staff of Erlanger Hospital, Chattanooga, has been increased by ten, five of whom, Drs. William T. Hope, William A. Applegate, Frank T. Smith, Philander D. Sims and L. Y. Green are selected from the faculty of the medical department of the Grant University, and will serve from October, 1905, to April, 1906. The other five, selected from the Chattanooga and Hamilton County Medical Society, will go on duty April 1, 1905, and serve until October 1. They are Drs. Clarence A. Cobleigh, Abraham W. Boyd, Thomas E. Abernathy, Edward B. Wise and Young L. Abernathy.

Society News.—Humphreys County Medical Association, at its annual meeting, elected Dr. James J. Teas, Bakerville, president; Dr. W. R. Horner, Clydeton, vice-president, and Dr. Claude C. Sullivan, Waverly, secretary and treasurer.——At its annual meeting, the Rutherford County Medical Society elected Dr. Enoch H. Jones, Murfreesboro, president; Dr. Edgar C. Freas, Lascassas, vice-president; Dr. Rufus Pitts, Murfreesboro, secretary; Dr. Vernon K. Earthman, treasurer; Dr. Edgar C. Freas, Lascassas, delegate to the Tennessee State Medical Association; Dr. Harry C. Reese, Murfreesboro, alternate, and Dr. James B. Murfree, Sr., Murfreesboro, censor.

TEXAS.

La Grippe is said to be epidemic at Denton, where 1,200 cases are reported, and at Taylor, where, it is said, there are 700 cases.

Sanitarium Opened.—Providence Sanitarium, Waco, built and equipped by the Sisters of St. Vincent de Paul at Dallas, at a cost of $150,000, was formally opened January 11.

Smallpox.—At Eddy the disease is prevalent and a strict quarantine is maintained.——Miles has had about 50 cases, without a death.——The city health officer of Rockdale, on January 29, in a house-to-house visitation, vaccinated 200 negroes. The disease is confined to the negro population.——Mail delivery at Hartzo has been stopped by the postoffice department on account of the prevalence of the disease, which made its appearance at the postoffice building.

Quarantine Officers Named.—On the recommendation of Dr. George R. Tabor, state health officer, the governor has appointed the following state quarantine officers: Dr. Edgar F. McClendon of Bastrop County, at Galveston; Bartlett N. Sims of Kendall County, at El Paso; P. J. Shaver of Hunt County, at Sabine; John M. McKnight of Webb County, at Laredo; Isaac H. Brewton of Val Verde County, at Eagle Pass; J. H. Florence of Dallas County, at Brownsville; T. J. McFarland of Lavaca County, at Pass Cavallo; John F. Eaves of Brazos County, at Aransas Pass, and Benjamin H. Carleton of Brazoria County, at Velasco.

Personal.—Dr. John S. Turner, Ferrell, has been re-elected superintendent; Dr. James R. Nichols, Terrell, first assistant physician, and Dr. George F. Powell, Terrell, second assistant: Dr. W. M. Fullbright, Mount Vernon, has been elected third assistant, vice Dr. Scott Appleby, resigned, and Dr. C. M. Poff, Ellis County, fourth assistant, vice Dr. A. LaP. Thomas, resigned, all of the North Texas Hospital for the Insane, Terrell.——Dr. A. B. Gardner, Denison, was thrown out of his buggy, in a runaway, January 5, and fractured his clavicle.——Dr. Thomas J. Bennett, Austin, to avoid running over a boy, January 29, turned his automobile so suddenly that it overturned, wrecking the machine and severely bruising Dr. Bennett.

VERMONT.

Personal.—Dr. Summer E. Darling, Hardwick, has been elected a member of the state tuberculosis commission, vice Dr. Lorenzo W. Hubbard, Lyndon, resigned.

New State Board.—The State Board of Medical Registration created by act of the legislature last year, and consisting of Drs. W. Scott, Nay, Underhill and F. H. Godfrey, Chelsea, each for six years; Drs. Elroy B. Whitaker, Barre, and J. Sutcliffe Hill, Bellows Falls, each for four years, and Drs. Sam Sparhawk, Burlington, Henry Janes, Waterbury, and A. E. Parlin, Barton's Landing, each for two years, met January 10 and organized, electing Dr. Janes chairman, Dr. Nay secretary, and Dr. Whitaker treasurer.

Care of Eyes and Ears of School Children.—A bill has been passed by the legislature, to take effect July 1, providing for the better care of the health of pupils in public schools, which provides:

> The State Board of Health and the Superintendent of Education shall prepare suitable test cards, blanks, record books, etc., to be used in testing the sight and hearing of pupils in public schools and necessary instructions for their use; and the Superintendent of Education shall furnish the same, free of expense, to every school in the state. The superintendent, principal or teacher in every school, during September in each year, shall test the sight and hearing of all pupils under his charge and keep a record of such examinations according to the instructions furnished; and shall notify in writing the parent or guardian of every pupil who shall be found to have any defect of vision or hearing or disease of eyes or ears, with a brief statement of such defect or disease; and shall make a written report of all such examinations to the Superintendent of Education as he may require.
>
> The State Auditor is directed to draw his order on the State Treasurer for such sums and at such times as the Superintendent of Education, with the approval of the State Board of Health, may require to carry out the provisions of this act. The total expense under this act shall not exceed $600 in any biennial term.

GENERAL.

Annual Conference of the Gulf States Quarantine Boards.—The annual conference of the Gulf States Quarantine Boards, for the regulation of quarantine matters, will be held in Mobile early in March.

The Samuel D. Gross Prize, of the Philadelphia Academy of Surgery for 1905, amounting to $1,200, has been awarded to Dr. James Homer Wright, Boston, for his essay, "The Biology of the Micro-organism of Actinomycosis."

Sanitarium for Lepers.—Senator Crane of Massachusetts introduced a bill in the senate, appropriating $250,000 for the establishment of an institution for the segregation of lepers, and prevent the spread of leprosy in the United States. The bill provides that the institution shall be located on some abandoned military reservation or other suitable site owned by the United States. The house committee on interstate commerce also considered two bills regarding the care of lepers. One provides for the establishment of a sanitarium in this country, to which may be sent all lepers in the United States, and another appropriates $150,000, to be used in Hawaii for the scientific study of the disease.

Panama Health Conditions.—In a cablegram to the War Department Gov. Davis of Panama gives the following summary of Isthmus conditions: In the families of the Americans employed on the Isthmus, only three cases of yellow fever have occurred, and one death. Of the employes hired on the Isthmus five have had yellow fever and one has died. Among the Americans not employed on the Isthmus, including those of the cruiser Boston, there have been nine cases of yellow fever and five deaths. The total number of cases originating on the Isthmus is thirty-two, of which nine have proved fatal. Six cases are now convalescing. Since the American occupation, the dispatch says, two cases of smallpox have been reported, but none has originated there. There is no typhoid or plague. Of the 4,000 employes only 3 per cent. are ill of any disease. Governor Davis says that the sanitation of Panama is progressing as efficiently as in any city of the United States.

CANADA.

The "Canadian Nurse" is a new publication shortly to be issued from Toronto.

The Peterboro, Ontario, Sanitarium Association was formed, February 9, to erect a sanitarium.

Personal.—Dr. A. E. Douglas, Hunter River, Prince Edward Island, has been chosen speaker of the Prince Edward Island legislature.——Dr. J. M. Lefevre, Vancouver, B.C., has returned to Canada from England.

Closer Relations Wanted at McGill.—The faculty of medicine of McGill University, in the interests of medical education in Montreal, has asked for full union with the university. The board of governors welcomed the proposal, and will arrange for a special meeting to consider details.

Toronto's Health During January.—The following cases of contagious diseases were reported in Toronto during January, 1905, as compared with January, 1904: Diphtheria, 187, 1904, 146; scarlet fever, 48, 1904, 37; typhoid fever, 14, 1904, 2. The births, marriages and deaths during January were 412, 293 and 333 respectively. The deaths under five years were 109, over 70, 54.

The Lepers of Canada.—Dr. Smith, medical superintendent of the Leper Hospital at Tracadie, N. B., has made his annual report to the federal parliament. There are now fifteen residents in the institution, ten males and five females, the youngest patient being ten years and the oldest 62 years. The use of Chaulmoogra oil was introduced two years ago with some success. Dr. Smith, after careful investigation, is convinced that leprosy is communicable through contagion.

Searching a Maternity Hospital.—An unheard of proceeding took place recently in Montreal, when a deputy high constable and a special constable obtained admission to the Montreal Maternity Hospital, and in spite of assurances on the part of physicians and nurses that the individual they sought was not there, wantonly searched every bed in the institution, both private and public, but without locating the person sought. The legal adviser of the hospital has been instructed to take proceedings against these two men.

To Establish British Columbia Board of Health.—An important conference in Vancouver, February 3, will probably result in the establishment of a properly constituted board of health for the province, as suggested by Dr. Brydone-Jack of Vancouver, the members of which will be medical men. At present the arrangements provide a health officer who consults with the provincial cabinet. It is announced that a thorough revision of the health regulations of the province may take place at the present meeting of the legislature.

Canadian Physicians and the British Medical Act.—General Laurie, member of the British house of commons, and formerly a member of the Canadian house of commons, is the author of a bill, which seeks to amend the British Medical Act of 1858. This measure has been before the English house of commons both in 1903 and 1904, in the latter year being supported by two representatives of the general medical council, Sir Walter Foster and Sir John Tuke. This amendment to the medical act seeks to remove those disabilities under which colonially trained physicians and surgeons lie, in that they are not permitted to serve as such in either the British army or navy. The matter is before the local medical societies of Canada, and resolutions are being forwarded to Lieutenant-General Laurie, so that when he next brings the measure before the house of commons he will have evidence to prove that Canadians desire such disabilities removed.

Ontario Board of Health.—At the regular quarterly meeting of the Ontario Board of Health in Toronto recently, the chairman, Dr. E. E. Kitchen of St. George, presented his annual report. The past year has been a satisfactory one, so far as the health of the province was concerned. There was a great difference in the deaths from scarlet fever over those of 1903, when 529 died from that disease alone. In 1904, the deaths from scarlet fever numbered 129. The deaths from diphtheria remained about the same, viz., 438, while the deaths from typhoid fever ran from 298 in 1903 to 397 in 1904. The deaths from tuberculosis also show an increase from 2,072 in 1903 to 2,168 in 1904. Dr. Amyot, the bacteriologist of the board, in presenting his report, stated that during the past year a number of patent medicines had been subjected to examination, in which a large amount of alcohol had been found. The secretary reported the number of deaths for 1904 as 25,415, a rate of 12.8 per 1,000.

FOREIGN.

Medal for Ramon y Cajal.—The Prussian Academy of Sciences has presented the Helmholtz medal this year to Ramon y Cajal of Madrid.

New Hospital in City of Mexico.—President Diaz opened the new General Hospital in the City of Mexico February 5. The construction of the hospital was commenced several years ago, and has cost many thousand dollars. It consists of many pavilions, because many of the hospitals in the city will be merged in this new hospital.

Hospital Administration at Berlin.—The new Virchow hospital at Berlin is to have a similar administrative body as the three other city hospitals there. This body consists of the chief of the surgical department, the chief of the internal medicine department, and an administrative director. This triple head is found the best working organization for the management of these institutions.

Cancer Research in Baden.—A number of physicians and surgeons gathered, January 21, at Heidelberg to organize a cancer research committee. The minister of the interior for Baden was chairman of the meeting and Prof. V. Czerny of Heidelberg was appointed chairman of the committee. A collective inquiry is to be undertaken throughout Baden, and a number of special questions are to be investigated.

Patent Medicine Laws in Venezuela.—It is reported that the Venezuelan government has adopted regulations whereby all medicines not duly authorized and approved by the board of physicians shall be excluded from the republic. Large quantities of patent medicines have been annually exported from the United States and from other countries to Venezuela, and need of some action to protect the people has been imperative.

New Hospital in Pekin.—A hospital has just been completed by the Presbyterian Board of Foreign Missions in Pekin, to replace the one destroyed by the Boxers several years ago. The good feeling that the native merchants have for the hospital was made evident by the fact that they were present in large numbers at the dedication exercises, at which the United States Minister, Mr. Conger, made one of the addresses. There were also present a number of Chinese officials.

Reform in Exhibitions at Medical and Surgical Congresses.—The German manufacturers of surgical appliances held a conference at Berlin recently, in which resolutions were adopted urging that those in charge of exhibitions connected with medical and surgical congresses should be more discriminating in accepting exhibits. The committee passing on the exhibits should contain at least one technical expert, and the exhibitions should be held less often—once in three years was considered often enough.

Vital Statistics in Italy.—The *Riforma Medica* states that the number of deaths in Italy from scarlet fever has dropped from 14,000 in 1887 to 1,500 in 1900; from 28,000 to less than 6,000 deaths from diphtheria; from 24,000 to about 9,000 from measles; from 28,000 to 15,000 from typhoid fever, and from 16,000 to 316 from smallpox. On the other hand, the mortality from pulmonary tuberculosis has increased from 32,000 to 40,000, and that from pneumonia has risen from 63,701 in 1887 to 76,101 in 1900.

Tuberculosis Winter Day-Resort.—A winter day-sanatorium for the treatment of tuberculosis has been opened at Eichkamp, in the Grünwald, the great pine forest near Berlin. The *British Medical Journal* states that eight such institutions are open to the Berlin working classes during the summer, but this is the first that has been fitted up for the reception of patients in winter. In acknowledgment of the unwearying efforts in behalf of the sanatorium movement of Frau Studt, wife of the Prussian minister for home affairs, this institution is to bear the name "Luise Studt Erholungstätte."

Dispensary Abuses at Berlin.—The Prussian budget for this year contains an appropriation of about $52,400 solely to make up the deficit at von Bergmann's surgical policlinic from the past year. The fame of the operator attracts crowds to the clinic, many of them probably able to pay for surgical tendance. The authorities are taking steps to prevent this overcrowding of the clinic, which is far beyond what is needed for teaching purposes. They are devising means to sift out those able to pay for surgical work, and to make the clinic more self-supporting.

Information Bureau at Berlin.—An office has been opened on the ground floor of the university building at Berlin, near the main entrance, to serve as an information bureau for scientific educational matters. Students and others can obtain all possible information in regard to courses, lectures, prices, etc., and every possible information will be afforded for the prosecution of special scientific research by foreigners. Questions sent by mail will be answered. The office is to be open mornings and evenings, except during vacations, when the morning hours only will be retained. The official name of the bureau is the "Akademische Auskunftsstelle." The similar information bureau at Paris has fully established its usefulness during the year or so it has been in operation. It has been previously described in these columns.

School Inspector Dismissed.—Dr. Goldfeld has been medical inspector of the schools at Schöneberg near Berlin, and last July he read an article before the Woman's Temperance Union of the town on the use of liquor by the school children. His article was based on personal investigations, and it was published in several temperance journals, and extracts from it were given in some of the daily papers at home and abroad. The citizens association (Bürgerverein) became enraged at this publicity, bringing scandal on the town, and the city authorities were petitioned to discharge Dr. Goldfeld. In collecting his statistics he was said to have overstepped his line of duty as medical school inspector. The mayor (Stadtmagistrat) summarily dismissed Dr. Goldfeld. The city council passed a unanimous resolution asking that the physician be reinstated. The mayor has refused to do this. Physicians throughout Germany are watching with great interest the outcome of this serious disagreement between the municipal authorities over the medical school inspector.

Fund for Original Research in Australia.—Mr. David Syme of Melbourne, has given $15,000 to found a prize for the encouragement of original research. The *Australasian Medical Gazette* states that the council of the University of Melbourne has decided on the regulations for awarding the prize, which is to consist of $500 and a medal. It will be open to competition in March, 1906, and similarly in each succeeding year. Any person, resident in Australia for not less than five years, is eligible, except professors in Australian universities or heads of scientific departments under any Australian government. The prize is to be awarded to the candidate who, in the opinion of the examiners, submits the best thesis based on original work in one or other of the following branches of science: Biology, chemistry, geology or natural philosophy. Other things being equal, preference will be given to original research connected with the material and industrial development of Australia. If a thesis submitted as the joint work of two or more authors be awarded the prize, it will be equally divided between such authors.

The Berne Serum Institute and the Typhoid Epidemic.—A letter from Switzerland in the *Deutsche med. Wochft.* of January 12, relates particulars in regard to the last typhoid epidemic at Berne which had a tendency to discredit the medical profession in the eyes of the laity. The serum institute there, which is supported by the state, has been in the habit of sending to the slaughter-house the animals for which it had no further use. It happened and the public learned that the meat of a horse which had been inoculated with typhoid bacilli was sold in the market two or three days before the outbreak of the epidemic. Notwithstanding that the incubation period and other conditions did not harmonize with the facts observed, the public at once ascribed the epidemic to this meat, and the city authorities endorsed this assumption to divert attention from the waterworks. The state has now forbidden the sale of animals from the serum institute, but the ghost of that typhoid-inoculated horse, butchered and eaten, is invoked now by the irregulars on every possible occasion. The writer adds that considerable harm from this incident might have been avoided if the local physicians had refrained from disparaging criticism and sought to shield their confrères in the institute instead of joining in the cry against them.

Scarcity of Antitoxin in Buenos Ayres.—Dr. J. Penna is director of the isolation hospital at Buenos Ayres, and he expresses concern at the way in which antidiphtheria serum is being heralded and pushed there as a remedy for tuberculosis. He comments on the great harm that results when any remedy is advertised as a cure for tuberculosis. The poor consumptives, seeing the display ads of the pretended cure, waste their last and precious means in buying the advertised medicine, instead of keeping the money to make them more comfortable and to buy them nourishing food. He exclaims: "Is it not the height of cruelty thus to delude these unfortunates!" The present craze for antidiphtheria serum as a remedy for tuberculosis has exhausted the supply, and this condemns children with diphtheria to do without this potent remedy in the one disease for which it has proved its efficacy. He mentions specific instances, among them that of the child of very wealthy parents brought to the isolation hospital the day before as no antitoxin was to be obtained in town at any price, and it was known that there was still a small supply in this otherwise dreaded hospital. He adds that diphtheria is endemic in Buenos Ayres, and epidemics of it are not infrequent. While consumptives are trying the antitoxin, children are liable to be dying for want of it.

LONDON LETTER.

The Health of London in 1903.

The annual report of Sir Shirely Murphy, the health officer of the London County Council, for 1903, has just been published, and is highly satisfactory. As usual, it furnishes interesting figures. It is estimated that another 31,000 persons were added to the population of London, making a total of 4,613,812. The marriage rate was 17.4 per 1,000, a slight decrease since 1902, but more than in 1891, when it was 17.0, the lowest on record. The birth rate still continues to decline, and was only 28.4, the lowest on record. The death rate was 15.2, also the lowest on record. This remarkably low rate was not peculiar to London, and was partly due to favorable meteorologic conditions. The corrected death rate (16.5) is lower than that of any of the large towns except Bristol, which was 14.7, and compares favorably with foreign capitals, which show the following rates: Paris, 17.9; New York, 18.2; Rome, 19.8, and St. Petersburg, 23.8. By life table methods the health officer calculates that during 1903, compared with the decennium 1891 to 1900, there was a saving of 18,742 lives, representing a gain of 665,333 years of "life capital." The infant mortality was 130, one of the lowest recorded, and also lower than that of any other large town in England, except Bristol. Turning to the chief causes of death the greatest diminution was in diseases of the respiratory, nervous, and circulatory systems, and in diphtheria and phthisis. There was an increase in the deaths due to cancer, suicide, and diseases of the urinary system. Cancer was given as the cause of 4,695 deaths; the annual average of the preceding 10 years being 3,964. The rate per 1,000 living rose to 1.02.

Munificent Gift to the Royal College of Surgeons.

Mrs. Macloghlin, the widow of a deceased physician, has, in accordance with the intention of her husband, proposed to give $50,000 to the Royal College of Surgeons for the purpose of endowing scholarships in his memory. They are intended to assist young students in need of financial aid to proceed with their studies. The council of the college have gratefully accepted the offer and agreed to administer the trust which has been arranged by the presidents and vice-presidents in consultation with Mrs. Macloghlin.

The Dangers of Flannelette.

From time to time public attention is attracted to the dangers of flannelette by inquests on the bodies of persons who have been burnt in consequence of flannelette garments catching fire. The popularity of this material, however, does not appear to have been affected nor any means taken to combat the danger. In an editorial on the subject the *Lancet* says that the days of inflammable flannelette should be numbered. The death-rate roll of children who have been injured by its ignition is appalling. It catches fire and burns as easily as alcohol. The following is an example: A boy, aged 2 years, was left to play in a room while his mother was absent. He was clad in a flannelette nightshirt. The mother heard screams and returned to find the boy in flames. He was terribly burned. and died within twenty-four hours. The British government has requested coroners to make returns of these cases. One coroner states that last year he held no less than seventy-three inquests on children burned to death, a large proportion of the deaths being due to flannelette igniting. The *Lancet* very pertinently asks: "Why wait for more evidence; are not the returns sufficient?"

Correspondence.

Card Indexing for Preserving Useful Medical Information.

Philadelphia, Feb. 11, 1905.

To the Editor:—Among the difficulties which beset the physician is to preserve useful information on various subjects in systematic shape for ready reference. The best method of doing this, coming steadily into vogue, is the card index. Much of useful data is offered in the form of advertisements, prospectuses, book notices, booklets, leaflets, circulars or cards of irregular size, making it utterly impossible to arrange them comfortably, hence to preserve them in such a fashion that they can be readily consulted.

I made the suggestion long ago to the drug manufacturers that if they desired, or expected, us to bear in our minds descriptions of their preparations, some of which contain much merit, they should make it practicable by giving us printed information, much or little, on cards of the ordinary size used in the card indexes This is the best way.

Thus a card index could be kept especially for "therapeutic suggestions," notes on treatment gleaned from divers sources Some of the drug houses have adopted this suggestion, and are sending out cards containing a list of their special preparations which can be conveniently filed. Two sides of a card provide much space.

If the proprietors of the various sanitaria designed for rest or recuperation or special treatment would adopt the card index system in addition to their regular circulars, these would be put on file alphabetically under the heading "Sanitaria" or health resort, coastwise or mountain hotels, springs, spas, etc, and would thus be promptly called to the mind of the physician when groping vaguely to find a suitable place to send a patient for rest, recreation or special treatment. The same card index plan would serve publishers of books.

The card index system for keeping notes of cases is recognized to be the best which has so far been offered, likewise for the keeping of accounts and other matters requiring useful record.

These are now offered in such cheap convenient forms that there should be no difficulty in securing and keeping, and the possibility is thus made easy to systematize references so that various other data could thus be preserved in such a fashion that no important facts need be far distant from our daily work.

A single drawer in an ordinary desk could easily contain two such card indexes, at least in the forward end, and thus an ordinary desk of three or four drawers could be well equipped with six or eight card indexes.

There is too much labor in taking a blank card and writing out the data, but if cards were supplied suitably printed and black lettered which could slip in the proper alphabetical order, there would follow a great economy of time and trouble and attention, and an immense saving of useful information

J. Madison Taylor, M D

VALUE OF ALBUMOSURIA AS A MEANS OF DIAGNOSIS

Trenton, N J., Jan 10, 1905

To the Editor:—What d[illegible]ndence is to be placed on albumosuria as a means of diagnostica[illegible]g concealed pus in either of the great cavities, or in deep seated m[illegible]scular structures of the body? Please give the most reliable and a[illegible]urate test, or tests, for this substance in the urine

C. H Gordon, M D

Answer.—By albumosuria [illegible] meant the appearance in the urine of those higher soluble cleav[illegible]e products of the albumins which, though they are not coagulable, [illegible] can be removed from solution by "out-salting"—the so called "[illegible]lbumoses" Physiologic chemists distinguish two classes of albu[illegible]oses, the primary albumoses (protalbumose and heteroalbumose) [illegible]hich stand very close to the albumins proper, and the secondary or deuteroalbumoses which stand close to the peptones. The albumoses which occur in the urine appear to be chiefly deuteroalbumoses. The condition so often described as "peptonuria" is in the majority of cases really "albumosuria" The amounts of albumose in the urine vary from 0 06 to 0 6 per cent, the larger amount occurring usually in cases of empyema or croupous pneumonia. Albumoses occur in the urine in various pathologic circumstances The so called "enterogenous albumosuria" is met with in cases of ulcer of the stomach, ulceration of the intestine and carcinoma of the stomach. The so-called "pyogenous albumosuria" is encountered in various suppurative processes—large abscesses, empyema, croupous pneumonia, mixed infections with tuberculosis, etc The so-called "endogenous albumosuria" is met with where body-tissues are breaking down, e g, in phosphorus poisoning, in acute yellow atrophy of the liver, in carcinoma of the liver, etc Beside, deuteroalbumoses have been demonstrated in the urine in many febrile processes, e g, pneumonia, scarlet fever, influenza, diphtheria, measles, typhoid fever and tuberculosis. In order to be *absolutely* sure of the presence or absence of albumoses in the urine, especially of small amounts, it is necessary to remove any albumin, globulin, mucin or nucleo albumin that may be present But, roughly, for clinical purposes, the following preliminary tests may be made: (1) Heating acidified urine Heat five or ten c c. of urine to which a trace of acetic acid has been added in a test tube to boiling and filter hot If albumoses are present the filtrate becomes turbid, and this turbidity will increase on the addition of ammonium sulphate When the filtrate is cooled, add some caustic potash and one drop of copper sulphate solution (5 per cent.); if albumoses are present the reddish violet biuret reaction is obtained. (2) Ferrocyanid of potassium and acetic acid test. To 10 c c. of urine add 5 drops acetic acid, should a precipitate form (urates, mucin, etc.), filter and add from one to three drops of a 5 per cent solution of ferrocyanid *of potassium. If a precipitate forms, which vanishes on heating* to reappear on cooling, the presence of albumoses is demonstrated A safer clinical test is that of A. Jolles (Pharmaceutisches Centralblatt, vol xxxvii, 1896, p 432). About 10 c.c. of urine are thoroughly shaken with a little animal charcoal, the filtrate mixed with two drops of solution of lead acetate and filtered again If albumin is present, it should be first removed by adding a few drops of a 10 per cent. solution of acetic acid, boiling, *neutralizing with 10 per cent NaOH, shaking with animal* charcoal, filtering, precipitating with lead acetate and filtering again The filtrate is now free from urobilin and almost colorless; apply the biuret reaction Of the strictly scientific methods that of F. Hofmeister is as good as any. To half a liter of urine are added 10 c c of a concentrated solution of sodium acetate, and then, drop by drop, a concentrated solution of ferric chlorid until the fluid remains permanently red If the urine is strongly acid, it is nearly neutralized, then boiled and, after cooling, filtered The filtrate must contain no iron or albumin To this filtrate is now added one-tenth of its volume of concentrated hydrochloric acid and then an acid solution of phosphotungstic acid (200 grams phosphotungstate of soda and 120 grams phosphate of soda dissolved in 1,000 c c. water and 100 c c concentrated sulphuric acid added) as long as it continues to throw down a precipitate Collect the precipitate on a filter, wash it with a 5 per cent solution of sulphuric acid, rub it up while still moist with solid barium hydrate, add a little water, warm *for a short* time until the original greenish color is changed to pure yellow and then filter the mixture. Free the filtrate from barium by means of dilute sulphuric acid, concentrate the filtrate, make the solution alkaline, and add cautiously, drop by drop, shaking constantly, some diluted 1 per cent. solution of copper sulphate, *if albumoses be present, the biuret-reaction is obtained,* first a rose color and later a violet tint. If the urine contains mucin it should be first removed by the addition of a small amount of lead acetate solution The so called "Bence Jones body" is *often spoken of* as an albumose, but more recent studies have proved that it is a native albumin The best description of it is to be found in the article by Magnus Levy (*Ztschr. f. physiol. Chem.*, vol xxx, 1900, p 290) It occurs in the urine in cases of *osteomalacia, often* in very large quantities, sometimes as much as 6 7 per cent. If acid urine containing the Bence-Jones body be heated with a little concentrated solution of common salt to 50 degrees C, the urine first turns milky and at 60 degrees gives a *sticky (not flocculent)* precipitate, which adheres to the walls of the test tube or swims on the surface of the fluid. On heating further, the turbidity and precipitate disappear and the solution becomes *clear;* on cooling the albumin body *again separates* out, and under the microscope appears in the form of spheres, occasionally in the form of crystals That it is really an albumin (and not an alb[illegible]) is shown by the facts (1) that when pure it can be [illegible] *coagulated: (2) that with* alcohol it can be denaturalized, [illegible] that strong acids or alkalies convert it into acid albumin [illegible] albuminate, and (4) that on pepsin-digestion it yields the ordinary albumoses and peptone (with the exception of heteroalbumose). The diagnostic value of albumosuria is very slight except in conjunction with other symptoms. In case there were a deep-seated abscess anywhere, the leucocytosis and the "choppy" temperature chart would be far more decisive symptoms than the albumosuria. The presence of the Bence-Jones albumin is believed to be highly characteristic of osteomalacia.

A BOOK OF PORTRAITS OF PHYSICIANS.

In THE JOURNAL, July 2, 1904, page 43, we mentioned the fact that a number of readers had asked us for information concerning a circular letter which had been sent to those who had registered at the Atlantic City session of the American Medical Association, asking for photographs and subscriptions for a book of portraits of those in attendance at the session. We suggested caution in dealing with the firm, and we closed with the following comment: "We also call attention to the printed order blank which is to be signed ordering the engraving made. No charge for this is named, and there is a possibility of the charge being any amount the company wishes." Here the matter rested until recently, when, coming across some of the circulars which had been laid away for future reference, we wondered whether or not the book had been issued, and wrote to the company asking about it. We received no reply, but during the next few days two subscribers wrote us for information concerning the company, having paid for the book and never having received it. The statement of one of the two carries out the prediction which we made in the last sentence of our remark, July 2, which we have quoted above. He received a bill of $11 for the making of the engraving, this was from a separate company, and the order blank which was signed by the subscriber gives the company a perfectly legal right to collect the charge. On receipt of these letters we wrote to our representative in New York City, and he has reported absolute failure to get into communication with either the portrait company or the engraving company. They did not reply to his letters and could not be definitely located. The portrait company had moved to a new address, but on calling at the new address our representative found no one connected with the firm and no equipment was apparent, but he was told that mail would be forwarded. The result of his search for the engraving company was similar. The person who stated that mail would be forwarded also stated that the book referred to had been issued, but, because certain men had objected to receiving it because some of the prominent men of the Association had not been included, another edition was expected soon with those men included. If any one has received the book we would appreciate being informed to that effect.

SUGGESTIVE THERAPEUTICS.

L. E. H. asks: "What are the best works on suggestion, its practice, etc.? Is there a place of good standing where this branch of study is taught?"

H. J. N. asks for the address of any school which gives instruction in hypnotic suggestion, with the cost and time needed for the course. "If no such school exists, please give names of authorized works on the subject."

ANSWER.—The question of suggestion and its practice has been exhaustively reviewed, as far as current medical literature is concerned, in the "Practical Medicine Series of Year Books, Chicago, Vol. VIII, 1903, and Vol. VIII, 1904. Works of value on the subject are: "Influence of the Mind on the Body in Health and Disease," Daniel Hack Tuke, M.D., 1884. "Suggestive Therapeutics," H. Bernheim, M.D., 1889. "Hypnotism and Suggestion," by Osgood Mason, M.D., 1901. "The Force of Mind or the Mental Factor in Medicine," A. T. Schoefield, 1902. "Psychotherapy in Practice of Medicine and Surgery," S. Leavitt, M.D., 1903, and a very excellent article by F. X. Dercum, M.D., in Vol. VIII of "System of Physiological Therapeutics." We know of no place in good standing where this line of study is specially taught, but more or less attention is usually given to it by the professors of therapeutics.

DEADBEAT LIST.

GALESBURG, ILL., Feb. 17, 1905.

To the Editor:—Any information or advice on the best method of procedure in forming a physicians' "delinquent list" will be gratefully received by the undersigned. Members of the Knox County Medical Society feel that there are many professional deadbeats who are imposing on them, and what we want is some plan which will be legal, not cumbersome, and which at the same time will protect us from the undeserving.

WILLIAM H. MALEY.

SCHOTT TREATMENT OF CHRONIC HEART DISEASE.

C. W. A. can obtain a copy of Dr. Bezly Thorne's book, "The Schott Methods of Treatment of Chronic Diseases of the Heart" (referred to by Dr. Anders in THE JOURNAL, Jan. 14, 1905), from Blakiston's Son & Co., Philadelphia. The price is $2.00.

Marriages.

AUGUSTUS KORNDOERFER, M.D., to Miss Mary M. Jones, both of Philadelphia, February 1.

WILLIAM E. DOWNING, M.D., Suison, Cal., to Miss Baugh of San Francisco, January 31.

RUSSELL C. MCNEILL, M.D., to Miss Anna Blair, both of Bellecenter, Ohio, January 25.

CLYDE J. SAYLOR, M.D., Womelsdorf, Pa., to Miss Rena A. Miller of Lebanon, Pa., January 31.

BOYD W. SCHAFFNER, M.D., Templeton, Pa., to Miss Grace Fearl of Johnstown, Pa., January 24.

CHARLES THADDEUS BELL, M.D., to Miss Esther Hampton Brock, both of New York City, January 30.

JOSEPH H. HATHAWAY, M.D., Rochester, N. Y., to Miss Ethel H. S. Baird of Woodstock, N. B., January 25.

R. MARVIN WINN, M.D., Sawrton, Mo., to Miss Rebecca Jones of Ashburn, Mo., at Louisiana, Mo., February 1.

BELLE F. ORR, M.D., Belton, Mo., and ROBERT A. WILLIAMS, M.D., Washington, Kan., at Kansas City, Mo., January 26.

Deaths.

Michael O'Hara, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1852, a member of the American Medical Association, died at his home in Philadelphia, January 31, aged 72. He served as assistant surgeon in the United States Navy, and as surgeon of the One Hundred and Fiftieth Pennsylvania Volunteer Infantry during the Civil War; was attending physician for many years to St. Mary's Hospital and the House of the Good Shepherd; from 1894 to 1898 he was director of St. Agnes' Hospital. He served as vice-president and librarian of the Philadelphia County Medical Society, and in 1876 he was a delegate to the International Medical Congress.

Freeman Dwight Case, M.D. Cleveland Medical College, Medical Department of Western Reserve College, 1870, a member of the American Medical Association, a member of the Ashtabula City council for several terms, and an organizer and member of the executive board of the Ashtabula General Hospital; a member of the Ashtabula County Medical Association, died at his home in Ashtabula, February 7, from septicemia following a fall in December last, in which he injured his knee and leg, aged 58.

T. H. Brenneman, M.D. University of Virginia Medical Department, Charlottesville, 1900, house surgeon of the Princess Anne Hotel, Virginia Beach, Va., a member of the local and state medical societies, died from septicemia following an operation wound, January 28, at Sarah Leigh Hospital, Norfolk, Va., after an illness of six weeks, aged 34.

Mary Alice Brownell, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885, a member of the American Medical Association; for nine years a physician in the State Custodial Asylum, Newark, N. Y., and afterward a practitioner in that village, died in the Rochester City Hospital, January 30, after an operation, aged 40.

George K. Rodebaugh, M.D. Jefferson Medical College, Philadelphia, 1901, house physician of the Park View Sanitarium, Columbus, Ohio, and for a time professor of practice of medicine in the Ohio Medical University, died at his home in Columbus, February 6, from nephritis, after an illness of more than a year, aged 27.

Frederick P. Tuxbury, M.D. Dartmouth Medical School, Hanover, N. H., 1899, died at his home in Denver, Colo., February 5, from nephritis, after an illness of ten days, aged 37. At a special meeting of the Denver City and County Medical Society, February 7, resolutions of regret and respect were adopted.

William H. Risk, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1866, president of the Summit (N. J.) Board of Health for two years, and a member of the county and state medical societies, died at his home in summit, February 7, after a long illness, aged 62.

Clarence W. DeLannoy, M.D. Jefferson Medical College, Philadelphia, 1881, chief surgeon of Telluride City Hospital, and health commissioner of the city, died at his home in Telluride, Colo., February 7, *from septicemia due to an operation* wound, after an illness of four months, aged 50.

Humphrey B. Anderson, M.D. Detroit (Mich.) College of Medicine, 1888, a member of the American Medical Association; a charter member and at the time of his death president of the Grand Traverse Medical Association, died at his home in Traverse City, Mich., February 8, aged 46.

Richard G. Lightle, M.D. Kentucky School of Medicine, Louisville, 1898, under indictment for defrauding life insurance companies of $21,000, burning a barn, and robbing a grave, died at the home of his mother in Searcy, Ark., February 7, from pneumonia.

William S. Wheelwright, M.D. Rush Medical College, Chicago, 1878, of Belleville, Wis., suffered a cerebral hemorrhage while making a professional call at New Glarus, and died four days later, February 5, aged about 60.

John H. McBrayer, M.D. Atlanta (Ga.) Medical College, 1882, died at his home in Shelby, N. C., January 30, from nephritis, after an illness of several years, aged about 60. He served as *postmaster of Shelby for two terms.*

Addison R. Tarkington, M.D. *Memphis (Tenn.) Hospital* Medical College, 1891, of Hot Springs, Ark., died at Benton, Ark., while on his way to San Antonio, Texas, for his health, from an affection of the throat.

Emmett A. Sprowls, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1898, formerly a practitioner of Claysville and West Alexander, Pa., died at his home in Elgin, Ill., February 1, aged 30.

Howard Edgar Bowman, M.D. State University of Iowa College of Medicine, Iowa City, 1904, died at his home in Hills, Iowa, February 1, from pneumonia, after an illness of ten days, aged 39.

Thomas Hill Ellis, M.D. Medical College of South Carolina, Charleston, 1894, died at his home in Hartsville, S. C., Dec. 26, 1904, from typhoid fever, after an illness of three weeks, aged 33.

James McGregor Stevenson, M.D. McGill University Medical Department, Montreal, 1856, died at his home in Denfield, Ont., January 31, from pneumonia, after an illness of two days, aged 67.

James David Hoyl, M.D. Harvard University Medical School, Boston, 1857, died at his home in Fort Valley, Ga., Dec. 26, 1904, from chronic bronchitis, after an illness of one year, aged 70.

Frank H. Sims, M.D. Atlanta (Ga.) Medical College, 1883, of Atlanta, Ga., died at the Elkin-Cooper Sanitarium in that city, February 5, from pneumonia, after an illness of a few days, aged 42.

Francis Norton Phelan, M.D. University of Wooster Medical Department, Cleveland, 1884, died at his home in Duluth, Minn., February 11, from pneumonia, after an illness of a few days.

Sidney M. Abbay, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1866, of Centerville, La., died at the sanitarium in Franklin, La., February 6, aged 67.

John B. McEwen, M.D. University of Nashville Medical Department, 1861, thrice treasurer of Lafayette County, Miss., died at his home in Oxford, February 6, from pneumonia.

E. M. Schelde, M.D. College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1904, died at Blooming Prairie, Minn., from consumption, January 25, aged 36.

Albert O. Mundhenk, M.D. Medical College of Ohio, Cincinnati, 1903, of West Alexandria, Ohio, died in Denver, February 6, from tuberculosis, *after an illness of a year*, aged 30.

Allen F. Hagadorn, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1875, died at his home in West Bay City, Mich., February 8, from apoplexy.

Edson H. Young, M.D. University of Vermont Medical Department, Burlington, 1884, *died at his home* in Buffalo, N. Y., February 5, after an illness of one week, aged 44.

Edward Dudley Arnold, M.D. Rush Medical College, Chicago, 1878, died at his home in Omaha, February 5, from pneumonia, after an illness of six days, aged 46.

Wooster Beach Preston, M.D. Cincinnati, 1867, died at his home in Dansville, N. Y., February 4, after an illness of more than a year, from Bright's disease, aged 60.

George W. Ebrite, M.D. Dartmouth Medical School, Hanover, N. H., 1868, died suddenly at his home near Gainesville, Mo., January 14, from angina pectoris, aged 64.

Jacob A. Gilder, M.D. New Orleans School of Medicine, 1868, a pioneer of Beaumont, Texas, died in that city, February 4, after an illness of six months, aged 67.

Moses M. Curtis, M.D., certificate, died at his home in Miles Station, Texas, January 10, from the rupture of an aneurism, *after an illness* of two weeks, aged 63.

Augusta Smith, M.D. Chicago, 1883, was struck by an electric car near her home in St. Louis, February 4, and died a few hours later from her injuries, aged 73.

James Madison, M.D. State Board of Health, 1878, a pioneer of Clark County, Ill., died at his home near Marshall, February 2, *from senile debility*, aged 83.

James A. Freer, M.D. New York, 1885, of Washington, D. C., was found dead in a country inn near that city, February 5, from morphin poisoning, aged 46.

Alfred Lindsay Shapleigh, M.D. Harvard University Medical School, Boston, 1894, a medical missionary in China, died in Shanghai, February 3, aged 35.

Jacob L. Gebhart, M.D. *University of Heidelberg*, Germany, died at his home in Hot Springs, Ark., February 3, from senile debility, aged more than 80.

Joseph N. Hetzler, M.D. Medical College of Ohio, Cincinnati, 1875, died *at his home in Celina, Ohio, from cerebral* hemorrhage, February 6, aged 76.

Albert G. Anthony, M.D. Ohio, 1880, died from the effects of carbolic acid taken with suicidal intent, at a hotel in Syracuse, N. Y., February 1, aged 45.

John Schmidt, M.D. *Marion Sims College of Medicine*, St. Louis, 1898, died at his home in St. Louis, February 6, after a lingering illness, aged 29.

George W. Yokum, M.D. Jefferson Medical College, Philadelphia, 1854, died at his home in Beverly, W. Va., January 30, after a protracted illness.

Don Quincy Sims, M.D. 1850, of Joshua, Texas, died at Morgan, Texas, December 17, from brain disease, after an illness of three months, aged 78.

Thomas J. Robinson, M.D. University of Louisville (Ky.) Medical Department, 1869, died at his home in Marianna, Ark., January 15, aged 63.

Samuel E. Thayer, M.D. University of Buffalo Medical Department, 1869, died at his home in Hamilton, Mass., February 5, aged 62.

Baxter Haynes, M.D. St. *Louis College of Physicians* and Surgeons, 1880, died at his home, Harricane, Ill., January 27, aged 77.

Patrick H. Kelly, M.D. Medical College of Ohio, Cincinnati, *1850, died at his home in Waterford, Ohio, February 6, aged 80.*

Samuel R. Woods, M.D. St. *Louis Medical College*, 1867, died at his home in Clearwater, Fla., January 23, aged 75.

William D. Babcock, M.D. New York, 1885, of East Hampton, Conn., died in Florida, February 1, aged 57.

Benjamin F. Cory, M.D. Cincinnati, died at his home in *Takoma Park, D. C., January 27, aged 85.*

Royal R. Lacey, M.D. Cincinnati, 1878, died at his home in Carbondale, Ill., February 2, aged 68.

Book Notices.

TEXT-BOOK OF INSANITY BASED ON CLINICAL OBSERVATIONS, for Practitioners and Students of Medicine. By Dr. R. von Krafft-Ebing, late Professor of Psychiatry and Nervous Diseases in the University of Vienna. Authorized Translation from the Latest German Edition by Charles Gilbert Chaddock, M.D., Professor of Diseases of the Nervous System in the Marion-Sims-Beaumont College of Medicine, Medical Department of St. Louis University, St. Louis. Pp. xvi—638. Price, $4.00 net. Philadelphia: F. A. Davis Company. 1904.

Those who have had the rare pleasure of listening to Krafft-Ebing's remarkably clear exposition of psychiatric types and later have drawn from the clinical riches of his text-book will rejoice that readers of English are to be introduced to this great descriptive writer. For many years his work has been a standard text-book and nowhere are to be found better word pictures of the various symptom-groups of insanity. It is essentially clinical. Even the 230 pages on the "General Pathology and Therapy of Insanity" are practical, the matter evidently being the product of experience with insane people. Krafft-Ebing has shown neither the analytic nor synthetic power of Kraepelin, but no writer has known better how to put the reader in the place of one who visits an asylum, sees the faces of the patients, observes their acts, hears their talk and then follows their course day by day. Indeed, there is very little of what an asylum physician may see and learn in years of active service that is omitted from this text-book. The amount of information contained in the six hundred and twenty-odd pages is astonishing. Notwithstanding the completeness of the work, it can not to-day fill the demands of the student of psychiatry. Live and serious questions as to the nature of certain forms of insanity have arisen; questions involving diagnosis, prognosis and treatment: questions not broached in the work before us. Notably the practical issues in connection with dementia præcox, so-called manic-depressive insanity and paranoia, not to mention Korssakow's psychosis, are entirely ignored. This being the case, it is to be regretted that the translator did not also assume the prerogative of editor and add some discussion of new matter brought into the psychiatric field by observers and writers other than the author. The translator has done his work well and has earned the gratitude of many.

Normal Histology and Microscopical Anatomy. By Jeremiah S. Ferguson, M.Sc., M.D., Instructor in Normal Histology, Cornell University Medical College, New York City. With 462 Illustrations in the Text, Many in Colors. Cloth. Pp. 738. Price, $5.00. New York and London: D. Appleton & Co. 1905.

This book appears to cover in a satisfactory manner the field it occupies. Perhaps more space, relatively speaking, than usual has been devoted to special organ systems, especially the nervous system. The illustrations are in general creditable. Figures 165 and 361 should be replaced by other and better ones in the next edition. There is a very limited chapter on technic which might as well have been omitted in view of the various authoritative books on histologic technic now obtainable and copies of some of which surely are present in every well-equipped laboratory. It is somewhat startling to read in the preface that the field of normal histology is inadequately covered as regards text-books. This becomes still more puzzling when we find that in his list of references the author cites nearly a dozen works that have been issued since 1900 and several of which are recognized as standard text-books. Dearth of books dealing with normal microscopic anatomy and histology is, therefore, hardly an adequate reason for a new book on this subject. In this case, however, it seems as if the author had a real interest in his subject and that his book, which has been prepared with care, will be found useful.

Bacteriology and the Public Health. By George Newman, M.D., F.R.S.E., D.P.H., Formerly Demonstrator of Bacteriology in King's College, London. Illustrated. Third Edition. Cloth. Pp. 497. Price, $5.00. Philadelphia: P. Blakiston's Son & Co. 1904.

Several new chapters have been added to this book, and the whole revised and enlarged. The book aims to give a simple general statement of our present knowledge of microbiology in relation to public health for the special benefit of the general student of hygiene and of the medical officer of health. Inasmuch as malaria and other diseases caused by microbes, other than bacteria, in the usual sense of the word, are considered, objection might be made to the present title. Microbiology would seem to fit the case better. Take it all in all, the book is well written and has a distinct field of usefulness. We think that the account given of yellow fever is unsatisfactory because of the relatively large amount of space given to Sanarelli's bacillus and the wholly inadequate statement of the significance and the results of the work of Reed and his colleagues. The citation of streptococcus and pneumococcus infections as good examples of the value of antitoxic treatment is, of course, not in accord with our present state of knowledge. Lobar or croupous pneumonia is said to be associated with two organisms, "Fränkel's diplococcus and Friedländer's pneumobacillus," a statement that one would least expect to meet in this place. The "ray fungus" is given the absurd name of "streptothrix actinomyces." The bacteriology of sewage, soil and feed seems to be discussed very satisfactorily.

Miscellany.

WINNIPEG TYPHOID EPIDEMIC.

Expert's Report to the Municipal Authorities on the Causes and His Recommendations for Future Prophylaxis.

An excessive prevalence of typhoid fever is no new thing in Winnipeg. Table 1 shows the death rates calculated from the cases and the deaths reported to the city board of health and from the deaths reported to the Department of Agriculture through the office of the city clerk.

Table 1.—Cases and Death Rates from Typhoid Fever in Winnipeg.

Year.	Est. Pop'n.	Cases.	Death Rate per 10,000 Pop'n. Bd. of Health.	Death Rate per 10,000 Pop'n. Dep't of Agricult.
1900......	42,500	582	7.99	11.75
1901......	44,800	319	8.01	11.83
1902......	48,400	356	5.99	9.50
1903......	56,700	409	8.11	8.48
1904......	67,300	1,276	10.74	21.85

Whichever mortality record be accepted as more nearly correct, it is apparent that the death rate from typhoid fever in Winnipeg has for some years been in marked excess, and in 1904 in alarming excess, as compared with that in the majority of other American and European cities. This is true, even if the population estimate be increased 20 per cent. in the years named and the death rate correspondingly lowered. To facilitate comparison, recent average death rates for a number of other cities are given in Table 2.

Table 2.—Typhoid Death Rate of Various Cities.

City.	Death-rate per 10,000 Pop'n.	City.	Death-rate per 10,000 Pop'n.
Lawrence	2.0	Louisville	6.0
Albany	5.1	Milwaukee	1.8
Baltimore	3.5	Minneapolis	3.9
Boston	3.0	New York	1.9
Buffalo	2.7	Omaha	2.8
Chicago	2.8	Philadelphia	5.4
Cincinnati	3.5	Pittsburg	10.6
Cleveland	4.0	Providence	2.4
Columbus	3.1	St. Louis	2.3
Denver	3.8	St. Paul	2.3
Fall River	1.5	San Francisco	3.7
Detroit	1.9	Washington	8.8
Indianapolis	3.8	Berlin, Germany	0.5
Jersey City	2.4	London, England	1.4
Kansas City	3.1	Hamburg, Germany	0.9
Los Angeles	4.3	Rotterdam, Holland	0.2

A critical examination of the available data in Winnipeg showed an interesting and significant distribution of the cases both in time and space. It soon became evident that several factors had conspired to produce the abnormally large amount of typhoid fever that occurred in Winnipeg in 1904. For the sake of clearness these may be considered under separate heads.

I. CONTACT INFECTION.

A very serious feature of the situation in Winnipeg is the occurrence of a large number of cases in house groups. In perhaps the majority of dwellings in which typhoid fever appeared, the first case was followed more or less promptly by other cases in the same household. In nearly all instances in which more than one case occurred in a house the dates of infection are such as to point unmistakably to a more or less direct transfer of the specific disease germ from the individuals first attacked to other members of the household.

The reason for this is that the typhoid bacillus may multiply in the body of the patient in immense numbers. Both the discharges from the bowels and from the bladder may contain countless millions of living microbes, and a very small amount of infectious material, therefore, is capable of infecting many persons. One element of peculiar danger is the fact that typhoid germs occasionally persist in the urine of typhoid convalescents for weeks and even months after complete recovery has taken place. Special vigilance is necessary to combat the peril from this source.

Abundant evidence has been secured that in Winnipeg, as in

[Editor's Note.—The typhoid epidemic in Winnipeg, Manitoba, has been mentioned from time to time in our news columns. The municipal authorities of Winnipeg engaged Edwin O. Jordan, associate professor of bacteriology in the University of Chicago, to make an investigation of the situation. This article is an abstract of his official report, presented to the Winnipeg City Council, Feb 8, 1905.]

many other American cities, the household precautions against the spread of infection from case to case have not been as rigorous as is desirable. In some instances food has been prepared for the members of a family by the individual who was at the same time performing some of the duties of nurse to a typhoid fever patient. Members of a patient's family and even outside visitors have in some instances associated more or less freely with a patient or convalescent, and in more than one household disinfection of the excreta and of the bedding and other articles used by the patient has not been carried out with the rigor necessary to stamp out all trace of infection.

[As an illustration of the nature of the precautions considered essential by modern authorities, Mr. Jordan quoted the regulations of the German government concerning the supervision of typhoid fever cases. We omit this from the abstract.—Ed.]

II. LACK OF SEWER CONNECTIONS.

The large number of outside privies in Winnipeg is undoubtedly favorable to the maintenance of typhoid fever, and in the past has been largely responsible for the prevalence of the disease in the warmer months of the year. Winnipeg contains approximately 12,000 buildings, and only 5,600 sewer connections. Some of these privies must occasionally be used by persons suffering from mild or unrecognized cases of typhoid fever or by convalescents. Under the conditions that prevail in more than one section of the city the transfer of infectious material from these outhouses to the dwellings and to the persons of neighbors is not only possible, but in greater or less degree certain to occur. Fecal material from some of these privies was seen scattered over the whole width of the alley. Children play in the alleys on which these privies abut, and may readily soil their shoes, clothing and even fingers with infectious material. Dogs and other animals may convey infection into houses in various ways.

Perhaps the most mischievous carrier of infection under the circumstances described is the common house-fly. It has been repeatedly shown that this pestiferous insect is a common purveyor of infection. The house-fly is bred in large numbers in horse manure, and the intermingling of stables and privy vaults seen in some of the back lanes of Winnipeg affords peculiarly favorable conditions for the spread of infection by this means.

The past history of typhoid fever in Winnipeg bears out this plain inference from the sanitarry conditions. During the five years for which record has been obtained, typhoid fever has prevailed most extensively in August, September and October, the very months when infection in the ways indicated would be most likely to take place. The local distribution of cases is wholly in accord with the assumption of this mode of infection.

III. MILK INFECTION.

A house-to-house canvass[1] showed that many more cases developed in families supplied with milk from some milkmen than from others. It must not be forgotten that in every locality where typhoid fever is prevalent and where opportunities for infection are so numerous as they have been in the city of Winnipeg in the last six months, infection of some one or more of the milk supplies is not only probable, but almost certain to occur. This is one of the recognized evils that follow in the wake of a great accumulation of infectious material in a community. Danger from this source can be much diminished, however, by frequent inquiry into the health of those engaged in producing and distributing the milk, and especially by preventing the infection of the milk or of the milk vessels en route.

IV. WATER SUPPLY.

The main water supply of Winnipeg, derived from an artesian well, has been frequently tested in the past by competent analysts, and with uniformly favorable results. There is nothing in the sources of this water, in the softening treatment to which it is subjected, or in its epidemiologic relations, to cast suspicion on its wholesomeness. The water of the Assiniboine River, however, which has been used at times as an accessory source of supply, comes from a watershed exposed to pollution at many points, and it has been generally recognized that the use of raw Assiniboine water was to be avoided as much as possible. On two occasions, in 1904, raw Assiniboine water was turned into the city mains to increase the inadequate supply and to meet the emergency caused by large fires. Examination of a table of the reported cases of typhoid fever tabulated by weekly and fortnightlty periods, reveals several very interesting facts. There is noted first a rapid rise in the amount of typhoid fever, reaching its maximum in September, at the time when fly infection might reasonably be supposed to manifest its greatest effect. A decline in the number of cases reported then sets in precisely as was the case in four preceding years. This decline is abruptly checked in the fortnight October 24 to November 6, when the number of cases reported rises to 110 as compared with 83 in the preceding fortnight. In the succeeding bi-weekly periods the decline again continues with considerable regularity until in the period December 19 to January 1 a minimum of 45 cases is reached. Instead of continuing to decline, however, a striking increase of almost explosive character is shown in the next fortnight when the cases reported registered 120. It is a highly suspicious circumstance that the dates on which the Assiniboine water was pumped into the city mains, namely, October 10 and December 28, correspond with the dates of probable infection of the cases reported in the two periods referred to.

Supposing, however, that infected water played no part in the production of typhoid fever on the occasions mentioned, it must be strongly emphasized that even the occasional use of the raw Assiniboine water is an unwholesome and dangerous practice. Bacterial examinations made by the writer of the river water collected at the intake of the pumping-station showed the presence of fecal bacteria in the water in considerable numbers. On days when the Assiniboine water was being pumped, water drawn from the taps in the southern portion of the city showed likewise the presence of fecal bacteria. The northern portions which, from their location, were presumably receiving chiefly or wholly water from the artesian well, did not contain any objectionable bacteria in the tap water at the time the examination was made.

OTHER CONSIDERATIONS.

The condition of the city sewers in Winnipeg has been such as to give rise to the conjecture that the emanations from the manholes or from defective plumbing might account in some way for the prevalence of typhoid fever. It is difficult, however, to find support for this view in the known facts of typhoid epidemiology; and the ascertained facts regarding the distribution of typhoid fever in Winnipeg lend no countenance to the view that sewer air has been a direct means of transmission in the present outbreak.

At the same time, it must be remembered that the highly offensive stenches arising from decomposing matter in sewers have often been shown to exercise a depressing and weakening influence on human vitality. It is in some such way, if at all, that we must conceive the peculiar condition of the Winnipeg sewerage system to have influenced the spread and maintenance of typhoid fever.

---

[1] Incidentally, this canvass showed that in this particular district only 70 out of 89 cases had been reported to the Board of Health, or about 78 per cent. of the number actually existing. If the same ratio was maintained throughout the city, several hundred cases of typhoid fever actually occurred of which the Board of Health received no record. Furthermore, it must be noted that the dates on which the cases are reported to the Health Office are in some instances not to be taken as the dates of inception of the disease. Twenty-five cases that had been reported to the Board of Health but regarding which more accurate information was obtained by canvass, were selected at random for comparison. Seven of these had been reported to the Board of Health within three days after the beginning of the disease, so far as the latter could be fixed by the date of taking to bed and summoning a physician; eight more were reported within ten days, and the remaining ten cases were not reported to the Board of Health until 10 to 15 days had elapsed. From these facts it can be readily seen how greatly the work of local officials must be hampered by the lack of precise information concerning the occurrence and date of onset of the disease. Prompt action on the part of the health authorities would be greatly aided by a further systematization in the methods of reporting and supervising cases of typhoid fever. In any attempt to combat further epidemic spread, the advantages of a full knowledge concerning the occurrence and distribution of all cases is so obvious as hardly to need comment.

No reason was found for attaching suspicion to the ice supply.

In view of the facts that have been instanced regarding the frequency of contact infection, it is desirable to emphasize once more the multifarious ways in which infection can occur when once typhoid fever has become firmly established in a community. During the whole course of the illness and often far into convalescence immense numbers of typhoid bacilli leave the body of the patient. The dangers to which the whole community is exposed from unrecognized or unsupervised cases of typhoid fever are therefore countless. Almost any raw foodstuff may be the vehicle for infection. Milk, butter, raw vegetables, fruit, bread, if handled by typhoid convalescents or peddled by persons dwelling in infected houses, may become a means of spreading the disease. Under some conditions it is apparent that laundries may aid in dissemination of the infection. In short, it is unnecessary to enumerate all the possible ways in which infection can be transmitted, and typhoid fever become fastened to the shoulders of a community as an endemic disease. Experience and common sense will serve to point the way to these dangers and to discover means for their avoidance Thorough disinfection is the key to the situation.

SPECIFIC RECOMMENDATIONS.

1. To deal with the prevention of contact infection the health officer should be in the possession of ample power and financial resources for isolating, disinfecting and carrying out such other measures as are in his judgment necessary to prevent spread of the disease from the case under supervision. Every fresh case of typhoid fever is a new focus of infection, and unless stringently controlled, is a more or less direct menace to the whole city. Prompt notification of new cases is imperative.

2. In those parts of the city where sewers exist, connection of all houses with the sewers should be enforced and that as speedily as practicable. Until such time as this is accomplished, temporary measures, such as thorough disinfection with milk of lime, should be promptly applied. Of foremost importance is the abolition of the open outhouses It is evident that it is not consonant with the public safety that any person ill with typhoid fever should be allowed to remain in a house without sewer connection.

3 Milk-measuring vessels or general receptacles of any sort should not be carried into or removed from houses in which typhoid fever is present The daily delivery of milk must be made with suitable precautions Inspection of the sources and routes of milk supply can not be too vigilant at times when typhoid fever is known to prevail.

4 The existence of private wells renders efficient control of the city's drinking water more difficult than if a single source of water supply existed. The use of such wells should be restricted and their number reduced as rapidly as possible. It should be made physically impossible for the employes of the Canadian Pacific Railway Company and for those of the City Railway Company to draw water for drinking purposes from taps connected directly with the Assiniboine or Red River. Experience under similar conditions in many cities has shown the futility of merely providing hortatory placards. In this connection it may be once more pointed out that a single case of typhoid fever due to drinking impure water may become a center from which scores or even hundreds of other cases will arise.

Water from the Assiniboine River should be used as little as possible.

5 I would recommend finally the employment of a man who has had experience in the management of epidemics to take charge of the whole situation, and to institute and enforce the necessary measures for stamping out all traces of infection.

In conclusion, I wish to acknowledge my deep obligation for the effective assistance rendered during the investigation by the various municipal departments and officials who have placed at my disposal all available data, and to express especially my indebtedness to Dr. Gordon Bell, who has afforded me valuable laboratory facilities and has greatly aided me in various ways.

The Downfall of Therapeutics.—The following editorial from *American Medicine* shows clearly the present status of therapeutics and materia medica: "Before the development of the natural sciences placed medicine as an art among the applied sciences, therapeutics was the most important branch of medical study and practice. Among the medical sects the same observation holds true at the present time. During the last half century medical progress, however, the pursuit of exact medical knowledge, has led students chiefly into surgery, diagnosis, pathology and bacteriology. Definite knowledge of the intimate reactions of the metabolic processes of our bodies with foreign agents introduced as drugs is just coming into sight with the growth of the new science of pharmacology, and so necessarily therapeutics at present lags behind. All of which is new to no one who sees, and is introduced simply to draw attention to an unfortunate practical result of this state of affairs. For some years progress in materia medica and therapeutics has seemed almost to lie in the hands of lay manufacturers. With their new compounds and their disguised old ones, the drug makers have kept the materia medica expanding at an alarming rate. This condition is by no means wholly to be deplored, as the pharmaceutists have contributed much to the comfort of physician and patient. However, the tremendous preponderance of commercialism in recent therapeutic progress has brought with it some ill conditions Money-making attracts the unscrupulous, and the medical profession has difficulty in separating the wheat from the tares. Any good new laboratory product of therapeutic value is immediately imitated or attacked. There develops intense feeling between foreign and domestic manufacturers, and all the while the poor doctor, as the bone of contention, is overwhelmed with 'literature' and 'medical journals' (*sic*) and agents. Contradictions multiply until mercury and quinin appear to be about the only agents of whose qualities the physician may feel reasonably sure! The *prize*—the patronage of the profession—being of great commercial value, many subterfuges are employed by some to enable them to share in it Official positions in medical bodies at times are sought, and at other times are appropriated by not too nice strategy. Medical journals are subsidized and new ones are published. A number of makers pay a regular stipend secretly to complaisant doctors here and there over the country, who, in return, are expected to read 'useful' papers and at every possible turn to uphold the wares of the benefactor. Thus it comes that therapeutics has reached its present low estate. Scientific physicians give their time to diagnosis and pathology, and limit themselves to simplest measures of treatment. Others make a diagnosis and then choose the remedy that the maker says is best for that condition. Many among us who love the study of means to alleviate suffering have endeavored faithfully to recreate professional interest in pure therapeutics, but the combat with intrenched wealth and monopoly is an unequal one in the face of general professional lethargy. But hope is not to be abandoned."

Sudden whitening of the hair is well authenticated, being known for centuries as recorded poetically by Byron in the "Prisoner of Chillon," says the *Med. Times*. Darwin tells of a man who, while being led to execution, became gray before the eyes of the spectators. Laycock records the case of a Sepoy who became gray in a half-hour. Cantrell reported an interesting case in his clinic, a man of 45, whose moustache became white in twenty-four hours and in ten days his whole head of hair changed its color to white. Brown-Séquard watched his own hair change; it occurred so rapidly that he could note the change daily. Henry of Navarre had his hair change in twenty-four hours.

State Boards of Registration.

COMING EXAMINATIONS.

Connecticut Medical Examining Board, City Hall, New Haven, March 14-15. Secretary, Charles A. Tuttle, M.D., New Haven.

Massachusetts Board of Registration in Medicine, State House, Boston, March 14-15. Secretary, Edwin B. Harvey, M.D., Boston.

Maine Board of Medical Registration, City Building, Portland, March 28. Secretary, Wm. J. Maybury, M.D., Saco.

District of Columbia January Report.—Dr. W. C. Woodward, secretary of the Board of Medical Supervisors of the District of Columbia, reports the examination held at Washington, Jan. 12, 1905. The number of subjects examined in was 17; total number of questions asked, 80; percentage required to pass, 75. The total number examined was 14, of whom 12 passed and 2 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Columbian University	(1904)	82.06, 83.31, 79
Georgetown University	(1904)	85.03
Howard University	(1903) 75.18(1904)	79.68*, 81.31*
Johns Hopkins University	(1902)	86, 88.09
University of Pennsylvania	(1883)	92.18
University of Virginia	(1901)	96.18
Woman's Med. Coll. of Pennsylvania	(1903)	95.15
FAILED.		
Georgetown University	(1904)	74.18
Howard University	(1904)	60.08

*Second examination.

Iowa Report for 1904.—Dr. J. F. Kennedy, secretary of the Iowa State Board of Medical Examiners, reports the written examinations held at Des Moines during 1904. At each examination the number of subjects examined in was 8; total number of questions asked, 80, and percentage required to pass, 75. At the examination held in April, 80 persons were examined, of whom 69 passed and 11 failed. The following colleges were represented:

PASSED. College.	Year Grad.	Per Cent.
Barnes Medical College, St. Louis	(1903)	75
College of P. and S., Baltimore	(1902)	87
College of P. and S., New York City	(1891)	87
Ensworth Medical College, St. Joseph, Mo	(1904)	76, 77, 81
Creighton Medical College, Omaha, Neb	(1901)	77
College of P. and S., Keokuk, (1904) the grade of 75 was reached by one, 76 by two, 77 by five, 78 by one, 79 by three, 80 by three, 81 by two, 82 by three, 83 by three, 84 by five, 85 by two, 86 by three and 87 by four.		
McGill University, Montreal, Canada	(1903)	88
Rush Medical College, Chicago, (1895) 90, (1901) 87, (1903) 85, 86, (1904) 85.		
Coll. of P. and S., St. Louis, (1902) 75, (1903) 78,	(1904)	88.89
Sioux City College of Medicine, (1904) the grade of 81 was reached by one, 82 by one, 84 by two, 85 by one, 86 by one, 87 by three, 88 by one, 89 by one and 90 by one.		
University of Iowa	(1897)	81
University Medical College, Kansas City, Mo	(1903)	76
University of Michigan	(1894)	87
FAILED.		
Homeopathic Medical College, St. Louis	(1904)	74
St. Louis College of P. and S.	(1904)	63

Wyoming Report for 1904.—Dr. George P. Johnstone, secretary of the State Board of Medical Examiners of Wyoming, reports that during 1904 sixty-five persons were licensed to practice medicine and that seven persons were refused license because they were unable to furnish satisfactory credentials.

Rush Medical College had 11 representatives; Jefferson Medical College, 2; Eclectic Medical Institute, Cincinnati, 1; Kansas Medical College, 1; University of Colorado, 3; Barnes Medical College, 2; University of State of New York, 1; College of P. and S., Keokuk, 1; Bennett Medical College, 1; Lincoln Medical College, 2; McGill University, 1; Dalhousie University, Nova Scotia, 1; Denver and Gross Medical College, 4; Marion-Sims-Beaumont, 1; Washington University, Medical Department, St, Louis, 1; College of P. and S., Chicago, 3; Trinity College, Toronto, 1; Baltimore University, 4; Missouri Medical College, 1; University of Nebraska, 2; University of Japan, 1; University Medical College, Kansas City, 2; Eclectic Medical University, Kansas City, 1; Medico-Chirurgical College, Kansas City, 1; Homeopathic Medical College, Kansas City, 1; Columbia University, 1; National University, Washington, 1; College of P. and S., St. Louis, 1; University of Vermont, 1; University of Michigan, 1; Alexander University, 1; Germany, 1; Hospital College of Medicine, Louisville, 1; Hering Medical College, Chicago, 1; Baltimore Medical College, 1; University of Minnesota, 1; University of Buffalo, 1; Eclectic Medical College, Penn., 1; Omaha Medical College, 2; University of Iowa, 1; Kansas City Medical College, 1.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Feb. 11, 1905:

Winn, Robert N., and Thomason, Henry D., asst.-surgeons, ordered to report to Lieut.-Col. George H. Torney, deputy surgeon general, U. S. Army, General Hospital, Presidio of San Francisco, for examination for promotion not later than March 3, 1905.

Mathews, Geo. W., asst.-surgeon, retired as captain, to date Feb 2, 1905.

Smart, Robert, asst.-surgeon, order changing station from Fort Du Pont, Del., to Fort Sheridan, Ill., is revoked.

Jean, Geo. W., asst.-surgeon, granted two months' leave of absence.

Banister, Wm. B., surgeon, ordered to accompany Second Squadron, Eighth Cavalry, from Jefferson Barracks, Mo., to San Francisco, and then return to proper station.

Thornburgh, R. M., asst.-surgeon, left Fort Warren, Mass., on ten days' leave of absence.

Baker, David, and Buck, Carroll D., asst.-surgeons, ordered to accompany Sixth Infantry from Fort Leavenworth, Kan., to San Francisco.

Torney, George H., deputy surgeon general, reports in temporary charge of C. S. O. Department of California.

Smart, Robert, asst.-surgeon, ordered to proceed from Fort Du Pont, Del., to Fort Myer, Va., for duty.

Wilson, James S., asst.-surgeon, ordered to proceed from Fort Myer, Va., to Fort Oglethorpe, Ga., for duty.

Little, Wm. L., asst.-surgeon, ordered to proceed from Fort Oglethorpe, Ga., to Jackson Barracks, La., for duty.

Marvin, Marion F., contract surgeon, granted an extension of one month to his leave of absence.

Sanford, Joseph L., contract surgeon, ordered from Clinton, Va., to Fort Leavenworth, Kan., to accompany the Sixth Infantry thence to Philippine service.

Anderson, Everett, A., contract surgeon, ordered from Georgetown, Ky., to Fort Leavenworth, Kan., to accompany the Sixth Infantry thence to Philippine service.

Hewitt, John M., contract surgeon, ordered from Kewanee, Ill., to Jefferson Barracks, Mo., to accompany the Second Squadron, Eighth Cavalry, thence to Philippine service.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Feb. 11, 1905:

Wells, H., medical director, commissioned medical director, with rank of captain, from Jan. 1, 1905.

Drake, N. H., medical inspector, commissioned medical inspector, with rank of commander, from Jan. 1, 1905.

Stepp, J., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from June 7, 1904.

Bishop, L. W., asst.-surgeon, detached from the Naval Hospital, New York, and ordered to continue duties at the Navy Yard, N. Y.

Blue, J. H., and Foster, T. G., asst.-surgeons, appointed asst.-surgeons, with rank of lieutenant (J. G.), from Jan. 16, 1905.

Harmon, G. E. H., medical director, commissioned medical director, with rank of captain, from Dec. 15, 1904.

Hibbett, C. H., medical inspector, commissioned medical inspector, with rank of commander, from Dec. 15, 1904.

Guest, M. S., surgeon, commissioned surgeon, with rank of lieutenant commander, from Jan. 20, 1903.

Mayers, G. M., asst.-surgeon, ordered to the Naval Hospital, New York.

Elmore, B., A. A. surgeon, ordered to the Navy Yard, Washington, D. C., for duty at the Naval Hospital.

Von Wedekind, L. L., surgeon, ordered to the Naval Training Station, Newport, R. I., with additional duty on board the *Constellation*.

Barber, G. H., surgeon, detached from the Naval Training Station, Newport, R. I., and ordered to the *Ohio* Feb. 25, 1905.

High, W. E. G., asst.-surgeon, detached from duty with Marine detachment, Midway Island, and ordered to the Naval Training Station, San Francisco.

Tyree, F. W., A. A. surgeon, detached from the Navy Yard, Charleston, S. C., ordered to duty with Marine detachment on Midway Island.

Grunwell, A. G., surgeon, when discharged from treatment at the Naval Hospital, New York, ordered to duty at that hospital.

Odell, H. E., P. A. surgeon, detached from the Naval Hospital, New York, February 15, and ordered to the *Galveston* Feb. 15, 1905.

DeValin, C. M., surgeon, commissioned surgeon, with rank of lieutenant commander, from Jan., 31, 1903.

Plummer, R. W., P. A. surgeon, ordered to the Navy Yard, Charleston, S. C., February 17.

Public Health and Marine-Hospital Service.

List of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Feb. 5, 1905:

Gassaway, J. M., surgeon, granted leave of absence for ten days from February 9.

Richardson, T. F., P. A. surgeon, to proceed to Savannah Quarantine and assume temporary charge of the Service during the absence, on leave, of A. A. Surgeon W. J. Linley.

Wilson, R. L., P. A. surgeon, granted leave of absence for one month from March 1.

Francis, Edward, asst.-surgeon, granted leave of absence for seven days from Feb. 2, 1905, under Paragraph 191 of the Regulations. Granted extension of leave of absence for twenty-three days from February 9.

Duffy, F., A. A. surgeon, granted leave of absence for seven days from February 8.

Hargis, J. W., A. A. surgeon, granted leave of absence for twenty days from February 8.

Linley, W. J., A. A. surgeon, granted leave of absence for thirty days from February 13.

McConnell, E. F., A. A. surgeon, granted leave of absence for thirty days from February 1.

Morris, G. A., pharmacist, relieved from duty at Fort Stanton, N. M., and directed to proceed to St. Louis, Mo., and report to the medical officer in command for duty and assignment to quarters, relieving Pharmacist J. M. Bell.

Bell, J. M., pharmacist, on being relieved from duty at St. Louis by Pharmacist G. A. Morris, to proceed to Fort Stanton, N. M., and report to the medical officer in command for duty and assignment to quarters.

BOARD CONVENED.

Board convened to meet at the Marine Hospital, Baltimore, Feb. 3, 1905, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon C. W. Wille, chairman; A. A. Surgeon G. H. Steuart, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from Feb. 3 to Feb. 11, 1905:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, Jan. 28-Feb. 4, 1 case.

Georgia: Macon, Jan. 21-28, 1 death.

Illinois: Jan. 28-Feb. 4, Chicago, 13 cases, 6 deaths; Galesburg, 1 case.

Kansas: Topeka, Jan. 28-Feb. 4, 1 case.

Louisiana: New Orleans, Jan. 21-Feb. 4, 23 cases, 1 death, 9 cases imported.

Maine: Perry, Feb. 1, 1 case.

Michigan: Detroit, Jan. 28-Feb. 4, 3 cases.

Missouri: St. Louis, Jan. 28-Feb. 4, 38 cases.

New York: New York City: Jan. 21-Feb. 4, 9 cases, 1 death.

Ohio: Toledo, Jan. 28-Feb. 4, 6 cases.

South Carolina: Charleston, Jan. 28-Feb. 4, 5 cases.

Tennessee: Jan. 28-Feb. 4, Memphis, 14 cases; Nashville, 8 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Dec. 10-24, 2 cases.

SMALLPOX—FOREIGN.

Bosnia and Herzegovina, Nov. 1-30, 22 cases, 3 deaths.

Brazil: Pernambuco, Dec. 15-31, 110 deaths; Rio de Janeiro, Jan. 1-8, 45 cases, 15 deaths.

Ecuador: Guayaquil, Jan. 4-18, 3 cases; Manabi Province, Jan. 4, present.

France: Paris, Jan. 14-21, 17 cases, 3 deaths.

Germany: Bremen, Jan. 7-14, 1 case.

Great Britain: Glasgow, Jan. 20-27, 1 death; Jan. 14-21, Hull, 4 cases; Liverpool, 1 case; London, 1 case; Newcastle-on-Tyne, 11 cases; South Shields, 11 cases.

India: Bombay, Dec. 20-Jan. 10, 102 deaths; Calcutta, Dec. 17-Jan. 7, 5 deaths; Karachi, Dec. 24-Jan. 8, 6 cases, 1 death; Madras, Dec. 17-Jan. 6, 5 deaths.

Italy: Catania, Jan. 12-26, 4 deaths; Palermo, Jan. 7-21, 43 cases, 9 deaths.

Luxemburg: Dec. 1-15, 3 cases.

Mexico: City of Mexico, Dec. 17-Jan. 7, 4 cases, 4 deaths.

Netherlands: Rotterdam, Jan. 21-28, 2 cases.

Russia: Jan. 7-14, Odessa, 1 case; St. Petersburg, 2 cases, 3 deaths; Warsaw, Nov. 26-Dec. 3, 3 deaths.

Spain: Barcelona, Jan. 10-20, 12 deaths.

Straits Settlements: Singapore, Dec. 17-31, 2 deaths.

Turkey: Constantinople, Jan. 15-22, 17 deaths.

Venezuela: La Guaira, Jan. 21, epidemic.

YELLOW FEVER.

Brazil: Rio de Janeiro, Jan. 1 8, 1 case.

Mexico: Coatzacoalcos, Jan. 21-28, 1 case; Merida, Jan. 22-28, 1 case.

Panama: Colon, Jan. 28, 1 case, probably imported.

PLAGUE—INSULAR.

Philippine Islands, Manila, Dec. 3, 1 death.

PLAGUE—FOREIGN.

Africa: Cape Colony (East London), Dec. 25, 1 death.

Arabia: Aden, Dec. 31-Jan. 14, 161 cases, 116 deaths.

Brazil: Guaratingueta, Nov. 30-Dec. 18, 11 cases; Rio de Janeiro, Jan. 1-8. 22 cases, 11 deaths.

Egypt: Dec. 31-Jan. 7, Suez, 2 cases, 3 deaths; Tukh, 1 case, 1 death.

India: Bombay, Dec. 20-Jan. 10, 374 deaths; Calcutta, Dec. 15 Jan. 7, 67 deaths; Karachi, Dec. 25-Jan. 8, 120 cases, 105 deaths.

Siam: Bangkok, Dec. 17-24, present.

Siberia: Slobodskoi and Vigatka districts, Oct. 18-Dec. 14, 227 cases.

CHOLERA.

India: Bombay, Dec' 20-Jan. 10, 1 death; Calcutta, Dec. 15-Jan. 7, 304 deaths.

Russia: Dec. 7-14, Astrachan, 1 case; Baku province and city, 459 cases, 355 deaths; Erivan province and City, 1,506 cases, 1,265 deaths; Samara, 17 cases; Saratov, 10 cases; Trans-Caspian province, 40 cases, 1 death.

Turkey in Asia: Jan.-Dec. 26, 10,466 cases, 9,192 deaths.

Medical Organization.

Delaware.

This state now has a medical society in each county, every one of which has adopted the standard constitution and by-laws.

Sussex County Medical Society.—This society has elected Dr. Robert B. Hopkins, Milton, president, and Dr. Roland G. Paynter, Georgetown, secretary.

Kent County Medical Society.—At the annual meeting, Dr. James H. Wilson was elected president, and Dr. L. August H. Bishop, secretary, both of Dover.

Newcastle County Medical Society.—At the annual meeting, Dr. Peter W. Tomlinson was elected president; Dr. Joseph P. Wales, vice-president; Dr. Harold L. Springer, secretary, and Dr. William G. Winner, treasurer, all of Wilmington. The society endorsed any and all measures looking toward establishing a high standard of purity of the milk supply. At a previous meeting the standard constitution and by-laws had been adopted.

Nevada.

Nevada State Medical Society.—At the annual meeting of the Nevada State Medical Society, held in Reno, Dec. 19, 1904, the society was reorganized on the standard plan with the following officers: Dr. W. Lee Moore, Verdi, president; Drs. Charles E. Mooser, Reno, and M. R. Walker, Reno, vice-presidents, and Dr. John L. Robinson, Reno, secretary-treasurer.

South Carolina.

Georgetown County Medical Society.—Physicians of the county met at Georgetown, February 6, and after addresses by Dr. Walter Cheyne, councilor of the district, and Dr. J. N. McCormack, organized a county society on the standard plan, with the following officers: Dr. M. P. Moorer, president; Dr. H. D. Beckman, vice-president; Dr. Olin Sawyer, secretary-treasurer; Drs. F. C. Clark, W. M. Gaillard and L. B. Salters, censors, and Dr. William E. Sparkman, delegate to the state association, all of Georgetown.

Greenwood County Medical Society.—Dr. J. N. McCormack addressed a meeting of physicians of the county at Greenwood, February 10, after which a county society was organized on the standard plan with the following officers: Dr. G. Pressly Neal, Greenwood, president; Dr. John Lyon, Ninety-six, vice-president; Dr. R. B. Epting, Greenwood, secretary; Drs. James B. Hughey, Greenwood, William T. Jones, Jones, and F. G. Moss, Verdery, censors, and Dr. Sanders L. Swygert, Greenwood, delegate to the state medical association. Dr. Mayer, councilor of the district, was unable to be present owing to serious illness.

Society Proceedings.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Jan. 11, 1905.

The First Vice-President, Dr. Franklin B. Stahl, in the Chair.

The Practice of Medicine in India.

Dr. Anna M. Fullerton gave an account of the difficulties attending the practice of medicine in India in consequence of social and religious customs. This, with the dense ignorance and grinding poverty of the mass of the people, are responsible for the widespread epidemics which prevail and which have baffled all the efforts of the English government to suppress. High caste women can never see a male physician, but must be treated by ignorant native midwives, and shocking mutilations often occur, for which repair of any kind is impossible. The hospitals established by the English government, and especially mission hospitals and dispensaries, are creating a sentiment in favor of western medicine.

The Antitoxin Treatment of Diphtheria.

Dr. B. Franklin Royer of the Municipal Hospital, by statistics of the Board of Health of Chicago, New York City, Brooklyn and Philadelphia, proved an actual decrease in the loss of life in each city respectively at 5,400, 8,204, 951, and 1,853, a total for these four cities, without allowing for increased population, of 16,408 lives. By a table including 67,748 patients treated in the Metropolitan Asylums Board Hospital, a decrease in death rate of 15.24 per cent. was shown. By a table from the South Department in Boston, reporting 16,544 cases, a decrease of 29.26 per cent. was shown. In the Municipal Hospital, reporting 10,219 cases, there was a decrease of 10 per cent. He recommended that the dose of antitoxin be in proportion to the amount and location of exudate. He recommended large doses of antitoxin in nasal, naso-pharyngeal and laryngeal diphtheria, and urged a more general use of antitoxin as an immunizing agent, and earlier in the disease, without waiting for culture returns. The dose in use at the Municipal Hospital is: for tonsillar exudate (single), 2,500 units; purely tonsillar (double), 5,000 units; tonsillar exudate with pillars and uvula or pharynx involved, 7,500 to 10,000 units: nasal and any other part involved or for laryngeal diphtheria, 7,500 to 10,000 units. Repeat the dose in each type of disease in from 12 to 24 hours, depending on the sign of improvement, and every 24 hours thereafter; when a large amount of exudate persists, a dose of 5,000 to 7,500 units is given until a good part of the exudate has disappeared

Severe Case of Acute Chorea Treated Successfully with Apomorphin.

Dr. Montrose Graham Tull reported a case of acute chorea coming on gradually in a girl, fifteen years of age, with menstruation not fully established, presenting symptoms of acute mania, thickened tongue, gutteral and unintelligible articulation and with incessant choreic movements. The body was covered with a confluent, morbilliform rash. After all the accepted forms of treatment had been tried with absolutely no effect, he concluded to try apomorphin in tentative doses: one fortieth of a grain was administered hypodermically with remarkable result. The choreic movements ceased in about three minutes, and the child slept peacefully and quietly. One twentieth of a grain of apomorphin, every three hours, by the mouth, was continued for three or four days, in addition to the arsenic which she had taken from the beginning, and the patient made an uninterrupted recovery.

Regular Meeting, held Jan. 25, 1905.

The President, Dr. James M. Anders, in the Chair.

The Need of Early Operation in Surgical Diseases of th

Abdomen.

Dr. John B. Roberts exhibited a specimen of stricture of the sigmoid flexure due to ulceration of the mucous memb the A diagnosis of obstruction of the gastrointestinal canal in th neighborhood of the pylorus and duodenum had been The condition of the patient was so bad that a jejun was performed for the purpose of feeding the patient a more extensive examination of the abdomen. Death after a few days from exhaustion. It was then found that obstruction was in the sigmoid flexure. Early operative would almost certainly have been accomplished by excision of the gut or by intestinal anastomosis. The second specimen showed a perforated duodenal ulcer close to the pylorus. A time for operation was appointed, but before that time perforation occurred. Immediate operation was then advised as a last resort, but the patient and his friends would not consent. Dr. Roberts believed that a gastrojejunostomy, done a day or two prior to the time of perforation, would have saved this patient's life. Specimen No. 3 was a perforated appendix removed from a case which had come under Dr. Roberts' care about forty hours after an attack of abdominal pain. When he saw the man his pulse was 160 and very feeble. His hands were cold; his face was covered with a clammy sweat, and the abdomen was distended and painful. Believing that operation would almost certainly result in death, Dr. Roberts abstained from even opening the abdomen. Autopsy showed the lower abdomen full of pus, with a gangrenous opening in the appendix big enough to admit a lead pencil. The fourth specimen was a large gallstone, measuring an inch and a half by three-quarters of an inch, from the gall bladder of a woman who for a number of years had suffered repeated attacks of pain in the region of the gall bladder. Operation showed the stomach, gall bladder, liver and omentum to be bound together by old and firm adhesions. The gall bladder was dragged backward until its fundus pointed toward the spinal column. It was entirely filled by this large stone. The patient had, in addition, a bent and adherent appendix from former attacks of appendicitis. The gall bladder was opened, the calculus removed, and the appendix excised. Drainage through the lumbar region was employed and a large drainage tube was introduced through the abdominal incision. The patient did moderately well for about two days and then died from asthenia. The case illustrated the importance of cholecystotomy in the early stage of all cases of gallstone disease. The fifth specimen was a globular gallstone, about three-quarters of an inch in diameter, removed from the junction of the hepatic, cystic and common gall ducts. The patient had great pain, and persistent jaundice, which at the time of operation gave her a dark bronze color. Choledochotomy was required for extraction of the stone and was followed by hepatic and abdominal drainage. The specimens were shown to call attention to the importance of operating on gall-bladder disease, inflammations of the appendix, and obscure lesions of the stomach and intestines early. Dr. Roberts believes that the best results will undoubtedly be obtained in such cases by early exploratory incision, followed by operations for relief, even if such surgical methods are employed before definite diagnosis can be made. He stated that the profession and the public should realize that this is the teaching of modern surgery.

A New Saw for Cranial Surgery.

DR. H. C. MASLAND exhibited a skull saw, which will be illustrated in THE JOURNAL.

DISCUSSION.

DR. JOHN B. ROBERTS said the saw seemed to be a very efficient instrument, and agreed with Dr. Masland that it did not need the guard, since in cutting through bone one can tell by the feeling when it is cut through.

DR. T. H. WEISENBURG did not agree with Dr. Masland that it was not necessary to have the saw set to cut thicker than a quarter of an inch, since he had seen some skulls in which a deeper cut was required. Neither did he agree that it was unnecessary to have a circular incision. The circular flap, in his opinion, is more easily replaced and is better for cosmetic reasons. He further disagreed with Dr. Masland in regard to the matter of time, and referred to Dr. Frazier's operations in the University Hospital, in which he opened the skull in two minutes and seldom exceeded three or four minutes, which Dr. Weisenburg thought could scarcely be improved on.

DR. MASLAND said that the instrument used by Dr. Frazier made an incision an eighth of an inch wide, which does not offer so great a probability of union through the line of incision as a cut one millimeter in width. This also guarantees a minimum waste of bone, and replacement without sinking.

The Limitations and Possibilities of Electricity in the Treatment of Diseases of Women.

DR. BARTON COOKE HIRST has found an advantage in the use of galvanism and faradism in a limited number of diseases of women. As a hemostatic agent, in uncomplicated small fibroid tumors, with no other symptoms than metrorrhagia, it is one of the most efficient. He finds electricity useful also in the treatment of amenorrhea and sterility the result of imperfect development, or atrophy of the uterus. Two illustrative cases were reported in which normal menstruation was restored and conception occurred, following this treatment. In one woman there had been amenorrhea for a year. In the other the menstruation had been reduced to a scanty discharge, lasting less than a day, the result of lactation atrophy. The third indication is to restore tone to a paretic sphincter ani muscle after its restoration by surgical means, in cases in which repeated attempts had been made to restore the muscle, with failure, and in which there had been no contractile power exercised for a number of years. A fourth indication for the use of electric currents was found in certain types of dysmenorrhea associated with a poorly-developed uterus. Local treatment, however, he believes, is very rarely practicable in such cases. This comprises all the conditions in which it can be hoped to accomplish much by electricity.

Toxic Changes in Brain and Spinal Cord Due to Carcinoma.

DR. T. H. WEISENBURG said that the influence of carcinoma of parts other than the brain and spinal cord on the nervous system is becoming better recognized. Metastasis may occur in the brain, where it may be either in the form of a tumor or as an infiltration of cancer cells of the pia of the cortex or of the base of the brain. A case is recorded where basal syphilis was diagnosed, but at the autopsy a metastatic cancer was found. This teaches that whenever cerebral symptoms occur in the course of carcinoma, no matter in what form they appear, metastasis should be thought of in the diagnosis. In the spinal cord, metastasis generally involves the spinal vertebræ, causing a pressure myelitis. Cases are recorded where during the course of the disease such symptoms as mental apathy, dementia, hemiplegia and aphasia occurred. These are undoubtedly of toxic origin. Dr. Weisenburg stated that he has recorded cases of bulbar symptoms and dementia in which a careful microscopic examination of the brain and spinal cord demonstrated alterations in the nerve cells of the medulla oblongata and pons. In another case, where there were no cerebral symptoms, changes were also found in the nerve cells of the cortex. Such findings have not been previously recorded.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Jan. 25, 1905.

The President, Dr. John B. Murphy, in the Chair.

The Therapeutic Use of the X-Rays.

DR. WILLIAM ALLEN PUSEY read a paper with this title which will appear in THE JOURNAL.

The Treatment of Lymphatic Leukemia with the X-Ray.

DR. JOSEPH A. CAPPS and DR. JOSEPH F. SMITH reviewed the progress made in this field.

The first case was treated by Dr. Pusey for one month, but without improvement. In 1903 Dr. Nicholas Senn reported a case of leukemia symptomatically cured. The patient presented the typical symptoms of splenomyelogenous leukemia, and had been ill for fourteen months. Treatment was begun daily and was given every other day, through the latter part of January, and during February, March, April and May, and at the time of Senn's last observation, the white count came down to 10,000, and the spleen was almost of normal size. The patient felt perfectly well, but died later with symptoms of toxemia. Cases of lymphatic leukemia treated by Senn, Churchill and Pusey died inside of seventeen months.

The authors reported three cases of lymphatic leukemia treated by the x-rays, two of which were of the acute form. One patient died in six days, and the other in ten days. Of the subacute cases there were two. While the *x*-ray exerted a beneficial effect, it did not control the disease. Better results were obtained in treating the chronic cases, and of these the authors reported three instances. They stated that patients with splenomyelogenous leukemia should receive *x*-ray treatment because they are greatly benefited thereby. They respond more slowly than do patients with chronic lymphatic leukemia. These patients feel that they are cured, but in the light of Senn's case and of other cases reported as symptomatically cured, some of which have since died, physicians must not be too sanguine in regard to pronouncing cures. It is altogether probable that some of these cases are not cured, but that the process is held in abeyance. Oftentimes in leukemia the spleen will diminish in size and the blood count come down under *x*-ray treatment, and the patient, so far as the leukemia is concerned, is very much better symptomatically, but the disease reasserts itself always.

DISCUSSION.

Dr. Oliver S. Ormsby referred to observations of more than two hundred cases of epithelioma treated by the *x*-ray. The cases that had been relieved most were of the superficial rodent ulcer type. The results were uniformly good. In two cases there was a mild recurrence. Nineteen cases of superficial epithelioma of the lip were treated with excellent results. Psoriasis of the scalp can be removed with the *x*-ray without removing the hair. The results in eczema and in acne rosacea are excellent. In seventeen cases of sycosis the results were good, one-half of the patients being entirely well. In two obstinate recurrences took place. In keloid their results in eleven cases were the same as those mentioned by Dr. Pusey. Thirty-five cases of lupus erythematosus were treated, combining radial with phototherapy, with excellent results.

Dr. E. A. Fischkin stated that cases of sycosis and keloid reacted beautifully to *x*-ray treatment. He spoke of the idiosyncrasy of different patients to the *x*-ray. He mentioned two patients who had psoriasis, a brother and a sister; the sister was cured after six or eight treatments, with no recurrence after two years. Although the brother has had over one hundred treatments, the psoriasis has increased all over the body. There is no evidence of cure of any of the lesions. This case illustrates that there is a decided difference in the reaction of patients to the *x*-ray.

Dr. R. R. Campbell stated that in two cases of blastomycosis which he had treated by the *x*-ray without the administration of iodid of potassium his results had been the same as those of Dr. Pusey. The cases of epithelioma of the lip he had selected for *x*-ray treatment were of the superficial type. In two cases out of twelve, in which there was some slight induration, he failed to get any beneficial results from the *x*-ray. In a case of epithelioma of the lip, in which it becomes necessary to curette, he thinks the domain of the *x*-ray ceases, and the case properly belongs to surgery. His results in lupus erythematosus have not been satisfactory. In lupus vulgaris the *x*-ray is eminently the best treatment. In acne his experience has been gratifying.

Dr. David Lieberthal corroborated what the other speakers said in regard to the treatment of acne, lupus vulgaris, acne rosacea, etc., with the *x*-ray. He emphasized the importance of carefully selecting and classifying cases.

Administration of Oxygen Gas.

Dr. H. J. Burwash referred to a paper by Kellogg of Battle Creek, Mich., entitled "Oxygen Gas Per Enema," which was published in 1887. In this paper, Kellogg discusses at length experiments on guinea-pigs, showing that this gas per enemata is readily absorbed, and that dark venous blood is noticed to be immediately changed into bright arterial blood by its application. He, therefore, recommends this method for the treatment of diseases of the liver and digestive organs. He reports many cases, nearly all being of digestive troubles. Dr. Burwash has made a new application of this method by using it in the treatment of the acute respiratory diseases, particularly pneumonia. He first used it in August, 1891, in a severe typhoid case, after failing to resuscitate the patient by the usual method of inhalation. The patient was a young girl, sixteen years of age, who became profoundly toxic, delirious and cyanotic. The gas by inhalation did not appear to revive her from the stupor, and then it occurred to him to administer the gas per enema. He gave her one gallon; after two minutes' duration the respiration became more exhilarated, and the deep cyanosis disappeared. The patient recovered after a very protracted illness.

Since that time he has continued to use oxygen per enema in all his critical cases, especially pneumonia. It is plainly apparent that the introduction of a large quantity of oxygen into the intestinal canal not only neutralizes and deodorizes the noxious gases that are frequently present there, but also introduces oxygen through the portal system to the liver, whose cells are not only stimulated to greater activity, but are nourished as well. Besides this, the already overcharged lungs are assisted in their function of aëration of the blood.

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, held Dec. 9, 1904.

Dr. Samuel Wolfe in the Chair.

Report of a Case of Pancreatic Cyst.

Dr. M. J. Karpeles reported the case of a male, aged 68, with a negative family and personal history. He first complained of discomfiture in the left side, the principal symptoms being marked nausea, with occasional vomiting of a dark green, non-odorous, thin watery fluid, in an amount out of proportion to that ingested; general pruritus, especially of the hands; dyspnea on least exertion; profound weakness; epistaxis; colicky pains, and frequent attacks of diarrhea and insomnia. The stools were found to be free from fat. The urine showed a low specific gravity, a trace of albumin and the presence of bile. On physical examination a tender area was elicited at the costal margin in the left mammillary line. Ten days later, it was possible to outline in this region a mass the size of an egg which, at the time of the patient's death, about three weeks later, involved the left half of the epigastrium, the left hypochondrium, the umbilical and the left lumbar regions. As this fluctuating mass, which was diagnosed as a pancreatic cyst, enlarged, the gastrointestinal symptoms proved more rebellious, the jaundice became more marked, the insomnia required hypnotics, and the general discomfiture increased. In view of the marked prostration and jaundice, operation was not deemed advisable. At autopsy a large pancreatic cyst was found, containing about two liters of a grayish fluid. The cyst wall was thin and the inner lining smooth. It was impossible to determine the part of the gland in which the cyst originated.

DISCUSSION.

Dr. David Riesman stated that in the differential diagnosis we should consider (1) cystic gall bladder; (2) hydronephrosis; (3) echinococcus cyst in women, and (4) ovarian cyst. He stated that jaundice is not so prominent in cases of cystic gall bladder, but may be present. In hydronephrosis with renal crises and long history of pain, floating kidney should be taken into consideration; ovarian cyst should be differentiated by vaginal examination, and echinococcus cyst by the patient's habits. In the case reported, exhaustion and epistaxis rendered operation inadvisable, although possibly tapping of the sac, after sewing or stitching it to the abdominal wall, might have been of value, if the epistaxis had not been so great. Where the tumor occurs in the epigastrium, extending into the left hypochondrium, and is accompanied by pains in the celiac plexus, these symptoms are sufficient to warrant a provisional diagnosis of pancreatic cyst. The danger of fat necrosis occurring by reason of the fluid getting into the abdominal cavity is quite small, although cases have occurred in which the tumor evacuated itself into the intestinal canal. The surgical treatment is the one that should be employed.

The Etiology and Diagnosis of Cholelithiasis.

DR. WILLIAM RUOFF stated that no common etiologic factor could be assigned to all cases. Age is an important factor, the majority of cases occurring between the ages of 40 and 60, and the more frequent occurrences in females he laid to the mode of dress and pregnancy. The influence of age might be manifested through the loss of contractile power of the bladder, thus favoring retention and the lack of resisting power of the body fluids. He felt that too much importance is attached to temperament, gluttony, excessive indulgence in meats and fats, heredity and climate. He discussed in detail the different varieties: (1) Pure cholesterin stone; (2) laminated cholesterin stone; (3) ordinary gallstones; (4) mixed bilirubin-calcium stones; (5) the rarer forms, such as (a) amorphous stones, resembling pearls: (b) chalk stones; (c) concretions surrounding foreign bodies; (d) casts of bile ducts. He then considered in detail the infective causes through the medium of the portal circulation and through an ascending infection from the common duct, and the influence of appendicitis, salpingitis, peritonitis, etc. The diagnosis was considered under three heads: (1) cases in which no symptoms have been produced and which are usually discovered at autopsy; (2) transitory symptoms of dyspepsia and abdominal and liver symptoms; (3) those cases causing severe and, at times, almost fatal illness, which are most frequently met with. The symptoms of jaundice, vomiting, hepatic and cystic infection were considered, as was also the symptom of impaction.

Gallstone Disease, Remote Effects and Treatment.

DR. SAMUEL P. GERHARD stated that our efforts must be mainly surgical; that the gallstones, as long as they remained in the bladder, are perfectly harmless, but that the danger is due to the liability of accidents in their passage through the common duct, considering under this head cholecystitis, empyema and gangrene, pancreatitis, fistula into a neighboring organ, peritonitis, etc. The medical treatment should be prophylactic, directed to preventing rather than curing the disease.

DISCUSSION.

DR. DAVID RIESMAN stated that the youngest patient he had ever seen was 11 years, and the oldest 70 years. He said that the essential features in the diagnosis are pain in the region of the gall bladder below the costal cartilage in the right parasternal line, although the location of the pain is not absolutely necessary, and vomiting and jaundice. He referred to the case of a man, 37 years of age, who had suffered from cramplike pains for a number of months, chiefly in the epigastric and left hypochondriac regions, unassociated with vomiting. He had lost 20 pounds in weight. At operation, gallstones were found in the cystic duct; there was no jaundice and no tenderness in the gall bladder region. He also referred to several other cases in which the characteristic symptoms were not present. In his experience the *x*-ray has not been of value in the diagnosis of these cases. He referred to the method of Dr. DaCosta of placing a cylindrical pad under the patient, so that the patient forms an inclined plane with the table, and then by gently rubbing with the hand, an enlarged gall bladder may be felt. Referring to the pathogenesis, he stated that, without infection, the passage of the stone would cause inflammation of the gall bladder and ducts. He believes that many of the cases which were called biliousness were really due to gallstone attacks. He referred to the occurrence of the condition after infectious diseases, and referred to a case diagnosed as duodenal ulcer, which on operation proved to be an infected gall bladder. The persistence of jaundice should suggest a stone or malignant disease. He expressed the belief that the surgical treatment would assume the same place it had in appendicitis.

DR. JOHN B. DEAVER stated that he had never seen nor operated on a case of gallstones in a colored subject. He divided the condition into two classes: cholelithiasis of the gall bladder and affections of the common duct. The pain and tenderness in the epigastrium are less frequent in disease of the common duct than in gall-bladder inflammation. He believes that the pain in the majority of instances is due to infection. Jaundice as a diagnostic factor is very misleading. He never operated on acute cases, but if the symptoms persist, then the value of operation must be considered. The *x*-ray is not of much value in diagnosis. He did not recommend operation in cases of acute common duct obstruction. The operation, if performed, should be done early. He does not approve of operating in private houses. He emphasized the value of careful preparation of the patient prior to operation, including careful urinalysis. Stomach analysis is not of much value, except in cases of acute leucocytosis. He favored drainage of the gall bladder rather than its removal, unless there was some indication for the latter procedure.

DR. WILMER KRUSEN referred to the case of a woman, 32 years of age, who had suffered with gall-bladder disease for a period of eight years without the true condition being suspected. The *x*-ray failed to reveal the seat of the trouble. At the operation for removal of a cystic ovary, forty-three stones were removed from the gall bladder and the woman made a good recovery. Another case was reported, in which an operation was done for appendicitis and the appendix was found not to be diseased. Two days later the patient had a pulse of 140, temperature of 103 to 104, and a marked enlargement over the gall bladder. Operation showed an empyema of the gall bladder, and 420 stones were removed therefrom, but the patient died within twenty-four hours from general peritonitis. He believes that gall-bladder disease is as much a surgical procedure as appendicitis, and that the sooner the operation is done the better for the patient.

Travel Notes.

AN INTERSEMESTRAL EXCURSION.

LEWELLYS F. BARKER, M.D.

CHICAGO.

(Continued from page 497.)

Vienna.

One of the first questions a medical traveler is likely to be asked by his colleagues on his return to America is: "How did you like *Vienna?*" And a layman hearing that a physician has spent some months in Europe almost invariably remarks, "I presume that you spent most of your time in Vienna," such a fame has that city had as a medical center. Although in Europe twice before, on neither trip had I been able to visit the Austrian capital; I was all the more anxious, therefore, this time to arrange to visit the city and its hospitals and to meet some of its famous medical men.

UNIVERSITY OF VIENNA.

The University of Vienna, founded as long ago as 1365, compels on account of its remarkable history the veneration and respect of every visitor. And in that history the medical faculty has played a very important part, not only in the development of medical teaching and practice, but also in the forwarding of the interests of science and arts in general. One has only to read that best of books on medical education, Billroth's "Ueber Lehren und Lernen," to become impressed with the influence of the medical faculty on the progress and development of the University of Vienna as a whole. Great organizing minds like that of the distinguished Van Swieten are rare, even in the greatest of universities; fortunate are those institutions within which they occasionally develop. One such man may shape the destiny of a university for generations; this has been true in Vienna, and it is pleasing to find that the Viennese, conscious of their debt to a great master, have in more than one artistic movement done their best to perpetuate the memory of Van Swieten in the city he loved and for which he worked.

VIENNA AS A MEDICAL CENTER.

While Vienna has long enjoyed the reputation o[illegible]ing the most important medical center in [illegible]ope, and i[illegible] doubtless very great, there are some who think that it can no longer justly lay claim to the first place. That honor, they think, now belongs to Berlin. The latter city has in the last ten years made enormous strides forward; one would scarcely believe the change without actually observing it for himself; Vienna seems—some have even dared to say—a little provincial by comparison. The explanation in all probability lies in the growing prosperity of Germany, the increase in material means in the capital of the German empire, the determination to seek the best men for university chairs irrespective of their nationality, and the encouragement of original research in the various departments rather than directing too much effort toward increasing the number of under graduate students and of the less advanced class of postgraduate workers. Vienna, it is asserted, is not as prosperous a city now as Berlin, the finances of Austria are not in as satisfactory a condition as those of Germany, the money available for university purposes is less,[2] there has been, these critics hold, a tendency to "in-breeding" in the faculty, the average Austrian and especially the average Viennese is no lover of travel, is prone to be satisfied with "good old Vienna," and to know but little and care less of what goes on in the world outside it; finally, it is maintained that, with notable exceptions, of course, the efforts of the faculty have been devoted too exclusively toward teaching the known and too little toward the discovery of the hitherto unknown. But even if these critics are right, it should be remembered that it is difficult to make a statement which is just in general without appearing to be unjust in particular. There are undoubtedly in Vienna to-day a number of the most energetic and productive scientific investigators that exist in the world, widely-traveled men of broad training, men with the highest ideals and with great capacity for work who are demonstrating constantly their right to positions in the front rank of medical research.

The material for clinical, anatomic and pathologic work in Vienna is superabundant; its concentration in and about the huge *Allgemeine Krankenhaus* has made medical work there very convenient for the student. Recently a more centrifugal tendency has been noticeable; the work at the Rudolf Spital, the Kaiser Franz-Josef Spital and the Kk. Wilhelminer Spital is rapidly increasing in importance.

Anatomy and histology are well taught in Vienna in the two anatomic institutes, one under the direction of Prof. Carl Toldt, the founder of modern conceptions concerning the development of the alimentary tract and the peritoneal cavity, and the author of the magnificent anatomic atlas which bears his name, the other under the leadership of Prof. Emil Zuckerkandl, well known through his book on topographic anatomy and his original researches on the comparative anatomy of the brain. Dalla Rosa, Tandler and Grosser are active members of the staff. The histologic courses are ably conducted by Professor von Ebner and his assistants, Schaffer and A. Rabl. The anatomic museum is rich in beautiful preparations; the amusing skeleton groups designed and erected by Hyrtl, are among the curiosities to be seen there.

Toldt's atlas, like Spalteholz' Atlas of Human Anatomy, is a triumph of modern bookmaking art; these two works have gone far and will go farther toward making anatomic ideas more exact than ever before and toward unifying and simplifying anatomic nomenclature. The illustrations in both atlases are excellent and are invaluable not only as an aid to dissection, but as a reference book in the practical work of the physician and surgeon. Every practitioner would find it profitable to own and use at least one of these atlases. Both Spalteholz and Toldt have already been translated into English.

Physiology (under Professor Exner's direction) is just moving into a fine new laboratory in Vienna. The new building is adjacent to the older structure: the latter is now to be given over to neurology (under Obersteiner) and to one or two other sub-departments.

It seemed to me that the best organized and most actively productive department in the medical faculty of the University of Vienna was that of pathology, with Richard Paltauf as professor of general and experimental pathology and Anton Weichselbaum as professor of pathological anatomy. Along with these two well-known investigators are associated Gustav Gaertner, Arthur Biedl, H. Albrecht, Anton Gohn, Richard Kretz, F. Schlangenhaufer, Rud. Kraus, H. Winterberg, O. Stoerk, and K. Sternberg, a list of names from which the fame of the university has really much to hope. Biedl's experimental studies on the nervous system, Kretz's investigations on the liver, and Kraus' original researches on bacteriological problems and curative serums are among the most interesting of current conduction. The accounts of their results have to be read by all who keep abreast with progress in these fields.

THE SEROTHERAPEUTIC INSTITUTE.

Professor Paltauf is also the director of the State Serotherapeutic Institute of Vienna and one of the most interesting forenoons I spent in the city was devoted to visiting it in his company. The institute is divided into two parts, one for the strictly scientific work of the institute and the business office, the other for the preparation of serum in large quantities. The former should be situated close to other scientific institutes and close to the postoffice, express office and telegraph station; the latter should be placed where room for extensive stables is available, and where the animals can be exercised in the open air. These different needs were met by establishing the scientific work of the institute and the business office for the distribution of serum temporarily in the bacteriologic institute of the "Rudolfstiftung," while the department for the preparation of serum on a large scale was instituted in the Court of the Kaiser Franz Joseph Hospital in the extreme outskirts of the city. Here stalls have been built for 50 horses, a piece of ground has been set aside for a riding ring in which the horses are saddled and ridden for a certain length of time each day for exercise, and a very complete serum-institute, occupying an area of 360 square meters, has been constructed. On the south side of the latter, an operating room 51 meters square has been built. The description of the Institute given by the resident assistant, Dr. Jellinek[3], should be helpful to any planning a similar structure.

In drawing the plans for the institute, the principle of separating as completely as possible from one another the individual departments with their laboratories for the different kinds of work was adhered to. The various staircases together with the entrance corridor occupy the middle of the building; the machine-rooms are in the cellar; on the ground floor on the left are the rooms for collecting and preparing serum, on the right the laboratories for chemical work and the small rooms used for testing and standardizing the sera. Upstairs, on the right, completely isolated from the other parts of the building, are the laboratories for bacteriologic and histologic work, with all necessary equipment; on the same floor, on the left, are two apartments for resident assistants. Each part of the building has its separate entrance from the central halls.

The institute has been fitted up with the most modern appliances in the way of thermostats, sterilizers, autoclaves, vacuum-pumps, etc. The arrangements for leading the horses in and out of the operating room and for drawing the serum have been made most convenient and simple. The blood obtained by sterile puncture of the vena jugularis is received in sterilized glass cylinders (provided with an [illegible] cover, so arranged that the jars can be filled without entrance of air), and placed in a cooling-room for two days to let the serum separate well. The serum is then transferred under aseptic precautions into large flasks and again allowed to stand for six weeks in the cool room, nothing being added to the serum as yet. By this time the serum has become quite clear; through quiet standing nearly all of the blood corpuscles and flocculi of fibrin have fallen to the bottom. The serum is then transferred to other flasks, in which it is treated with carbolic acid (0.5 per cent.), a precipitate of albumin, phosphates and cholesterin forms, and is filtered off, and the filtrate is preserved in large, flat-bottomed flasks in the cooling chamber.

---

[2] The income of the University of Berlin for the year 1903 was 3,406,914½ marks; that of the University of Vienna for 1897 was only 1.159,594 florins.

[3] Jellinek, O.: Die Abteilung für Serumgewinnung des k.k. serotherapeutischen Institutes in Wien. Wien klin. [illegible] 1903, pp. 1403-1405.

The chemical laboratory has been well-planned and though not large, has in it everything necessary for the work, including hood for gases, work tables, sets of reagents, precision-balances, water and gas, vacuum-pump connection, compressed-air connection, centrifugal machine and contact for electrical power for motors.

The bacteriologic laboratories have broad, high windows, lighted from the north: the work tables at the windows rest on iron brackets set into the wall, so that the floor-space remains entirely free; the tables are covered with white enamelled lava, a material which resists chemicals and dyes better than glass or oak, and which on account of its white color makes for cleanliness. The largest thermostat measures nine square meters and is two and one-half meters high; it is heated by gas, can be exactly regulated for any temperature between 33 and 40° C.; that it works well is shown by the curve of the self-registering thermometer attached. A special wash-room has been provided for this laboratory with its own sterilizing apparatus, in order that tubes, glass vessels and other objects used here need not be removed for cleaning to other parts of the building; this is one of the many safeguards against contamination of the laboratory in which the serum is prepared. The machinery in a sero-therapeutic institute is rather complex and a good mechanic is essential to the establishment. A four-horse power electric motor runs a small ammonia refrigerating machine, and a half-horse power motor runs a salt-water pump which pumps the concentrated solution of magnesium chlorid cooled by the machine to —10 degrees C. from the refrigerator to the tubes which cool the rooms in which the serum is kept in the parterre. To the larger motor can be attached when desired the air-pump, which supplies air under pressure on the one hand, and a vacuum-conduction on the other for use in the laboratories; the same motor also drives a pump for hot-water circulation in the building. A vacuum apparatus for concentrating serum, or for evaporating it to dryness, is situated in a special room near by. Inside it are a number of horizontally placed iron plates, in which hot water circulates. The serum in a thin layer in flat sterile glass evaporating dishes is placed on these iron plates; the apparatus is closed air-tight, and the air inside exhausted by the vacuum pump; the temperature is maintained at from 27 to 30 degrees C., and the evaporation goes on with great rapidity and without any injury to the labile constituents of the serum. After the evaporation has been carried far enough, filtered air is allowed to enter the apparatus and the product removed. When necessary the whole apparatus can be sterilized by passing a stream of superheated steam through it.

A large Buchner's press, capable of exerting a pressure of 350 atmospheres, forms a part of the outfit. My attention was also drawn to a special kind of protective paint which has proved very serviceable. As is well known, it is extremely difficult in bacteriologic workrooms to find a covering that will stand steam sterilization. In the Vienna Institute a Dutch-French substance called "ripolin" has been found very satisfactory. It has often been subjected to temperatures of 100 degrees C., and while the original white color has turned a little yellow, blistering or scaling has not occurred. The ripolin is therefore far more durable than Japan black or enamel paint.

The stables for the horses are models of cleanliness and order. It is discouraging to an American to think of how expensive it would be to keep the horses and the stalls at home in the princely way they are cared for here. It is easily possible in Austria and Germany to obtain a skillful, conscientious *Dienerschaft* with a moderate money-outlay; in America the cost of the same skill and help is almost prohibitive. The newer stables are so constructed that they can be subdivided into small, completely isolated compartments: the desirability of this arrangement is obvious when one remembers the necessity of isolating newly purchased horses until they have been proven to be free from disease, the separate stabling of especially inoculated animals, and the quarantine of infected animals. The institute has its own blacksmith constantly in attendance. Regular weekly visits are made by a veterinary surgeon, and he may be called on at any time in case of need. Professor Paltauf told me that many of the best horses used in serum manufacture developed amyloid; they have hemorrhages into the liver, become icteric and die. Nearly a dozen fine animals have been lost from this cause.

In view of the disappointing results with antistreptococcus serum elsewhere, it was a surprise to me to find that the particular antistreptococcus sera prepared in Vienna under Paltauf's direction are highly valued. The opinion there seemed to be unanimously in favor of the use of Moser's serum in scarlet fever and of Paltauf's new serum against streptococcus infections of the puerperium. The difference between these sera and that of Marmorek is this: The Vienna sera are prepared by direct inoculations of streptococci of human origin, the serum for scarlet fever by immunization against streptococci from the throats of actual scarlatina patients, the serum against puerperal infection by immunization against streptococci taken directly from human puerperal infections. The Viennese believe that the passage of a race of streptococci through animals makes it incapable of yielding results such as they get by their direct inoculations from human cases. An assistant of Chrobak's at a meeting of the *Aerztliche Verein* which I attended, reported a series of puerperal infections treated with the new serum, in which the favorable results obtained were truly striking. Every case in the series in which the infection was due to streptococci alone, it is asserted, was cured; bacteriologic study of the few fatal cases demonstrated mixed infections with other bacteria.

THE AERZTLICHE VEREIN.

The *Aerztliche Verein*, by the way, is superbly housed in Vienna, and it says much for the enterprise, generosity, and artistic sense of the medical profession of that city that it should have provided itself with such a home. The reception-rooms, auditorium, and library are admirably arranged, and it is not the practical needs alone of the busy medical men that have been considered; the exquisite furnishings, the balustrades, the group of busts of famous Vienna medical men, give the place an air of elegance and ease. I could not help but wish that the profession of Chicago and of other great American cities might soon, with the help of the excellent organization which has recently been going on in connection with the medical societies, see its way clear to supply the money for and to build similarly practical and beautiful buildings. The advantages of a permanent headquarters for the profession in a large city are almost incalculable. The benefits derived extend in a whole series of directions—not the least important of which is the social. Such a professional home goes far to elevate the standards of a group of men; it is an influence which tends to dignify, ennoble and refine the profession. At the time of my visit the Vienna gynecologist, Professor Chrobak, was president of the *Verein*, and Professor Paltauf was its secretary.

(*To be continued.*)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Acute and Chronic Nephritis.

In considering the treatment of nephritis it must be ascertained whether or not the condition is an acute or a chronic process; and if acute the cause of involvement of the kidney structure must be taken into consideration in outlining the treatment. If the process is a chronic one the clinical findings should show whether the tubal system is diseased to the greater extent or the toxic substances have chiefly involved the vessels along with an increase in the connective tissue formation; in other words, whether the diseased condition is chiefly parenchymatous or interstitial. The prognosis, of course, depends on whether it is acute or chronic. Even in the acute form it is a difficult task to forecast the outcome of the patient, as all patients are not alike, so for this reason, according to Sir Dyce Duckworth in the *Clinical Jour.*, London, the prognosis of any form of nephritis should be guarded, as all patients have their peculiarities and temperaments, diatheses or qualities which are peculiar to them. One man has a tendency in one direction and another in another. There is no medicine for disease, as this author tersely states, but for individuals. We do not treat disease, but patients. Some patients are much more vulnerable than others, especially those of a strumous diathesis. This sort of individual is vulnerable at all points, and if such a patient suffers from an acute nephritis the prognosis is not good, and may end in chronic nephritis. On the other hand, if a man suffering from acute nephritis is of good constitution and can obey the instructions of his physician and not expose himself to wet and cold, and observes care in regard to his diet the prognosis for complete recovery is good. In the treatment of acute nephritis the author recommends a warm bed, bread and milk diet, barley water and whey. Of the latter the patient may take two or three pints a day. He may also have arrowroot, bread and butter, crackers, and if he is very hungry he may be allowed a small amount of mashed potato. These patients should not have meat nor strong food.

If the urine contains much blood, as may be the case in acute nephritis, dry cupping should be employed. If he is strong, the author recommends that wet cupping be employed, and that from 12 to 15 ounces of blood be taken from the loins in this way, as there is direct vascular connection between the skin of the loin and the interior of the kidney. Warm poultices over the loins are also of great service. Antimony in the form of the wine is very good given in one-half dram (2.00) doses, combined with spirits of nitrous ether, and a solution of ammonium acetate.

At the onset of the disease, a calomel purge should be given, two grains combined with half a dram (2.00) of compound jalap powder and afterward give two teaspoonfuls of a confection containing from a half to one dram of the compound jalap powder. This treatment, according to Duckworth, clears the renal tubes and diminishes the dropsy of the limbs and face. The patient should be confined to the hospital until all the albumin has disappeared from the urine. Iron is another preparation which is of value in these cases given in the form of ammonio-chlorid of iron or Basham's mixture, and may sometimes be combined with digitalis. Fuchsin is also recommended in doses of from one to ten grains (.06-.65) daily, as it sometimes decreases the amount of albumin, and at any rate does no harm if it does no good.

CHRONIC BRIGHT'S DISEASE.

Croftan, in the *Ill. Med. Jour.*, is of the opinion that Bright's disease is produced by circulating toxins and that the cardiovascular changes precede the kidney changes, as the result. The source of these toxins is two-fold, the gastrointestinal tract and the products of metabolism. The liver does not functionate properly, and as a result there is incomplete elaboration of the food before it reaches the circulation. The management of a case of Bright's disease according to Dr. Croftan should be considered under: 1, prophylactic treatment; 2, symptomatic, directed primarily against the development of cardiovascular changes, and secondarily, against the nephritic changes. 3. The treatment of the patient as a whole.

TO PREVENT INTESTINAL PUTREFACTION.

The diet should be properly guarded and the stomach washed out if necessary. The author recommends especially in this connection the use of zinc sulphocarbolate given in doses of one grain (.06) each at frequent intervals, together with about twenty grains (1.30) of bismuth daily. If the zinc preparation is used in sufficiently large doses it will prevent the black stools of the bismuth, as it checks putrefaction, and thus prevents the formation of bismuth sulphid. The color of the stools, therefore, should govern the amount of the zinc salt given daily and when this is obtained the urinary evidence of bowel putrefaction will disappear, as shown by the reduction of indican, etc. The bile salts are also of value in this same connection.

To strengthen the heart and to reduce the blood pressure, small doses of digitalis are recommended, one drop (.06) of the tincture, three times a day, is a sufficiently large dose to render the heart less susceptible to the disturbing stimulation of the circulating toxins. Large doses of digitalis are contraindicated. Nitroglycerin is the best remedy to reduce the blood pressure. As adjuvants to these preparations the hot bath, rest in a warm bed, life in a warm, dry climate and massage are of value.

The author believes in a liberal diet and one which will least irritate the kidney and at the same time adequately nourish the patient. He condemns the use of an exclusive milk diet, as it must be given in enormous quantities to properly nourish the patient. If administered in such large quantities it causes flooding of the heart and arteries with water, and thus overtaxes them. It is deficient in iron, and in time leads to deficient hemoglobin, and its use, sooner or later, becomes monotonous. The diet, therefore, should be a mixed one, and should contain a moderate amount of albumin.

The amount of water should be restricted; for the kidney, when it becomes diseased, stops eliminating water as the first thing, consequently the practice of "flushing out" the kidney should not be encouraged. The chief advantage of "sweating" is to get rid of the water.

WITHDRAWAL OF SODIUM CHLORID.

The nephritic kidney fails in properly eliminating sodium chlorid, and, therefore, favors edema, as the salt draws water from the tissue by the process of osmosis. Consequently, the ingestion of salt should be restricted. The surgical treatment of decapsulating or splitting the capsule is condemned by this author.

USE OF WATER IN NEPHRITIS.

Broadbent, in an abstract in *Amer. Med.*, states that the use of water depends on the time when it is taken. A glassful taken night and morning makes it effective as an eliminant. Specific growth of the urine is a more important factor in this disease than the amount of albumin. The tension of the pulse is an indication in the prognosis and treatment. When a high tensioned pulse is present he employs a mild mercurial aperient. According to his statement, the effect on the arterial tension of a single grain of a mercurial preparation with slight aperient action is much greater than repeated liquid motions induced by saline; and the renal elimination is increased by the mercurials. This author believes, also, that the starting point of chronic nephritis is some impurity in the blood which acts as an irritant, that by its elimination the renal trouble may be prevented, and that calomel aids in this elimination. Acting on the basis that uremic convulsions are caused by interference with the cortical circulation of the brain, he frequently advises venesection in this condition, but when there is only threatened uremia he orders free purgation by calomel, which usually causes the symptoms to disappear, and the tension of the pulse to be reduced.

SURGICAL TREATMENT.

An account is given in the same periodical of six cases of Bright's disease operated on by P. Rosenstein, and decapsulation of the kidney performed with negative results in every case. The author's conclusions are as follows: Decapsulation of the kidney in grave Bright's disease is a dangerous operation; a permanent cure has not been recorded in any case; improvements were noted, but in one of the improved cases the albumin and casts continued to exist, only the edema disappearing; in the other, headache and scotoma persisted.

INDICATIONS FOR TREATMENT.

The indications for treatment of chronic Bright's disease may be summed up as follows:

1. Early in the disease, to reduce the effect of the toxic substances, in the circulation, on the heart, arteries and kidney substance.
2. When the arterial tension becomes pronounced, to use means to reduce it.
3. Support the heart in well-advanced cases and promote elimination by bowels, skin and kidney.

In carrying out the first point the diet should be light, nonirritating, but not confined to a strictly milk diet. It should include well-cooked vegetables and a small amount of farinaceous and animal food; at the same time produce free elimination by the bowels. The arterial tension may be lessened by the use of calomel aperients and nitroglycerin. To check the progress of arteriosclerosis, potassium iodid is recommended by some authorities.

In the treatment of the anemia Weir-Mitchell recommends large doses of the tincture of ferric chlorid, from 30 to 60 minims (2.-4.) three times a day.

To support the heart early in the disease, caffein, spartein sulphate or moderate doses of strychnia are of value. Later in the disease, when the heart has become greatly enlarged as the result of its efforts to overcome the great tension in the arteries and vessels of the kidney, strophanthus and later digitalis are necessary. Strophanthus has the advantage over digitalis in that it is a good heart stimulant and does not contract the arteries as does digitalis, but it has the disadvantage, as stated by some authorities, of irritating the kidneys. The ordinary pill of calomel, squills and digitalis is a valuable combination in the treatment of this disease.

Hydrogen Dioxid in Dyspepsia.

Gallois and Courcoux of Paris have been studying the action of hydrogen dioxid on the digestion, experimenting on dogs with a Pawlow fistula. They claim that it has a pronounced effect in increasing the amount of gastric juice secreted and the proportion of free hydrochloric acid, thus secondarily enhancing the digestive power of the gastric juice, the proportion of pepsin being always higher than under other conditions. Clinical experience also showed that it arrested the vomiting of pregnancy, the effects not being apparent at once, but suggesting that it removed the cause. This seemed to be the case also in certain gastrointestinal troubles, especially hypopepsia and diarrhea. As it combines the properties of promoting digestion and disinfecting the bowels, it is thus especially indicated in hypopeptic dyspepsia with abnormal fermentation, and is particularly useful for infants. The results seem to be better the more recent the onset of the diarrhea. They add in their article in the *Gaz. Med. Belge*, Jan. 5, 1905, that a Russian physician, Novicor, prescribes it in dyspepsia in the formula of 6 gm. (ʒiss) of hydrogen dioxid at 12 volumes; 85 gm. (℥iiss) of distilled water, and 15 gm. (gr. iv) of syrup of orange flowers, giving a tablespoonful every two hours. They prefer to give it in milk or water, 10 drops of the dioxid to 100 gm. (qt. i) of milk, for infants; for adults, about a table spoonful in a quart of water, sipped as a beverage.

Atropin in Too Strong Solution.

Our attention has been called to an error. An abstract on "the treatment of purulent ophthalmia," Jan. 28, 1905, was quoted from *American Medicine*, Dec. 31, 1904, in which the statement is made that "a 4 per cent. solution of atropin can be used in the eye." It is probable that "4 grains to the ounce" is what was meant.

Medicolegal.

Duty of Injured Person.—The Supreme Court of Illinois says, in Chicago City Railway Company vs. Saxby, a personal injury case brought by the latter party, that it was the duty of such party to use reasonable care to effect a speedy and complete cure of the injury which she sustained by being thrown on the street from the company's car, and, to that end, she was required to exercise reasonable care to employ physicians of ordinary skill and experience to treat her, and other means to effect a cure of her injuries. She was not, however, required to employ the highest medical skill which might be found. All the law required was that she exercise such prudence as men and women of ordinary judgment, under like circumstances, would exercise in the choice of physicians and the means to be used to effect a recovery. She was not an insurer, bound to act at her peril; and if she exercised reasonable care in selecting her physicians, and in the employ of other means for her recovery, if her physicians made a mistake in the treatment applied by them to her, or by the means employed failed to effect a cure, then she might recover for the entire injury which she had sustained, as the law, if the injured person uses ordinary care in selecting a physician, and in the employment of other means to effect a cure, regards an injury resulting from the mistake of a physician, or from a failure of the means employed to effect a cure, as a part of the immediate and direct damages which naturally flow from the injury. If it be conceded that she had tuberculosis in her system, and that the same was developed in the knee by reason of the injury thereto, or from the treatment she received in the endeavors made to effect a cure of the fracture of the neck of the femur, it could not be said that the diseased condition of the knee was not a consequence which naturally and ordinarily might not follow as a result of the injury caused by the negligent act of the company.

Admissibility and Use of Skiagraphs.—The Supreme Court of Illinois says, in Chicago and Joliet Electric Railroad Company vs. Spence, a personal injury case brought by the latter party, that, as the case might be again heard, it was necessary it should consider the insistence that the trial court erred in permitting the introduction in evidence of a skiagraph, or *x*-ray photograph, of a portion of the chest and body of the party suing. The skiagraph was made by an expert, who testified he was an *x*-ray expert, and was regularly engaged in taking such photographs for physicians; that he took the negative from which the photograph was developed, and that he developed the photograph; and that it was an accurate and correct representation, etc. It was intended to show by the skiagraph that the party's heart had been displaced, that the walls of that organ had become thick, and that an abnormally heavy tissue had formed on the walls of his heart. The testimony of the *x*-ray expert who had taken the skiagraph tended to show the picture correctly represented the condition of the heart of the party. Photographs taken by the *x*-ray process are admissible in evidence after proper preliminary proof of their correctness and accuracy has been produced. And the Supreme Court thinks the testimony of the *x*-ray expert who made the skiagraph was sufficient to justify the court in ruling that the picture should be admitted in proof. Subsequently, when the company was introducing testimony in chief, another *x*-ray expert was produced in its behalf. This witness gave testimony tending to show that the skiagraph had not been properly taken, and expressed the opinion that the picture was of little or no value as a representation of the heart and other portions of the body of the party suing. But the court was not asked to exclude the picture because of this adverse criticism; nor does the Supreme Court think the motion to exclude should have been granted, had it been interposed. It further says that it was not error to allow the jury to take the skiagraph with them when they retired to consider their verdict. Paragraph 56 of the practice act authorizes "papers read in evidence, other than depositions," to "be carried from the bar by the jury." "Papers in evidence" clearly embrace photographs or skiagraphs offered and received in evidence. One of the definitions of the word "read" given by Mr. Webster is "to discover or understand by characters, marks, features, etc.; to gather the meaning of by inspection; to learn by observation." Photographs or skiagraphs produced in evidence on a trial before a jury are, within this definition, "read" in evidence, and may be taken by the jury on their treatment to consider and determine the cause. 12 *Ency. of Pl. and Pr.* 591, 592; Barker vs. Perry, 67 Iowa, 146.

Liability of City for Smallpox Expenses.—The Appellate Court of Indiana, Division No. 1, says, in City of Frankfort vs. Irvin, that the statute of that state makes the mayor and common council of an incorporated city, not having a board of health by statute or ordinance, a board of health for the city. The record in this case contained evidence from which it could be said that there was some danger of an epidemic of smallpox in the city. At a special meeting of the common council, called to consider the situation, a special committee was appointed, consisting of three councilmen, one of whom was designated as chairman, and to this committee was referred the matter of looking after the smallpox in the city. It appeared that soon afterward there were a number of cases of smallpox in the city, and that most of the acts done with reference thereto were done by the chairman of this committee. It did not appear that this chairman did anything that the city council, acting as a board of health, might not have done itself. It did not appear what authority was given this committee, or its chairman, in the matter; but it did appear that the city ratified a part of the work of this committee by afterward paying bills contracted in relation to the management of the pesthouse. The court thinks it appeared from the evidence that what this committee and its chairman did was one entire transaction, which should be repudiated or ratified as a whole. It says that the statute makes it the duty of the board of health to take prompt action in all cases to arrest the spread of contagious and infectious diseases. It is left to the discretion of the board as to how this may best be done. What power the board has, as against the individual, to confine a person afflicted with smallpox in a pesthouse, the court says that it had nothing to do with in this case. The board took such measures as it thought best to protect the health of the people at large, and was liable for such expenses as were properly attributable to measures taken for the prevention of the spread of the disease. And the court thinks it can be said that the employment of a nurse to care for a person afflicted with smallpox is an essential precautionary measure to prevent the spread of the disease. Under the circumstances disclosed by the record, the common council, acting as a board of health, could have legally contracted with a party for his services as a nurse. Such a contract made through the agency of a committee or other authorized person is no less binding than if made by the city itself. The extent of the authority of the person or persons empowered to act must necessarily depend to a large extent on the conditions existing in the particular case. It was immaterial that the pesthouse was located outside the city limits. The fact that it is the duty of the overseer of the poor, and not of the city, to make provision for poor and indigent persons, does not relieve the city from liability for necessary expenses incurred by it in preventing the spread of the disease. Nor does it prevent the city from legally contracting to pay the services of a person who assists in the burial of a person who has died of the disease while under the control and charge of the city's health board. The proper and prompt burial of a person who has died of smallpox may be as necessary in preventing the spread of the disease as the proper care of a person while afflicted with the disease.

2. **Rectal *Alimentation*.**—Edsall and Miller have continued their experiments in the matter of rectal feeding, especially in the direction of finding some method of artificially preparing fats so that a greater degree of absorption may be secured. With this purpose in view they carried out experiments on two different lines: 1. They tried to provide their fats in the form of a soap that would be easily prepared and administered, and to investigate its absorption when given by rectum. 2. Search was made for a good emulsion of fat that would remain emulsified after its introduction into the bowel. Their results were such as to convince them that it is impossible by any methods now available to administer successfully sufficient soap to make it of decided nutritive value. They were unable, after repeated attempts, to find any method of making a soap that could be readily prepared for clinical purposes or would be unirritating. Their results with an artificial fat emulsion, a mixture of alkali albumin and cod-liver oil, were somewhat more encouraging. They believe that further study may determine that the clinical value of nutritive enemas may be increased, though it is still a question whether it ever will be possible to maintain nutrition in this way. They believe that the functions at present served in most cases by nutritive enemas are: first and most important, to provide fluids and various inorganic salts for the tissues; 2, to provide, perhaps, from a third to a sixth of the requisite amount of food; 3, to prevent the anxiety of friends and patients that would be produced by giving no food.

3. **Tuberculous Cavities in the Lung.**—Allyn insists on the importance of a thorough examination and following an orderly progression in developing physical signs in attempting to arrive at a diagnosis of tuberculous cavities in the lung. The most trustworthy signs are to be found in deficient expansion and flattening of the chest wall over the cavity; in a percussion note which is often a high-pitched tympany, especially if percussion is made with the mouth open, but which may be only a muffled sound or a dull or flat sound; in pectoriloquy, particularly the whispering variety; in breath sounds which are cavernous, tubulo-cavernous, tubulo-amorphic or amorphic; and in a multiplicity of râles, chiefly moist râles, which, after coughing, may have a resonating quality.

4. **Diet After the Age of One Year.**—Griffith advises that the infant should be weaned at from the age of ten to twelve months. When possible this should be accomplished gradually, only one bottle of food being given at first, and this of a strength less than mother's milk, thus enabling the child to accustom itself to the new food. The number of bottles and the strength of the mixture are increased gradually until at the age of a year the food should consist of milk slightly diluted. The child should be weighed systematically twice a week during the weaning, in order that no undiscovered loss of weight takes place. After the child has been weaned entirely and has become accustomed to the new artificial food, it is well to add to the food a concentrated amylaceous substance such as barley jelly or arrowroot jelly. The proportion of two rounded tablespoonfuls of barley flour or arrowroot to a pint of water, cooked in a double boiler for ten or fifteen minutes, makes the proper strength. This may be added to the food in the proportion first of one and later of several teaspoonfuls to each bottle, the addition to be made while the cereal substance is still hot. The number of feedings during this period has been reduced from three hours to three and a half or four hours, depending on the requirements and habits of the child. The amount of nourishment should be from 8 to 10 ounces at a feeding. After the first year Griffith advises the following diet:

DIET FROM 1 YEAR TO 18 MONTHS.

Breakfast (6 to 7 a. m.).—1. A glass of milk with stale bread broken in it, or one of the numerous good breakfast foods on the market. 2. Oatmeal, arrowroot, wheaten grits, farina, hominy grits, etc., made into a porridge and well cooked, and with the milk mixture in use poured over it. 3. A soft-boiled or poached egg with broken bread in it, and a glass of milk.

Second Meal (10 a. m.).—A glass of milk.

Dinner (1:30 to 2 p. m.).—1. Bread moistened with dish gravy (no fat) beef tea or beef juice; a glass of milk. 2. Rice or grits moistened in the same way; a glass of milk. 3. A soft-boiled egg and stale bread thinly buttered; a glass of milk. Rice, sago or tapioca pudding or junket, in small quantities as dessert with any of these diets.

Fourth Meal (5 p. m.).—A glass of milk or some bread and milk.

Fifth Meal (9 to 10 p. m.).—A glass of milk.

Diet from 18 Months to 2 Years.

Breakfast (7 a. m.).—1. A glass of milk with a slice of bread and butter or a soda, graham, oatmeal or similar unsweetened biscuit. 2. A soft-boiled egg with bread and butter and a glass of milk. 3. Porridge, as described in the previous list.

Second Meal (10 a. m.).—1. Bread broken in milk. 2. Bread and butter or a soda or other biscuit with a glass of milk.

Dinner (2 p. m.).—1. Boiled rice or a baked potato, mashed and moistened with dish gravy or beef juice; a glass of milk. 2. Mutton or chicken broth with barley rice in it; some bread and butter, and some sago or rice pudding made with milk. 3. A small portion of minced white meat of chicken or turkey, or rare roast beef, beefsteak, lamb, mutton or fish; bread and butter; a glass of milk.

Fourth meal (5 p. m.).—1. Bread and milk. 2. Bread and butter and a glass of milk.

Diet from 2 to 3 Years.

Breakfast (7 to 8 a. m.).—1. A small portion of beefsteak, with oatmeal, hominy grits, wheaten grits, cornmeal or other cereal porridge with plenty of milk. 2. A soft-boiled egg, bread and butter and a glass of milk.

Second Meal (11 a. m.).—1. A glass of milk with bread and butter or with a soda or other biscuit. 2. Bread and milk. 3. Chicken or mutton broth.

Dinner (2 p. m.).—Roasted fowl, mutton or beef cut fine; mashed baked potato with butter or dish gravy on it; bread and butter. As dessert, tapioca, sago or rice pudding, junket or a small quantity of raspberries, peaches, grapes without seeds, orange juice or of stewed apples or prunes.

Supper (6 p. m.).—1. Bread and butter. 2. Milk with soda or similar biscuit or with bread and butter.

Diet After Three Years.

FOODS PERMITTED.

Meats.—Broiled beefsteak, lamb chops and chicken; broiled liver; roasted or boiled beef, mutton, lamb, chicken and turkey; broiled or boiled fish; raw or stewed oysters.

Eggs.—Soft-boiled, poached, scrambled, omelet.

Cereals.—Light and not too fresh wheaten and graham bread, toast, zwieback; plain unsweetened biscuit, as oatmeal, graham, soda, water, etc.; hominy grits, wheaten grits, cornmeal, barley, rice, oatmeal, macaroni, etc.

Soups.—Plain soup and broth of nearly any kind.

Vegetables.—White potatoes, boiled onions, spinach, peas, asparagus except the hard parts, string and other beans, salsify, lettuce, stewed celery, young beets, arrowroot, tapioca, sago, etc.

Fruits.—Nearly all if stewed and sweetened; of raw fruits, peaches are one of the best; pears, well-ripened and fresh raspberries, strawberries, blackberries, grapes without the skin and seeds, oranges.

Desserts.—Light puddings, as rice pudding without raisins, bread puddings, etc., plain custards, wine jelly, ice cream, junket.

FOODS TO BE TAKEN WITH CAUTION.

Kidney, muffins, hot rolls, sweet potatoes, baked beans, squash, turnips, parsnips, carrots, egg-plant, stewed tomatoes, green corn, cherries, plums, apples, huckleberries, gooseberries, currants.

FOODS TO BE AVOIDED.

Fried food of any kind; griddle cakes; pork: sausage, highly-seasoned food; pastry; all heavy, doughy or very sweet puddings; unripe, sour or wilted fruit; bananas, pineapples, cucumbers, raw celery, raw tomatoes, cabbage, cauliflower, nuts, candies, preserved fruits, jams, tea, coffee, alcoholic beverages.

It is important that milk remains the chief article of diet throughout early childhood. Broths are serviceable as food only through the cereal addition with which they are thickened. Although rashness on the part of the mother in experiments on new foods is to be condemned, too great caution resulting in too long a continuance with insufficient food is equally harmful. Children should not be fed too frequently nor should they be given too much starch, as that is a frequent cause of illness. The age and need of the child rather than the teeth should be the guide in determining when the giving of meat may be commenced. No candies, cakes or other such articles should be given. No food should be allowed between meals, although if there clearly be real hunger a small glass of milk may be given at times, but even this is to be discouraged as a custom. During very hot weather the diet should be reduced greatly in variety and in amount. The child of 2 years had better be put temporarily on the diet of a child of one year. Illness may often be avoided by following this plan.

14 Cause of Seasickness. Charles W. Hogg.

7. **Diagnosis of Renal Calculus.**—Johnson discusses the clinical history of renal calculus, especially with reference to diagnosis. He details his experiences in 125 cases with the *x*-ray used as a diagnostic agent and has found that a positive diagnosis of kidney stone by the *x*-rays is reliable and of great practical value. The same may be said of a negative diagnosis, up to a certain limit. If pictures of the proper quality are obtained, calculi of oxalate of lime and phosphates can be excluded. Pure uric acid calculi can not. Failures are due to: 1, The great thickness of the body of the patient; 2, imperfect working of electrical apparatus; 3, improper handling of the photographic plate in the dark room, and 4, imperfect photographic plates. To insure success in the radiography of kidney stones the following conditions must be fulfilled: The electrical current used to excite the tube must be of high voltage and of considerable amperage. The best coils and large static machines answer this requirement perfectly. The *x*-ray tube used must permit the passage of such a current continuously for several minutes without much change in internal resistance, although the resistance or vacuum of the tube is relatively low at the start. A tube of relatively low resistance produces rays showing on the photographic plate slighter differences of density in the structures through which the rays are passed, but, as the result of the passage through such a tube of a powerful current the tube usually becomes heated with a further fall of resistance and the production of rays of inadequate penetrative power. A tube of high resistance tends to preserve its vacuum resistance better, but the *x*-rays given off from a tube, the resistance of which is very high, possess the penetrative power to a high degree; they penetrate all the structures of the body more nearly in an equal manner and thus produce radiographs showing but little contrast betwen tissues of different densities. His best pictures have been taken with the Wehnelt electrolytic interrupter, with rather a heavy platinum electrode having a considerable amount of platinum exposed in the acid, thereby permitting the use of a current of considerable amperage and relatively slow interruptions. The exposures for large, stout people have varied from ten to fifteen minutes, with anticathode about thirty inches from the photographic plate. For thin individuals these exposures have been shortened one-half.

9. **Insects in Transmission of Disease.**—Albert discusses the diseases transmitted by insects: the insects responsible for such transmission: the manner in which such transmission may occur, and the agents that may be used to eliminate the insect factor in the transmission of disease.

11. **Litten's Diaphragm Phenomenon.**—Berkeley suggests the term "phrenic wave" for this phenomenon, which is the visible descending and ascending wave associated with the respiratory movements of the diaphragm in the lower zone of the thorax. To students in physiology the phrenic wave is useful as a demonstration of the respiratory movements of the diaphragm. When unbroken and over three inches in extent on both sides it is a good indication of healthy lungs, and should be incorporated as such into life insurance examinations. It is an easy and practical substitute in many cases for the expensive and laborious *x*-ray examination of the movements of the diaphragm, when such an examination is desired. When diminished markedly on both sides, low down in the thorax, and more marked behind than in front, it is an excellent sign of asthma and emphysema. When absent or nearly absent, on one side only, it is a useful confirmatory sign of a variety

of conditions which may be suspected from other signs, particularly pleurisy and early tuberculosis. When absent on both sides no conclusion of any kind is really justifiable, unless the patient has been known to have had good waves previously.

20 *Case of So-called Traumatic Asphyxia. R. Winslow, Baltimore.

16. **Afebrile Estivo-Autumnal Malaria.**—Pomeroy reports the case of a man who contracted estivo-autumnal malaria in New York City, not having been outside of the city in fifteen years. His regular work was unloading vessels from all parts of the world. During the fall of 1900 he began to sufferr from chills and sweats. The attack lasted about three weeks, during which time he was bed-ridden and his skin became yellow. Recovery was slow, and from time to time he suffered from chills followed by sweats. Loss in weight became quite apparent. The affection was pronounced malaria and his physician gave him some pills, after taking which he invariably improved. Recently the chills and sweats recurred with renewed severity. While they were very irregular, they occurred some time between 5 a. m. and 9 p. m. Shortly after entering the hospital he had a violent chill, followed by a profuse sweat, but his temperature was normal, both before and after chill, not going above 99. These chills proved very irregular, appearing often without being followed by a definite sweat, and, again, the reverse would be the case. Examination of the blood showed the presence of extracellular crescentic and ovoid bodies, the latter preponderating during the afternoon and the former during the forenoon. The patient was placed on quinin sulphate in perforated capsules, 15 grains every four hours, and one-half ounce of Warburg's tincture before meals to stimulate his appetite. Saline catharsis was used to relieve constipation and to increase elimination. Under this treatment, recovery was prompt. The points of interest in the case are: 1. An estivo-autumnal infection having its origin in New York City. 2. Chills and sweats without temperature—the latter appearing only when quinin had been administered and then not rising above 100.2.

20. **Traumatic Asphyxia.**—The history of Winslow's case is as follows: An elevator conductor had occasion to get on top of a car and told an assistant to lower it, but by mistake the elevator was raised and the man was caught between the ceiling and the top of the car. He was forcibly bent down so that he sat on his heels, while his head was forced down to the roof of the car. He was kept in this position for some moments, during which time he felt as if his head and chest would burst and he could not breathe. He did not lose consciousness, but suffered considerable pain. After his release he had bloody expectoration and some epistaxis. Examination of the chest revealed fractures of the fourth, fifth and sixth ribs on the left side, with some emphysematous infiltration of the subcutaneous connective tissues. There was some cough. A contusion was seen on the right ear. There was no blood in the urine nor was he unable to empty the bladder. A lacerated wound was found around the rectum, which had evidently been made by the heel of his shoe as he was doubled up by the pressure. Sight and hearing were not impaired. The pupils were equal and responded to light. There was an extensive extravasation of blood under each conjunctiva and a bluish discoloration of the head, face and neck to the level of the cricoid cartilage. It was punctiform in character, like the eruption of scarlet fever, but blue instead of red. It did not disappear nor change materially on pressure. The temperature rose to 100.8, dropping to normal in three days. The pulse rate was 120 and gradually dropped to 80. The color of the skin gradually faded but had not entirely disappeared when he was discharged, on the twelfth day. No special treatment was instituted except an ice bag to the chest and, subsequently, adhesive strips, with enough morphin to relieve the pain. Microscopic examination of a piece of skin removed from the side of the neck showed practically no alterations. The capillaries here and there were more or less distended with blood, but no blood was found anywhere in the tissues outside of the blood vessels.

25 *Growth of Bone in the Tonsil. William W. Carter, New York.
26 *Report of Three Cases of Intestinal Anastomosis by the Connell Suture. H. H. Sinclair, Walkerton, Ont.

21. **Sanitary Conditions in Cuba and Panama.**—Gorgas discusses the progress and results of sanitary measures in Cuba, particularly with reference to the extermination of yellow fever, and outlines the steps that will be taken to render the Isthmian Canal zone as free from malaria and yellow fever as is Havana.

22. **Intramuscular Hemorrhage from Muscular Action.**—Smith emphasizes the distinction to be drawn between those cases in which the escape of blood within the intact sheath of a muscle is the important factor and those in which laceration of muscle and sheath plays the principal part. He says the former variety may give rise to greater immediate suffering and to more lasting impairment of function than the latter. Rupture of individual muscle fibrillæ, the result of a violent contraction, is comparatively common, even in a healthy muscle. Almost any muscle may be involved, but those that act through tendon of achilles suffer most because of the greater strain to which they are subjected. Other causes of rupture are excessive stimulation, irregular contraction and inco-ordination of the muscle fibers. The amount of hemorrhage depends more on the freedom with which the effused blood can escape into the neighboring tissues than on the size of the vessel torn across. The degree of pain felt by the patient depends on the amount of pressure or tension within the blood sac. Smith cites two cases of hemorrhage into the calf muscles due to muscular action in which a limited amount of blood was effused into a confined space, with the result of causing much pain and protracted disability. In two other cases cited the muscle was torn completely across, the calf muscles in one and the sterno-cleidomastoid in the other, but the suffering was comparatively slight and the disability of short duration.

24. **Diagnosis of Renal and Ureteral Calculi.**—Fowler emphasizes the importance of early diagnosis in these cases because by early surgical interference we can save the kidney and also procure relief for the patient. Moreover, we avoid alarming and distressing complications and a final resort to more serious operations. In the early stages, nephrolithotomy offers a perfect cure, is not dangerous, and is attended by a very low mortality.

25. **Growth of Bone in Tonsil.**—Carter narrates a case, female, aged 22, in which one tonsil was found to contain areas of hyalin cartilage undergoing osseous transformation, and other areas in which bone was being formed directly from fibrous tissue; while in still others the transitional stages from fibrous tissue through cartilage to bone were observed. Carter expresses the belief that in these cases the bone originates from metaplastic changes in connective tissue and not from the branchial arch, but since bone does not develop in every tonsil that has been subject to proliferative connective tisue changes, we must assume, when it does occur, some local predisposing tendency to its formation.

26. **Experience with the Connell Suture.**—Sinclair [illegible]

three cases in which he made use of the Connell suture. The first was a case of strangulated inguinal hernia; the second, gangrene, the result of a volvulus; the third, a retrocolic gastrojejunostomy for perforated gastric ulcer. The three cases made uneventful recoveries.

33 *Treatment of Hemorrhoids by the General Practitioner. T. Chittenden Hill, Boston.
34 Consumption and Its Borderland, Public and Professional Concern. Paul Paquin.

31. **State's Relation to the Epileptic.**—Copp discusses the obligation of the state to epileptics and the protection it requires for its own welfare. In addition to legislative efforts, he advises that the state should provide the following:

> 1. A center for study, research and teaching in relation to epilepsy, well officered and equipped, to afford scientific treatment to patients both within its care and at home, through advice to indigent parents and friends who may wish to avail themselves of the aid, and, in conjunction therewith, schools for elementary education, manual training and persistent drilling into habits of doing simple, everyday acts of helpfulness to the family or the institution.
> 2. Colonies, independent or associated with such a center, which the adult epileptic, thus trained, may enter and find a home in place of isolation in society, and industrial opportunities graduated to his capabilities under conditions suited to his peculiarities and to the utilization of his productive energy.
> 3. Custodial provision for the infirm, intractable and insane epileptic.

The trend of this policy is toward segregation of epileptics, both in the classification for public wards and apart from the general community. Its successful issue would afford the chief check on hereditary transmission of the degenerative taint.

32. **Tuberculosis Problem.**—Otis says that in order to stamp out tuberculosis it is essential, in addition to the measures usually followed, to promote conditions of wholesome living, to teach the people the elements of personal and house hygiene, and to teach what wholesome living is and how to obtain it.

33. **Treatment of Hemorrhoids.**—Hill says that the great majority of cases of hemorrhoids, of whatever form, can be treated radically, satisfactorily and with little discomfort to the patient at the physician's office. The after-treatment of these cases requires careful attention. The bowels, as a rule, should be confined for forty-eight hours. On the second night half a dram of fluid extract of cascara should be given, and sufficient thereafter to secure daily evacuations. The anal region should be kept scrupulously clean, and a pad of cotton-wool wrung out of bichlorid of mercury solution, 1 to 1,000, placed over the anal orifice is more acceptable to most persons than a dry dressing. Good drainage must be secured and the necessary topical applications made to induce rapid healing. Should there be much pain or soreness (which is rarely the case), it can be relieved by anodyne suppositories, morphia, cocain, or combinations of both. An irritable or hypertrophied external sphincter is occasionally the cause of pain after these operations. This complication can be avoided by a complete division of both layers of the muscle, a painless operation, under local anesthesia. On no account should the internal sphincter be damaged, as incontinence might follow.

43 Bezold's Mastoiditis; Report of Three Cases. S. Oppenheimer, New York.

40. **Throat Complications in Typhoid.**—Quinlan calls attention to throat complications of typhoid, such as pharyngitis, laryngitis and tonsillitis. The clinical history of these affections is described at great length and the literature on the subject is reviewed carefully. Quinlan asks that more attention be given these complications by the general practitioner, as they are of greater importance than is usually believed. A laryngitis occurring in the course of typhoid always modifies the prognosis. Therefore, any symptom pointing to an involvement of the throat should be investigated thoroughly and proper treatment instituted.

51. **Operation for Entropion.**—Hall describes an operation devised by him which he says is efficient for the relief of trichiasis and of organic *entropion* of the lower eyelid, and does not require excision of any tissue. The procedure consists of three steps: 1. Incision of the conjunctiva and tarsal plate.—The writer's, or preferably Ewing's, modification of Desmarres' *pince anneau* is applied, the base plate being in contact with the skin of the lid. An incision parallel with the lid margin is made at a distance of two millimeters from the margin, extending from a point one or two millimeters external to the lower punctum lachrymalis to a point one or two millimeters from the external canthus. The incision is made with a cataract knife or with a small scalpel, and includes the conjunctiva and entire depth of the tarsus. The cut is made obliquely from behind downward and forward. 2. Exposure of the lower margin of the tarsal plate.—The lid clamp is released and reversed, that is, the base plate is applied to the conjunctival surface. An incision is made along the whole extent of the lower margin of the tarsal plate. The lower border of the tarsus is then exposed by dissection and retraction of the tissues. 3. The placing of the sutures.—Three or four silk (English black, No. 1) sutures are then passed. The needle is entered from the conjunctival surface of the first wound and is passed obliquely from behind upward and forward, the upper part of the lid being held firmly with ordinary fixation forceps. The needle is then made to bite in the lower margin of the tarsus, and, lastly, it is passed through the lower lip of the cutaneous wound. The sutures are then tied. The effect of tying them is to produce a *renversement* of the upper segment of the lid, the cilia being directed forward, or forward and downward. The gaping wound in the tarsus heals by granulation. The sutures are removed at the end of four days.

28. **Natural Gastric Juice as a Therapeutic Agent.**—Rollin has made use of the gastric juice obtained from dogs in the treatment of stomach affections during the past three years. He obtained the gastric juice directly from Pawlow and repeated tests confirmed its efficiency as a digestant. With the exception of one patient, a woman, who complained that the gastric juice of a dog was too sour and who preferred the gastric juice of the pig, none of the patients objected to the taste of the fluid, even after partaking of it for several years. The 12 cases treated consisted of nervous dyspepsias, subacid and anacid gastric catarrhs. The average dose was 200 c.c. a day taken with the noon and evening meals. On several occasions, two of his patients had to substitute dilute hydrochloric acid for the gastric juice, the supply having given out, and they both stated emphatically that the therapeutic effect of the acid was not as great as that of the gastric juice. Rollin obtained equally good results from the gastric juice in all the cases treated and unhesitatingly subscribes to Pawlow's statement that the natural gastric juice of the dog is the digitalis of the stomach. The history of 10 cases is given in detail. Results were good in all.

32. **Diet in Chronic Diffuse Intestinal Catarrh.**—Rosenheim states that it is impossible to lay down a diet for all cases which is non-irritating and easily assimilable. So far as milk is concerned, although it oftentimes proves exceedingly useful in these cases when given in small quantities, yet, for the majority of patients, it had best not be given. Experience has shown him that if the small bowel is put at rest for a short time by giving some mild diet, other than milk, it is possible to give milk later, and with good result. In many cases, even very mild ones, it is advisable to abstain from milk for months. Rosenheim goes so far as to forbid using milk in the preparation of foods and drinks until the bowel has become perfectly quiet. During the first few weeks of the dieting of all his patients, milk never enters into the bill of fare. Disease of the large bowel, even though it may be advanced, does not contraindicate the use of milk; on the contrary, milk, specially when it is the only food taken, is exceedingly useful. In achylia gastrica and in hyperchlorhydria, milk, as a diet, occupies first place, but it should be omitted when there is an associated catarrh of the small bowel. In the majority of these cases, it is well to begin by prescribing a diet containing 120 or more grams of egg albumin, 200 to 250 grams carbohydrate; 40 to 50 grams fat and consisting of meat, fish, eggs, some sugar, wheat bread or zweibach, rice, farina, sago, macaroni, bouillon, broths, butter, tea, and red wine. Meat ought to form a considerable part of the diet in the majority of these cases. Although the small bowel, even when diseased, is well able to digest albumins, yet care must be taken not to give this in too large amounts, so as not to overtax the digestive capacity of the bowel. Changes in the diet must be made carefully and slowly, watching for the slightest manifestation of disturbances due to the change in diet. In those cases in which a neurosis is an etiologic factor, proper hygienic treatment must be given in addition to the dietetic.

33. **Therapy of Stomach Affections.**—Leo cites a case of gastroxynsis in which all the usual therapeutic measures failed to give any relief. Finally, he resorted to the use of cold douches for two or three minutes, the patient going to bed immediately afterward. This controlled the pain and vomiting for about two hours, and inasmuch as the man took four or five of these cold douches every day he experienced considerable relief. The second case cited is one of very severe gastralgia accompanying a chronic gastritis with subacidity. Lavage with solution of silver nitrate and other medicinal agents, including hydrochloric acid by mouth, proved futile. A mixture of pepsin and hydrochloric acid (10 parts of each in 50 of distilled water) yielded immediate relief and the patient is improving steadily. Leo calls attention to the anesthetic effect of this mixture, a most unusual one, due probably to its peptonizing action.

38. **Talma Operation in Eight-Year-Old Child.**—Milchner cites the case of a girl, 8 years old, suffering from an atrophic alcoholic cirrhosis of the liver, slight jaundice, extreme grave anemia and ascites. Medicinal treatment proving futile, he decided to do a Talma operation. The omentum was very thin and anemic, and showed no adhesions. The phlebectasia so common in liver cirrhosis was absent. An omentopexy did not relieve the ascites. Nevertheless the veins of the chest and abdomen soon became considerably dilated, and a typical caput medusæ formed. Milchner calls special attention to the absence of venous dilatation in the omentum as a probable cause of failure in producing the desired results by performing a Talma operation. On the other hand, his case proves that the success of the Talma operation is not dependent entirely on dilatation of the omental veins, and that the ascites accompanying cirrhosis of the liver is not always the result of congestion in the portal system.

39. **Embolism of the Lung Following Laparotomy.**—Gebele reports clinical and experimental experiences which show that a large percentage of the lung affections observed after laparotomy are due to embolism. In experimenting on 40 rabbits he noted after laparotomy an embolic lung affection in 12, and an embolic pneumonia in 4. Embolism, therefore, should be regarded as an important factor in the development of lung complications after abdominal operations. About a third of the lung infarcts are followed by pneumonia. Infection is indispensable, but this may occur primarily with the embolus or may follow later. Embolic pneumonia is hemorrhagic at first, before there is abscess formation, and it is usually insular, the foci generally locating beneath the pleura. He reviews the experiences of others, especially Mikulicz' report of 143 cases of pneumonia occurring consecutive to 1,781 laparotomies, almost half of the pneumonias terminating fatally. Gebele's article issues from von Angerer's clinic at Munich, and reports 77 or 6.43 per cent. cases of pneumonia following the laparotomies between 1892 and 1902. Out of the 77 cases 14 (1.17 per cent.) were of embolic origin, and 8 were suppurative pneumonia. He was unable to detect any special connection between the nature of the operation and the embolic complications.

40. **Complicated Fractures.**—Klauber reviews the experiences at the Prague clinic (Wölfler's) during the last [illegible] years. The proportion of cases treated conservatively is increasing every year.

43. **Differential Sign of Varix and Femoral Hernia.**—[illegible] states that when the varix is compressed with the finger

and then the compression is abruptly removed, but with the fingers still in contact, a distinct buzzing is felt similar to that felt over the thorax in certain cardiac defects.

50. **Pancreas Necrosis.**—Boehm regards gallstones as an important factor in the development of necrotic processes in the pancreas. He reports 6 new cases of necrosis of this organ, and emphasizes the necessity for prompt surgical intervention, even in the apparently hopeless cases. He describes the care necessary to prevent complications, etc.

51. **McGraw Elastic Ligature.**—Tiefenthal commends the elastic ligature, as his experimental tests with it were all pre-eminently favorable.

52. **Bronchoscopy and Pneumotomy.**—Schefold relates that a young man who presented some of the symptoms of tuberculosis was treated in a sanatorium and referred to a hospital with the diagnosis of abscess in the lung. Bronchoscopy revealed a shirt stud in the lung. The stud was removed by operation, but recovery was delayed by empyema., The bronchoscope rendered valuable services during evacuation of the abscess.

54. **New Technic for Obtaining Curative Sera.**—Loeffler's new method for obtaining antibodies was described in an editorial in THE JOURNAL, page 221.

55. **Appendiceal Perforation Peritonitis After Trauma.**—Henning found two fecal concretions in an appendix removed on account of peritonitis following perforation of an ulceration. The patient had been kicked in the abdomen by a horse a few days previously. The fecal concretions in the appendix were evidently old ones, the lumen between them and proximal to both being entirely obliterated, showing their age, and yet they had never caused symptoms. These fecal concretions might never have caused trouble if it had not been for the trauma.

56. **Wearing Out of Parts of Central Nervous Apparatus Without Normal Repair.**—In this third article Edinger considers the wearing out of predisposed nerves from mere functional use. The postsyphilitic affections are analyzed in detail. The anatomic lesion in these seems to be the simple disappearance of the nerve tracts and their substitution by neuroglia. This functional using up of the true nerve substance might be expected in these cases to affect principally the nerves which have most functional demands made on them, and this is what is observed in reality. Sleeping or waking, the spinal cord is constantly receiving impressions from bones, muscles, joints and skin, and the spinal cord suffers first and most. Excessive functioning can be traced in nearly every case of ataxia. It seems difficult to recognize this when a tailor, for example, suffers from ataxia of the legs, but it will probably be found that he lives in an upper story and for years has had to climb several long flights of stairs several times a day. In one instance a syphilitic had had no symptoms of ataxia, but a pedestrian tour, during which he carried a satchel, brought them on, the arm carrying the satchel being first affected and then the legs. After complete rest he recovered, but any over-exercise caused a recurrence of the ataxia. Writers have described cases of tabes without ataxia, but the subjects were women or men with sedentary occupations, none exposed to overexertion. Excessive functioning would probably bring it on in these cases also. The same is true of the postsyphilitic motor symptoms, the pupil reflexes and the disturbances in the eye muscles. Bone and joint affections are also observed from this same wearing out of the nerves without normal repair, and in this respect must be noted the possibility of mechanical destruction of the tissues, which have lost their sensitiveness from the lack of the normal protecting nerve reflexes. In confirmation of this assumption that a connection between the spinal cord and the bones is indispensable for the normal maintenance of the latter, he cites Goltz' experiments. At different sittings long stretches of the spinal cord were resected at intervals of several weeks. At each succeeding operation the vertebræ were easier to cut, until at the last they could be cut with ordinary scissors.

59. **Protection of Wounds with Zinc Chlorid.**—Bröse's researches were conducted on rabbits and demonstrated convincingly that a wound cauterized with a 50 per cent. solution of zinc chlorid is protected against infection. Even with extremely virulent infection, and when an interval of a minute had elapsed between the wound and the cauterizing, the animals were absolutely protected. Notwithstanding this his researches failed to show that zinc chlorid can be regarded as a disinfectant, even in the strongest solutions. His researches further demonstrated that the results of infection differ accordingly as the germs come in light contact with the wound or are driven forcibly into it.

68 *Die Hysterie im Kindesalter (in children). Bruns (Hanover).
69 *Ibid. M. Thiemich (Breslau).

63. **Gastrointestinal Catarrh in Infants.**—The findings in the cadavers of 10 infants indicated that the inflammation in the intestinal mucosa had been mainly restricted to the ileocecal valve. It rarely extended into the small intestine and then but a short distance. In the large intestine the inflammation spread more. In a few cases there was slight inflammation in the duodenum, but, as a rule, the small intestine was free from any decided inflammation. The superficial epithelium and the glands were generally in good order. Bloch's study of the subject is illustrated and the details of his material are carefully sifted.

64. **Enuresis and Pollakiuria in Children.**—When these conditions have no organic cause, Reinach refers them to a neurosis on a psychic basis as the single cause in the majority of cases. Even when hysteria is not evident in the child it can usually be traced—or alcoholism—in the parents. The enuresis may be the only symptom of hysteria, as in children this is apt to be limited to one or two symptoms. There may be merely a latent tendency to hysteria and some inciting cause may arouse it. The nervous centers that control the evacuation of the bladder seem to be especially unstable during childhood. When measures directed against hysteria fail, the condition is probably more of the neurasthenic order, and weak electric currents, hydrotherapy, tonics and country air will gradually put an end to the trouble. Local measures, such as massage from the rectum, raising the foot of the bed, etc., have not proved very successful in his hands.

65. **Later Course of Spondylitis.**—Hugelshofer observed abscesses in two-fifths of the cases of spondylitis at the Children's Hospital at Basle. There was paralysis later in 10 per cent. As this occurs predominantly in cervical spondylitis, and as two thirds of the cases terminated fatally, this must be regarded as the most dangerous type. Amyloid degen-

seen too late for conservative treatment. In 29 of the patients the process was too advanced for any intervention. About 371 patients were treated with resection followed by pouring his iodoform filling into the cavity. This list includes 67 children under 10. All were cured and dismissed in a relatively short time with completely healed wounds and usable limbs. Owing to the infectious nature of the tubercular focus, the danger of its spread should impose its prompt removal as the only rational means of treatment. (See 16 above.)

98. **Significance of Differences in Radial Pulse as Arm is Raised.**—Sorgo is physician in chief to the sanatorium at Alland. He noted in certain of the inmates that the radial pulse in one arm differed from that of the other as the arms were raised or lowered. Comparison of the findings with the known anatomic and physiologic conditions has shown that this difference is due to some pathologic process involving the apex. In a case of endothelioma of the pleura the radial pulse was much stronger on the sound side when the arms were hanging, but this difference vanished as both arms were raised above the head. This vanishing of the difference as the arms are brought into certain symmetrical positions excludes the possibility that the phenomenon is due to anything abnormal in the origin or course of the vessels involved. He has examined 398 patients for this sign, and 31 were found who showed these differences in the radial pulse influenced by the position of the arm. In 10 patients, the difference was marked, but vanished as the arms were raised. In one patient the radial pulse became stronger as the arms were raised above the head, strongest on the left side. In 10 patients there was no difference in the radial pulse as the arms hung down, but a difference became evident as the arms were raised. In 6 there was no difference as the arms hung down, but when they were raised the pulse became very weak, and showed a great difference. In 5 others the difference was marked all the time, but became still more pronounced as the arms were raised vertically. It was instructive to see in some of the cases how this difference in the radial pulse developed under the physician's eyes as the pathologic process in the lungs progressed. The difference noted is probably due to adhesion of the pathologic apex to the subclavian artery. As the arm is raised, the traction on the vessel from the adhesions is corrected as the parts are brought into other positions, and the pulse becomes alike in both arms. A difference in the pulse, therefore, in a case of tuberculosis may be accepted as a sign that retraction of the lung is commencing or has continued for some time.

99. **Physical Investigation in Cholelithiasis.**—Fink's experience at Carlsbad has shown that 66 per cent. of gallstone cases are accompanied by icterus. This emphasizes the necessity for examination of the liver in such cases. Better information is derived when one hand is placed at the back and the liver is pushed up from below toward the palpating fingers of the other hand applied to the liver in front. The hand underneath should not exert an even pressure on the liver, but should push it up in a series of light, gentle upward movements. The special ways to hold the fingers and to take advantage of all the possible findings, even in very corpulent subjects, are described in detail.

100. **Hair Ball in Stomach.**—Ranzi recently had occasion to

101. **Radical Operation for Tubercular Ileocecal Tumors.**—Fröhlich has removed an ileocecal tumor in 3 cases, with recovery of 2 of the patients. In one case the affection was evidently primary; in the others it probably originated from swallowed sputa, the primary lung process not being very advanced. Complete removal of a primary tumor is urgently indicated, and, even in the secondary cases, it is indicated likewise, as the primary focus is liable to heal. This was the satisfactory result in one of his cases. In the fatal case, death resulted from gangrene of an adjacent loop of intestine, after the resection of the tumor.

102. **Treatment of Hypertrophied Prostate.**—Nicholich's success in treating a case of complete retention from hypertrophied prostate was described, with his technic, on page 2,005 of the last volume of The Journal. He has only one patient still alive and healthy out of 10 prostatics operated on by other technics; all the others succumbed to acute or chronic pyelonephritis. His new technic consists in transvesical prostatectomy, after which the bladder is distended with a large amount of iodoform gauze packed in and left for two or three days. This prevents too rapid retraction of the bladder, compresses the walls and thus prevents hemorrhage, while it ensures antisepsis and drains away the urine as soon as it accumulates. He here reports a second case operated on by this technic. The patient's bladder reached above the umbilicus, and he was rapidly restored to health by the operation described.

103. **Medical Radiology as a Separate Branch of the Medical Sciences.**—This article was presented by Holzknecht and Kienböck to sustain their plea for a separate chair for radiology in the medical faculty. Their request was granted, and Vienna is the first city to have special instruction in medical radiology. The two authors were duly appointed instructors in the new branch.

104. **Operative Treatment of Mammary Cancer.**—Meisel reviews the 247 cases of mammary cancer operated on at von Eiselsberg's clinic at Vienna. About 18 per cent. of the patients were permanently cured. The comparative value of the various methods of operating can be determined only by reference to the stage in which the operation was undertaken. As a measure for comparison, he suggests that the percentage of patients who succumb to internal metastasis after an operation without local recurrence, might prove useful as a criterion for determining the actual comparative value of various technics. The proportion of permanent cures with the Volkmann technic was much higher than with the Heidenhain, and approaches closely that obtained by Halsted.

107. **Slow Chloroforming.**—Effertz has observed in Mev[illegible] a mode of administering chloroform which was free from the slightest trace of the stage of agitation and nausea. A few drops of chloroform were poured on a cloth and held at a distance of about four inches from the patient's face. The chloroform was renewed from time to time, and the patient was ready for the operation in two or three hours. This length of time was required before the narcosis was complete. Nearly ten ounces of chloroform were used in each case.

108. **Fibromyomata in Pregnant Uterus.**—Fernwald

nued last year his efforts to stamp out malaria at certain ints on the Austrian shore of the Adriatic, described in these lumns a year ago. The results confirm the possibility of diating the disease in a protected zone in the midst of a ked of malaria, and keeping that zone free from its reim rtation.

113. **Injuries of Thoracic Duct.**—Graff calls attention to e fact that 75 per cent. of the 26 cases of operative injury the thoracic duct on record resulted in recovery when the ct was ligated, with or without suture. On the other hand, y 19 per cent. recovered out of those treated by tamponing ze. A ligature can be thrown around the thoracic duct in neck without the slightest injurious consequences for the anism in general.

14. **Etiology of Spring Catarrh of the Conjunctivae.**—hich reported last year several cases of summer eruptions which the eyes showed the condition of spring catarrh at same time as the skin developed the summer prurigo or roa *vacciniforme*. He proclaimed then that the findings he eyes suggested the probability that they were due like- to the action of sunlight. Dimmer treated a recent case on this assumption. The patient was a young miller, who presented a typical bulbar catarrh, with tions during the summer, not entirely subsiding the cold months. One eye was covered with a black and under this the eye recovered its normal aspect two weeks, except for a slight congestion of the bulbar nctiva. Special spectacles were then worn which pro- the eyes completely against sunlight while not inter- ng th the lids or access of air, and the patient has since manently cured. Dimmer reviews the literature to ermine the geographical distribution of spring catarrh. It ms to harmonize with the assumption of the importance of light in its etiology, or, at least, does not contradict it.

115. **Modern Theories in Regard to Digestion.**—Oefele's pre- s communications on the scientific analysis of the feces n been mentioned in these columns. (See 90 *above*.) He n comments on the multiplicity of the processes that occur he long route from the mouth to the anus, the action of , mouth, throat, gullet, stomach, etc., and the secretions he various glands and organs on the way. In our study hese various processes we must not forget to study the stive function as a whole. Coprology must learn the position of the feces under all kinds of normal conditions, study all the influences which are liable to distuıb its rage composition, before it is possible to detect the patho- conditions and base treatment on their indications.

1. **Functional Kidney Tests.**—In Wildbolz' experience, de- nation of the freezing point of the urine invariably gave results which corresponded in every respect with those of other functional tests and with clinical experience. He describes the details of his most instructive cases. Catheterization of the ureters was always able to locate the site of the lesion, which it would have been impossible to determine by any other means at his command. The freezing point of the urine then revealed whether the other kidney was functioning normally. The results of the operation, both immediate and remote, invariably confirmed the findings.

120. **Elimination of Chloroform by Vomiting.**—It is Gelpke's practice to promote vomiting after most operations requiring chloroform narcosis. He is convinced that this is an important means of elimination of the chloroform. He has the subjects drink copiously of chamomile tea, and observes that the discomfort following the narcosis is much more fleeting when the vomiting is free and unchecked. In 22 cases in which the chloroform narcosis lasted from 20 to 60 minutes, the test for chloroform was always positive. He filters the vomitus and adds a drop of anilin and a little caustic soda, then heats to the boiling point. In the presence of chloroform, there is an unmistakable, pungent odor of isonitril. This test was devised by Bunge of Basle, and is very accurate and sensitive. The vomitus must be kept in an air-tight receptacle until the test is applied to prevent evaporation of the chloroform.

121. **Congenital Defect in the Septum of the Ventricles**—Müller has had a case of congenital defect in the interventricular septum under observation for nineteen years. There has been apparently no disturbances from the defect, not even during a pregnancy. In 8 other cases, the subjects have been seen constantly at intervals for from three to twelve years. The defect in the septum was unmistakably apparent by the physical signs, but there was no cyanosis, and the general health of the subjects did not appear to suffer from this cause. In 2 cases, the diagnosis of persistent ductus arteriosus had been made during life, but examination after death revealed an opening in the interventricular septum. In all these cases the auscultation findings were characteristic, a long, loud, clear bubbling or blowing murmur which terminated with the diastolic sound without any interval. The murmur is characteristic of a jet being forced through a narrow opening under great pressure. A murmur of such loud, rough, rasping quality is never encountered in mitral incompetency nor in case of congenital pulmonary stenosis. It resembles more the murmur frequently heard in case of aortic stenosis. It never had a musical character, but was sometimes audible at a distance of several centimeters. Simultaneously with the murmur, the systolic sound is louder, heard when the ear is slightly raised from the stethoscope. The maximum of the murmur is heard over the left margin of the sternum, below the third rib, exactly over the defect in the septum of the ventricles. In 2 instances it was also loud in the right second interspace. As the murmur is so loud it is audible over the *mitral* and pulmonary or aortic areas, but its maximal point does not correspond with that of either of these. With a single exception, a fine systolic thrill was felt at the point where the murmur was the loudest. In one instance, the thrill was felt also in the second right interspace, in another above the sternum and along the right margin of the sternum below the third and fourth ribs. Another characteristic point is the long stationary persistence of the physical signs. Both sides of the heart are liable to become somewhat enlarged in the course of time. In one of his cases he was able to diagnose dilatation of the pulmonary artery, confirmed by radioscopy, but mistakenly accepted this as a sign of persisting ductus arteriosus. Dilatation of the pulmonary artery was found postmortem in 4 cases on record, and of the pulmonary artery and aorta in 2 others. Eight of his 9 cases were females, and all presented the aspect of good health. In 3 cases severe pulmonary disease developed, in the course of which pronounced cyanosis became manifest, as also in a case of a complicating heart affection. In his patients, the congenital defect was noted
